389. Our knowledge of the dependence of all the vital processes in warm-blooded animals upon the Heat of their bodies, and of the dependence of their calorifying power upon the due supply of material for the combustive process, has received some remarkable additions from the experiments of M. Chossat upon Starvation.* He found that Birds, when totally deprived of food and drink, suffered a progressive, though slight, daily diminution of temperature. This diminution was not so much shown by a fall of their maximum heat, as by an increase in the diurnal variation, which he ascertained to occur even in the normal state (§ 382, II.) The average variation in the *inanitiated* state was about 6° (instead of 1½°) gradually increasing as the animal became weaker; moreover, the gradual rise of temperature, which should have taken place between midnight and noon, was retarded; whilst the fall subsequently to noon commenced much earlier than in the healthy state; so that the *average* of the whole day was lowered by about 4½°, between the *first* and the *penultimate* days of this condition. On the *last* day, the production of heat diminished very rapidly, and the thermometer fell from hour to hour until death supervened: the whole loss on that day being about 25° Fahr., making the *total* depression about 29½°. This depression appears, from the considerations,

the Philadelphia Hospital, however, at the desire of Prof. Dunglison, the temperature of the uterus was not found to be much above that of the vagina; the former being, in three cases, 100°, 102°, and 106°, whilst the latter was 100°, 100°, and 105°. (Prof. Dunglison's "Human Physiology," 8th edit. vol. i. p. 602.)

* "Récherches Expérimentales sur l'Inanition," Paris, 1843; an analysis of this work will be found in the "Brit. and For. Med. Rev.," April, 1844. See also H. Senator, in Reichert and Du Bois-Reymond's "Archiv," 1872, p. 1.

to be presently stated, to be the *immediate* cause of Death.—On examining the amount of loss sustained by the different organs of the body, it was found that 93 per cent. of the *Fat* had disappeared; being all, in fact, which *could* be removed; whilst the nervous centres scarcely exhibited any diminution in weight (§ 80). From the constant coincidence between the entire consumption of the fat, and the depression of temperature, joined to the fact that the duration of life under the inanitiating process evidently varied (other things being equal) with the amount of fat previously accumulated in the body, the inference seems irresistible, that the calorifying process depended chiefly on the materials supplied by this substance. Whenever, therefore, the store of combustible matter in the system was exhausted, the inanitiated animals died, by the cooling of their bodies consequent upon the loss of calorifying power.

390. That this is the real explanation of the fact was shown by the results of a series of very remarkable experiments performed by M. Chossat, with the purpose of testing the correctness of this view. When inanitiated animals whose death seemed impending (death having actually taken place in several instances whilst the preliminary processes of weighing, the application of the thermometer, &c., were being performed), were subjected to artificial heat, they were almost uniformly restored from a state of insensibility and want of muscular power to a condition of comparative activity; their temperature rose, their muscular power returned, they flew about the room, and took food when it was presented to them; and if the artificial assistance was sufficiently prolonged, and they were not again subjected to the starving process, most of them recovered. If they were left to themselves too early, however, the digestive process was not performed, and they ultimately died. Up to the time when they began to take food, their weight continued to diminish; the secretions being renewed, under the influence of artificial heat, sometimes to a considerable amount. It was not until digestion had actually taken place (which, owing to the weakened functional power, was commonly many hours subsequently to the ingestion of the food), that the animal regained any power of generating heat; so that, if the external source of heat was withdrawn, the body at once cooled; and it was not until the quantity of food actually *digested* was sufficient to support the wants of the body, that its independent power of calorification returned. It is to be remembered that, in such cases, the resources of the body are on the point of being completely exhausted, when the attempt at re-animation is made; consequently, it has nothing whatever to fall back upon; and the leaving it to itself *at any time* until fresh resources have been provided for it, is consequently as certain a cause of death as it would have been in the first instance.

391. It can scarcely be questioned, from the similarity of the phenomena, that Inanition, with its consequent depression of temperature, is the immediate cause of death in various Diseases of Exhaustion: and it seems probable that there are many cases in which the depressing cause is of a temporary nature, and in which a judicious and timely application of artificial heat might prolong life until it has passed off, just as artificial respiration is serviceable in cases of narcotic poisoning. It is especially, perhaps, in those forms of Fever, in which no decided lesion can be discovered after death, that this view has the strongest claim to reception; and the beneficial result of the administration of Alcohol in such conditions, and the large amount in which it may be given with impunity, may probably be accounted for on this principle. That it acts as a specific stimulus to the Nervous system, cannot be doubted from its effects on the healthy body; but that it serves as a *fuel* to

keep up the calorifying process, appears equally certain.* Its great efficacy in such cases seems to depend upon the readiness with which it will be taken into the circulation, by a simple act of endosmotic imbibition, when the special Absorbent process, dependent upon the peculiar powers of the cells of the villi (§ 139), is in abeyance. There is no other combustible fluid, whose miscibility and whose density, relatively to that of the Blood, will permit of its rapid absorption by the simple physical process adverted-to.†

392. That the oxidation of certain components of the tissues is the fundamental source of Animal Heat, is further indicated by the close conformity which we everywhere find, between the activity of the Respiratory process and the amount of Heat which is generated; and this not merely when we compare different tribes of animals with each other, but also when we compare the amount of oxygen absorbed and of carbonic acid exhaled by the same individuals under different degrees of external temperature (§ 287, I.) For we find that the system possesses within itself a regulating power, by which the combustive process is augmented in activity when the cooling influence of the surrounding medium is considerable, so that this influence is resisted; whilst the internal fire (so to speak) is slackened, whenever the temperature of the outer air rises so much as to render the same generation of heat no longer requisite. The appetite for food, and especially for those particular forms of it which best afford the combustive pabulum, varies in the same degree; and thus, when supplied with appropriate nutriment, Man is able to brave the severest cold, without suffering any considerable depression in his bodily temperature.—It would seem that the Cutaneous Respiration (§ 289), small as its amount is, promotes those molecular changes on which the maintenance of Animal Heat depends; for it was found by MM. Becquerel and Breschet,‡ and Socoloff,§ that when the hair of Rabbits was shaved off, and a composition of glue, suet, and resin (forming a coating impermeable to the air) was applied to the whole surface, the temperature rapidly fell, notwithstanding the obstacle thus offered to the evaporation of the sweat, whereby, it might be supposed, the temperature of the body would be considerably elevated. In the first rabbit, which had a temperature of 100° before being shaved and plastered, it had fallen to 89½° by the time the material spread over him was dry. An hour afterwards, the thermometer placed in the same parts (the muscles of the thigh and chest) had descended to 76°. In another rabbit, prepared with more care, by the time that the plaster was dry, the temperature of the body was not more than 5½° above that of the surrounding medium, which was at that time 69½°; and in an hour after this the animal died. The varnish appears to act by increasing radiation. Dr. Sanderson‖ found that a rabbit, which in the normal state gave off only 3 heat-units in ten minutes, gave about 20 after varnishing, notwithstanding that in the former case its temperature was constant at 39·5° C., while in the other it sank from 36° to 25°. In Socoloff's experiments, albumin rapidly made its appearance in the urine, and tetanic convulsions occurred before death. Neither wrapping the animal in wool, nor compelling it to breathe oxygen, prevented the fatal result. After death a diffused parenchymatous inflammation of the kidneys was observed, and ulcers were

* See the articles written by M. Baudot in "L'Union Médicale" for Nov. 1863.

† The Author has stated the very striking results of observations which he has had the opportunity of making upon this point, in his Essay on the "Physiology of Temperance and Total Abstinence."

‡ "Comptes Rendus," October, 1841. These experiments were repeated and confirmed by Magendie ("Gazette Médicale," Dec. 6th, 1843).

§ "Centralblatt," 1872, No. 44. ‖ "Handbook for the Physiol. Labor.," 1873, p. 333.

found in the stomach consequent upon profound extravasation. These experiments and observations, though not strictly applicable to man,* place in a very striking point of view the importance of the cutaneous surface as a respiratory organ, even in the higher animals; and they enable us to understand how, when the aërating power of the Lungs is nearly destroyed by disease, the heat of the body is kept up to its natural standard by the action of the skin. A valuable therapeutic indication, also, is derivable from the knowledge which we thus gain, of the importance of the cutaneous respiration; for it leads us to perceive the desirableness of keeping the skin moist, in those febrile diseases in which there is great heat and dryness of the surface, since aëration cannot properly take place through a dry membrane. Of the relief afforded by cold or tepid sponging in such cases experience has given ample evidence.

393. It has been held that the Chemical theory of Calorification is insufficient to account for the total amount of Heat generated by a warm-blooded animal in a given time; this assertion being founded upon the experimental results obtained by M. Dulong. MM. Favre and Silbermann† have shown, however, that the original estimates require correction for the true calorific equivalents of carbon and hydrogen; and that this correction having been made, the heat produced by the combustion of the Carbon which is contained in the carbonic acid expired, and by the combustion of such a proportion of the Hydrogen contained in the exhaled water as may be fairly considered to have undergone oxygenation within the system (§ 294), proves to be adequate to compensate for that which would be dissipated by the evaporation of all the water transpired from the skin and lungs, and also to maintain the temperature of the body itself in an atmosphere of ordinary coolness. And to the combustion heat of carbon and hydrogen we should also add that of those relatively minute quantities of Phosphorus and Sulphur, which also undergo oxidation within the system (§ 366), whereby a small additional amount of heat must be generated.—Through whatever diversity of combinations or successive stages of oxidation these elements respectively pass, in their progress to complete or final oxidation, it may be regarded as an indisputable fact, that *they give out precisely the same amount of heat in the whole, as if they had undergone the most rapid combustion to the same degree of oxidation in pure oxygen;* and thus almost every molecular change in the body, but pre-eminently those which are concerned in the *disintegration* of its textures, and in the elimination of their products by Respiration, participate in the function of Calorification.—The experiments of Ranke,‡ made upon himself, furnish perhaps the best data on which the absolute amount of heat developed in the body can be calculated; and they are by so much the more to be depended upon, as the results agree well with the determinations of Frankland on the amount of heat developed by various kinds of aliment during the act of combustion. It may be remarked that the age of Ranke was twenty-four, his height about six feet, and his weight 154 lbs. The first experiment was made to determine the amount of heat developed on mixed food. The ingesta and the egesta were equal in amount, the weight of the body remaining the same. The numbers represent grammes:—

Exp. 1.—*Production of heat on the first day of total abstinence* from food (commencing 23 hours after the last meal), the ingesta (*i.e.*, consumption of the body itself) calculated from the egesta:—

* Senator, Virchow's "Archiv," Band lxx. Heft ii. p. 12.

† See their Memoirs 'Des Chaleurs de Combustion,' in "Comptes Rendus," tom. xx. xxii.

‡ "Grundzüge der Physiologie," 1874, p. 566.

Ingesta in Grammes.	Egesta.
54·45 Albumin	18·3 Urea.
195·94 Fat	0·24 Uric Acid.

From these data it may be calculated that the daily production of heat amounted to 2012·8 calories.

Exp. II.—*Production of heat on meat diet*, the decomposition of flesh in the body, and the consumption of fat being calculated from the excretions:—

Ingesta.	Egesta.
1832 grm. of Meat, of which only 1300 grm. underwent disintegration.	86 Urea.
70 grm. Fat of Food / 75·14 Fat of Body \ 145·14 Fat.	1·95 Uric Acid.
	99 Fæces.

The daily production of heat produced here was 2799·5 calories.

Exp. III.—*Production of heat on non-nitrogenous diet*, consumption of albumin and deposit of fat in the body calculated from the excreta:—

Ingesta in grammes.	Egesta.
51·55 Body Albumin.	17·1 Urea.
150·00 Fat, of which 81·5 were deposited. So that only 68·5 were burnt off.	0·54 Uric Acid.
	90·0 Fæces.
300 Starch.	
100 Sugar.	

The daily production of heat was here 2059·5 calories. With mixed diet the daily production was about 2200 calories.

Thus during Fasting . . .	2012	Calories	were produced per diem.
On Non-Nitrogenous Diet . .	2059	„	„ „
On Mixed Diet	2200	„	„ „
On abundant Meat Diet . .	2779	„	„ „

According to Senator,* a dog weighing about 12 lbs., fed on a pound of meat per diem, gave off, 16-26 hours after food, 12-14 calories per hour, during which time it excreted from 52 to 57 grains of carbonic acid gas. After fasting for 48 hours, it gave off 11·6 calories, and eliminated 51·7 grains of CO_2, whilst two hours after digestion it gave off 21 calories, and eliminated 79·8 grains of CO_2.

The average of Ranke's experiments on himself gave the number of calories produced per diem at 2200, which is a quantity sufficient to raise 44 pounds of water from the freezing to the boiling point. Helmholtz estimated the amount at 2700.† The mode in which the heat produced is applied, has been estimated as follows—

To the elevation to the temperature of the body of the food ingested	70	Calories	2·6 per cent.
To the warming of the air breathed (air at 32° F.)	140	„	5·2 „
Or if the air be at 68° F.	70	„	2·6 „
To the vaporization of the water discharged by the lungs . . .	397	„	14·7 „
To the radiation from the body and evaporation from the skin .	2195	„	77·5 „

In this calculation Helmholtz estimated that one kilogramme of water (= 2·2 lbs. avoird.) in evaporating from the skin and lungs took up or required 582

* "Centralblatt," 1871, p. 738.

† Or rather 2,700,000, but he considered a calory to be the quantity of heat required to raise 1 gramme of water 1° C., instead of 1 kilogramme, which is 1000 grammes. The mechanical equivalent of heat recently given by Mr. J. P. Joule ("Proceed. Roy. Soc. 1878," vol. xxvii. p. 38) is that, taking a unit of heat, *i.e*, the heat required to raise 1 lb. of water weighed in vacuo from 60° to 61° F., its mechanical equivalent reduced to the sea level is 772·55 foot pounds.

calories, its temperature being already nearly 100° F. Food was considered to be upon the average about 20° F. cooler than the temperature of the body, and to require the same amount of heat to warm it as water. Barral* gives a somewhat different estimate, and considers that of the total heat produced in a man at rest, which, in accordance with Helmholtz, he estimates at 2706·076 calories, 699·801, or 25·85 per cent., are lost in the water evaporated from the skin and lungs; 100·811, or 3·72 per cent., in warming the air breathed; 52·492, or 1·94 per cent., in warming the food; 33·020, or 1·22 per cent., in the solid and fluid excreta; and 1819·952, or 67·22 per cent., by radiation and conduction and mechanical work. Béclard† estimates that a man daily developes sufficient heat to raise 55 lbs. of water from 32° to 212° F.

394. *Local Variations.*—The blood is the means by which the uniformity of the temperature of the body generally is maintained, and its mass enables it to equalize the variable amounts that are produced in the several glands and muscles it traverses, according to whether they are in an active or in a quiescent condition. Warmed during its passage through the abdominal and thoracic viscera, which are in constant functional activity, and which are prevented from cooling by the thick layer of fat that covers the abdominal parietes, the blood carries a high temperature to the extremities, where it becomes gradually reduced, owing to radiation and conduction. If the heat be prevented from escaping from the surface of the body by radiation or evaporation, as in cases where the large size of the animal causes the capillaries of the skin to bear a comparatively small proportion to those of the body generally, or when the animal possesses a thick coating of wool or fat, or is kept in a warm atmosphere, the temperature rises to a high degree: when the opposite conditions are present, the temperature readily falls. Eulenburg and Landois‡ found that stimulation of the cervical sympathetic in rabbits caused cooling of the ear, which lasted from 15—20 secs. after the removal of the stimulation, and was followed by exaltation above the original temperature. Section of the cervical sympathetic caused cooling in the first instance, lasting for ten secs., and amounting to $\frac{1}{10}$ to $\frac{1}{5}$° C., which was followed by a rapid rise of several degrees, whilst stimulation of the peripheral stump immediately caused a fall. Section of the sciatic in a slightly curarized dog caused a rise of 2—3° C. in the corresponding foot, whilst irritation of the peripheral stump caused a fall after a latent period of 15 secs. After a time it sank no further, but slowly rose again. On second stimulation it fell, but after a longer latent stage and to a less degree. The importance of the active circulation of the blood through the vessels of a part in maintaining its temperature is shown by the fact that if the arterial current in the arm be obstructed by compressing the brachial artery, or if the brachial vein be tied, the temperature in the closed hand falls 2° C. (3—6° F.) below that of the opposite one.§ It was also well shown in the experiments of Claude Bernard,‖ that an elevation of temperature constantly took place on one side of the face, when the trunk which unites the Sympathetic ganglia of the neck on that side was cut through; this increase being not only perceptible to the touch, but showing itself by a thermometer introduced into the nostrils or ears, even to the extent of from 7° to 11° Fahr. When the superior cervical ganglion was removed, the same effect was produced, and with yet greater intensity. This difference is main-

tained for many months, and is not apparently connected with the occurrence of inflammation, congestion, œdema, or any other pathological change in the tissues, though the sensibility of the parts thus affected is no less augmented than their temperature; moreover, it is not prevented from manifesting itself by the division of any of the cerebro-spinal nerves of the face. This exaltation of temperature, there can be no doubt, is sufficiently explained by the relaxation of the walls of the smaller arteries (producing a state resembling a permanent "blush"), and the consequent increase in the flow of blood through the part, which has been shown by Dr. Aug. Waller to result from this operation. (See § 238.) A curious experiment made by Bernard tends to show that the quantity of blood taken up by any one organ is supplied to it at the expense of another; and that the excess of heat developed at one point of the body is compensated for by a diminution in some other part. He found that on making a section of the Sympathetic in the neck of a Rabbit, both of whose ears had previously a temperature of 95° F., the temperature rose to 100° F. on the side on which the section was made, whilst it fell to 91° F. on the opposite side. When, however, the peripheral end of the cut nerve was galvanized, the temperature fell in the corresponding ear, and rose in the opposite one.* Local variations of temperature occur in the various organs in consonance with the changes in the circulation in them resulting from the active performance of their duties, or their state of repose. In some instances, however, such variations seem to be independent of changes in the supply of blood.† Thus Schiff‡ has shown that irritation of a sensory nerve in a dog under the influence of curare, and therefore incapable of performing muscular movements, causes increase of the temperature of one or the other hemispheres of the brain, and was independent of changes in the circulation, since it occurred even as late as twelve minutes after the heart's action had ceased. Even irritation of the nerves of special sense will produce this effect, for it was distinctly perceptible in a thoroughly curarized dog before which an umbrella was suddenly opened. In accordance with this, though perhaps other circumstances lead to the increase of temperature, is the observation made by Bernard,§ that if the foot of a dormouse be pinched whilst in a state of hybernation, the temperature rises almost immediately as much as from 60° to 70° F. In opposition to it is the statement made by Horvath,‖ that irritation of a sensory nerve causes depression of the temperature in the rectum.¶ Horvath having observed that mere binding of a rabbit so that it could not move caused a gradual fall of temperature, sometimes to as much as 3° Fahr., at first attributed it to its cramped condition; but further experiments led him to conclude that it was due to the pain experienced by the animal when its limbs were tightly bound. Funke** states that intellectual exertion causes an increase of temperature in the brain. A considerable fall of temperature occurs during the narcotic condition induced by chloroform,†† which is probably partly due to its depressing influence upon the circulation, as well as to its direct action upon the blood corpuscles. In like manner in poisoning by curare, which C. Bernard has shown first paralyses the vaso-motor nerves, causing dilatation of the cutaneous capillaries, and consequent increased loss of heat, and at the

same time a retardation of the movements of the heart and respiratory muscles, a decline of temperature is constantly observed. Jacobson and Landré* have shown that there is similarly a decline in the temperature of the rectum.

395. We have now to inquire whether the *power of generating Heat* is possessed by the Human subject in an equal degree at all ages; this question being very different from that of the *ordinary temperature* of the body at the various periods of life; since an individual who can maintain a high temperature when the surrounding air is moderately warm, may have very little power of bearing continued exposure to severe cold. Important analogical evidence on this point has been supplied by the experiments of Dr. W. F. Edwards upon the lower Mammalia, Birds, &c.† It appears from these to be a general fact, that, the younger the animal, the less is its independent calorifying power. Thus the development of the embryo of all Oviparous animals is entirely dependent upon the amount of external warmth supplied to it. There are many kinds of Birds, which, at the time they issue from the egg, are so deficient in the power of generating heat, that their temperature rapidly falls when they are removed from the nest and placed in a cold atmosphere; it being shown by collateral experiments, that the loss of heat was not to be attributed to the absence of feathers, nor to the extent of surface exposed in comparison with the bulk of the body; and that nothing but an absolute deficiency in the power of generating it, would account for the fall of temperature. This is quite conformable to facts well ascertained in regard to Mammalia. The fœtus, during intra-uterine life, has little power of keeping-up its own temperature; and in many cases it is much dependent on external warmth for some time after birth. The degree of this dependence, however, differs greatly in the various species of Mammalia, as among Birds; being less, in proportion as the general development is advanced. Thus, young Guinea-pigs, which can run about and pick up food for themselves almost as soon as they are born, are from the first independent of parental warmth; whilst, on the other hand, the young of Dogs, Cats, Rabbits, &c., which are born blind, and which do not for a fortnight or more acquire the same development with the preceding, rapidly lose their heat when withdrawn from contact with the body of the mother.

396. In the Human species, it is well known that external warmth is necessary for the Infant, its body rapidly losing heat when exposed to the chilling influence of a low temperature; but the fact is too often neglected (under the erroneous idea of 'hardening' the constitution) during the early years of childhood. It is to be carefully remembered, that the development of Man is slower than that of any other animal, and that his calorifying power is closely connected with his general bodily vigour; and though the infant becomes more independent of it as development advances, it is many years before the standard can be maintained without assistance, throughout the ordinary vicissitudes of external temperature. Especial care is required with regard to the maintenance of the bodily heat by artificial warmth, in the case of children prematurely born; for the earlier the period of embryonic life, the less is the power of calorification that exists for some time after birth. The temperature of a seven months' child, though well swathed and near a good fire, was found by Dr. W. Edwards, within two or three hours after its birth, to be no more than 89·6°. And in some of the recorded instances in which the birth has taken place before the completion of the sixth month, it has not

* "Nederland. Archiv v. Genees en Naturk.," Band ii. p. 355.

† "On the Influence of Physical Agents on Life," part iii. chap. i.

been found possible to maintain the warmth of the infant by exposure to the radiant heat of a fire, the contact of the warm body of another person being the only effectual means of keeping up its temperature.—The fullest measure of calorifying power is possessed by adults; but even in them it is sometimes weakened by previous exertion, so that death by the cooling of the body may occur, when the body is exposed to cold of no great intensity, but in a state of exhaustion of nervous power; a fact which remarkably confirms the views advanced in the preceding paragraph (§ 395). A decrease of calorifying power takes place in advanced age. Old people complain that their "blood is chill;" and they suffer greatly from exposure to cold, the temperature of the whole body being lowered by it.

397. These facts have a very interesting connection with the results of statistical inquiries, as to the average number of deaths at different seasons; the following are recorded by M. Quetelet,* as occurring at Brussels, the *mean* monthly mortality at each age being reckoned as 100.

——	First Month.	2—3 Years.	8—12 Years.	25—30 Years.	50—65 Years.	90 Years and above.
January	1·39	1·22	1·08	1·05	1·0	1·58
February	1·28	1·13	1·06	1·04	1·22	1·48
March	1·21	1·30	1·27	1·11	1·11	1·25
April	1·02	1·27	1·34	1·06	1·02	0·96
May.	0·93	1·12	1·21	1·02	0·93	0·84
June	0·83	0·94	0·99	1·02	0·85	0·75
July	0·78	0·82	0·88	0·91	0·77	0·64
August.	0·79	0·73	0·82	0·96	0·85	0·66
September. . . .	0·86	0·76	0·81	0·95	0·89	0·76
October	0·91	0·78	0·76	0·93	0·90	0·74
November	0·93	0·91	0·80	0·97	1·00	1·03
December	1·07	1·01	0·96	0·97	1·15	1·29

We see from this table that, during the first months of infant life, the external temperature has a very marked influence; for the average mortality during each of the three summer months being 80, that of January is nearly 140, and the average of February and March is 125. This is confirmed by the results obtained by MM. Villermé and Milne-Edwards, in their researches on the mortality of the children conveyed to the Foundling Hospitals in the different towns in France; for they not only ascertained that the mortality is much the greatest during the first three months in the year, but also that it varies in different parts of the kingdom, according to the relative severity of the winter.† As childhood advances, however, the winter mortality diminishes, whilst that of the spring undergoes an increase; this is probably due to the greater prevalence of epidemics at the latter season; for the same condition is observed, in a still more remarkable degree, between the ages of 8 and 12 years,—the time when children are most severely affected by such epidemics. As the constitution acquires greater vigour, and the bodily structure attains its full development, the influence of the season upon

* "Essai de Physique Sociale," tom. i. p. 197.

† Dr. Emerson has shown that, in the Southern and Middle States of North America, the *high summer* temperature is the greatest cause of Infant-mortality: the proportion of deaths during the first year of childhood occurring in the months of June, July, and August, being about *four* times greater than that occurring during the same months in any subsequent year up to the age of 20. The *winter* mortality under the second year scarcely exceeds the average of subsequent years. ("Amer. Jour. of Med. Sci." Nov. 1831.)

mortality becomes less apparent; so that at the age of from 25 to 30 years, the difference between the summer and winter mortality is very slight. The difference reappears, however, in a very marked degree, at a later period, when the general vigour, and the calorifying power, undergo a gradual diminution. Between the ages of 50 and 65, it is nearly as great as in early infancy; and it gradually becomes more striking, until, at the age of 90 and upwards, the deaths in January are 158 for every 74 in July (a proportion of $2\frac{1}{2}$ to 1); and the average of the three winter months is 145, whilst that of the three summer months is only 68, or less than one-half.—The results of the comparisons which have now been carried out for many successive years in the Reports of the Registrar-General, between the variations in the weekly rate of mortality in the Metropolis and the range of atmospheric temperature, present a close coincidence with the foregoing: it being especially to be noted, that the rate of mortality (save during the prevalence of any fatal epidemic) is almost invariably the highest during the winter months; that the increase of deaths at that period is most marked amongst children and old people; and that any extraordinary severity of winter cold constantly produces a great augmentation in the mortality, the weekly number of deaths rising from the average of 1100 (or thereabouts) to 1600 or even 1800, when the mean temperature of the week remains six or eight degrees below the freezing point.

3. *Evolution of Light.*

398. Although the evolution of Light from the living Human subject is an exceptional phenomenon, which has only been observed in morbid states of the body, yet its occasional occurrence is fraught with interest to the Physiologist, on the one hand, from its relation to the Luminosity so common among the lower animals, and on the other from the indications which it affords of the possibility of the formation, even during life, of peculiar phosphuretted compounds, which, being products of incipient decomposition, have been usually supposed to be generated only after death.—There is no doubt that luminous exhalations frequently ascend from burial-grounds; and that the superstitions of many nations respecting "corpse-lights" have to this extent a foundation in fact. A very decided luminosity has been observed to proceed from dissecting-room subjects, the light thus evolved being sufficient to render the forms of the bodies, as well as those of muscles and other dissected parts (which are peculiarly bright), almost as distinct as in the daylight. That this proceeds from the production of a peculiar phosphorescent compound, is shown by the fact, that the luminosity may be communicated to the fingers or to towels, &c., by contact with the luminous surfaces.*—Dr. W. Stokes narrates the case of a patient who was under his observation, some years since, in the Old Meath Hospital, having been admitted on account of an enormous cancer in her breast, which was in an advanced stage of ulceration, the edges being irregular and everted; every part of the base and edges of this cavity was strongly phosphorescent, the light being sufficient to enable the figures on a watch-dial to be distinguished within a few inches; and here also it appeared that the luminosity was due to a particular exudation from the exposed surface. Three cases are recorded by Sir H. Marsh, in which an evolution of light took place from the living body, without any such obvious source of decomposition; all the subjects of these cases, however, were in the last stage

* See Sir Herbert Marsh on "The Evolution of Light from the Living Human Subject" (Dublin, 1842), p. 20.—From this interesting pamphlet most of the statements in this paragraph are derived. See also Herbert Spencer, "Principles of Biology," vol. i. p. 46.

of phthisis; and it can scarcely be doubted that here, as in other diseases of exhaustion, incipient disintegration was taking place during the latter periods of life (§ 82). The light in each case is described as playing around the face, but not as directly proceeding from the surface; and in one of these instances, which was recorded by Dr. D. Donovan,* not only was the luminous appearance perceptible over the head of the patient's bed, but luminous vapours passed in streams through the apartment. It can scarcely be doubted that it was here the *breath* which contained the luminous compound, more especially as it was observed in one of the cases to have a very peculiar smell; and the probability that the luminosity was due to the presence of phosphorus in progress of slow oxidation, is greatly increased by the fact already referred to (§ 295), that the injection of phosphuretted oil into the blood-vessels gives rise to a similar appearance. In repeating this experiment, Sir H. Marsh states that when half an ounce of olive-oil, holding two grains of phosphorus in solution, was injected into the crural vein of a dog, a dense white vapour began to issue from the nostrils even before the syringe was completely emptied, which became faintly luminous on the removal of the lights: and the injection being repeated with the same quantity, the expiration immediately became beautifully luminous, resembling jets of pale-coloured flame pouring forth from the nostrils of the animal. And the luminosity which has been occasionally observed in the urine† may fairly be imputed to an increase in the quantity of unoxidized phosphorus which it seems normally to contain; its liberation taking place at a more rapid rate than its conversion into phosphoric acid, either through excessive excretion or through impeded respiration.‡ A case has been recorded by Kaster in which the body linen was rendered luminous by the perspiration after any violent exercise; and here, too, the cause may be presumed to have been the same.—On the whole, then, we may conclude the occasional evolution of Light from the Human subject, to be the consequence (when not an *electrical* phenomenon) of the production of a phosphorescent compound at the expense of the disintegrating tissues; which compound passes off through one of the ordinary channels of excretion.

4. *Evolution of Electricity.*

399. When the vast variety of changes of condition to which the components of the living body are subjected during the performance of its vital operations, and the impossibility of the occurrence of any of these without some disturbance of Electric equilibrium,§ are duly considered, the wonder

* "Dublin Medical Press," Jan. 15, 1840.

† Casper's "Wochenschrift," 1849, No. 15.—A case has been put on record (Büchner's "Repert., Band viii. p. 342) in which the urine and semen of a patient who was under treatment for impotence and spermatorrhœa, and who was employing phosphorus as a remedy both internally and externally, were observed to be luminous.

‡ The large proportion of intemperate subjects, among those who exhibit this phenomenon, seems to confirm the view already expressed, that the habitual presence of Alcohol in the blood interferes with the oxidation and elimination of excrementitious matters.

§ There is probably no instance of *chemical union* or decomposition, in which the electric condition of the bodies concerned is not altered. Simple *change of form*, from solid to liquid, or from liquid to gaseous, is attended with electric disturbance; and this is greatly increased when any separation takes place between substances that were previously united, as when water containing a small quantity of saline matter is caused to evaporate and to leave it behind. *Heat*, again, is continually generating Electricity; for not only is a current produced by the heating of two dissimilar metals in contact, but also by the unequal heating of two parts of the same bar; and though the effect is most striking in the case of metals, it is by no means limited to them. And so constantly is Electricity generated by the retardation

is, not that such disturbance should be occasionally so considerable as to make itself apparent, but that it should be ordinarily so obscure as only to be detected by the most careful search, and with the assistance of the most delicate instruments. The researches of Prof. Matteucci, M. du Bois-Reymond, and others, however, have now made it apparent that there are no two parts of the body (save those which correspond on the opposite sides), whose electrical condition is precisely the same; and that the differences between them are greater in proportion to the diversity of the vital processes which are taking place in them, and to the activity with which these are being carried on.*— It is by the comparison of the electric states of different secreting surfaces, that such departures from equilibrium are most readily demonstrated. Thus, Donné found that the skin and most of the internal membranes are in opposite electrical states; and Matteucci observed a considerable deflection of the needle of a delicate galvanometer, when the liver and stomach of a rabbit were connected with its platinum electrodes.† More recently, Mr. Baxter has found that if one of the electrodes be placed upon any part of the intestinal surface, and the other be inserted into the branch of the mesenteric vein proceeding from it, a decided deflection of the needle is produced, indicating a positive condition of the blood; but that no effect is produced when the second electrode is inserted into the artery of the part, instead of into its vein. These effects were found to cease after the death of the animals; and could not be attributed, therefore, to mere chemical differences between the blood and the secreted product; but must have arisen from electric disturbance taking-place in the very act of secretion.‡ Scoutetten and Shettle,§ again, have found arterial blood to be positive in its relations to venous blood.— That the process of Nutrition, as well as of Secretion, in parts which are undergoing rapid molecular change, gives rise to electric disturbance, is proved by the experiments of Matteucci and du Bois-Reymond, upon the relative electrical states of different parts of muscles and nerves. If the two extremities of a Muscle, removed from the body of an animal very recently killed, be applied to the two electrodes of a delicate galvanometer, there is usually some deflection of the needle; this being greater, in proportion to the difference in the arrangement of the muscular and tendinous elements at the two extremities. Although the direction of the current is constant for each muscle, yet there is no constant relation between the direction of the currents and the position of the muscles in the body; thus in the *gastrocnemius* of the Frog's leg, the direction is from the foot towards the body, whilst in the *sartorius* it is the reverse. Taking all the muscles of a part together, however, there is usually such a want of balance between the opposite currents,

of *motion*, as in friction, that it is not possible to rub together any two substances, excepting those which are of the most perfect homogeneity (such as the fractured surfaces of a broken bar), without the production of Electric change as well as of Heat.

* Having had an opportunity of witnessing some of the experiments made by M. du Bois-Reymond with a magneto-electrometer of extraordinary sensitiveness, the Author can bear his personal testimony to the fact, that the electricity even of the corresponding fingers of the two hands is very seldom equally balanced, and that the existence of even the slightest scratch or abrasion of surface upon one of them produces a very marked disturbance.

† See M. Becquerel's "Traité de l'Electricité," tom. i. p. 327, and tom. iv. p. 300. From his researches on the electrical organs of the Torpedo, Prof. Babuchin ("Centralblatt," 1870, p. 241) arrives at the conclusion that they are essentially muscles in which the proper muscular or contractile substance is absent, and conversely he regards muscles as electrical organs, in which muscular fibres are introduced between the electrical septa. Marey estimated ("Comptes Rendus," lxxiii. p. 918 and 958) the period of latent excitation of the electrical apparatus of the torpedo to be 1–60th of a second, whilst that of the muscles of the frog is 1–80th.

‡ "Philosophical Transactions," 1848, p. 243.

§ "An Essay on the Electricity of the Blood," 1867.

that a constant current is established in the direction of the strongest and most numerous of the separate muscular currents; this, in the Frog, passes uniformly from the hind-feet towards the head, and was at one time supposed to be peculiar to that animal; but a similar current may almost always be detected in other animals. The muscular current grows feebler and feebler, the longer the muscle has been removed from the body; it is affected by any agents which tend to lower its vitality, and becomes extinct as soon as its contractility ceases. From the experiments of M. du Bois-Reymond, it may be concluded that the current in the arm of Man, when at rest, is from the shoulder towards the points of the fingers. (The special conditions of the 'Nervous' and 'Muscular' currents will be hereafter fully considered in the chapters devoted to the Nerves and Muscles respectively.)

400. Some of the most important parts of the body being thus in a state of constant *disequilibrium* with regard to each other, it is not surprising that the Electric state of the whole should be ordinarily in disequilibrium with that of surrounding bodies. This difference, however, is usually prevented from manifesting itself, in consequence of the restoration of the equilibrium by the free contact which is continually taking place between them; and it is for the most part only when the Human body is insulated, that it becomes apparent. The galvanometer is then affected, however, by the contact of one of its electrodes with the person insulated, and the other with any neighbouring uninsulated body; and also by the contact of the electrodes with the hands of two persons both insulated, who join their other hands together, a difference in the electrical states of the two individuals being thus indicated. The electricity of Man is most commonly positive, and irritable men of sanguine temperament have more free electricity than those of phlegmatic character. The electricity of women is more frequently negative than that of men. There are persons who scarcely ever pull off articles of dress which have been worn next the skin, without sparks and a crackling noise being produced; especially in dry weather, when the electricity of the body is retained, instead of being rapidly dissipated as it is by a damp atmosphere. The effect is usually heightened, if silk stockings and other silken articles have been worn, since these act as insulators. It is doubtless in part attributable to the friction of the articles of dress against each other and against the body; but we can scarcely doubt that it is partly due to the generation of electricity in the body itself, since it bears no constant relation to the former of these supposed causes. Thus a Capuchin friar is mentioned by Dr. Schneider,* who, on removing his cowl, always found a number of shining crackling sparks to pass from his scalp; and this phenomenon continued still perceptible after a three weeks' illness.—The most remarkable case of the generation of Electricity in the Human subject at present known, was recorded some years since in America.† The subject of it, a lady, was for many months in an electric state so different from that of surrounding bodies, that whenever she was but slightly insulated by a carpet or other feebly conducting medium, sparks passed between her person and any object she approached; when most favourably circumstanced, four sparks per minute would pass from her finger to the brass ball of the stove at the distance of $1\frac{1}{2}$ inch. From the pain which accompanied the passage of the sparks, her condition was a source of much discomfort to her. The circumstances which appeared most favourable to the generation of the electricity, were an atmosphere of about 80°, tranquillity of mind, and social enjoyment; whilst a low

* Casper's "Wochenschrift," 1849, No. 15.

† "American Journal of Medical Sciences," January, 1838.

temperature and depressing emotions diminished it in a corresponding degree. The phenomenon was first noticed during the occurrence of an Aurora Borealis; and though its first appearance was sudden, its departure was gradual. Various experiments were made, with a view of ascertaining if the electricity was generated by the friction of articles of dress; but no change in these seemed to modify its intensity.

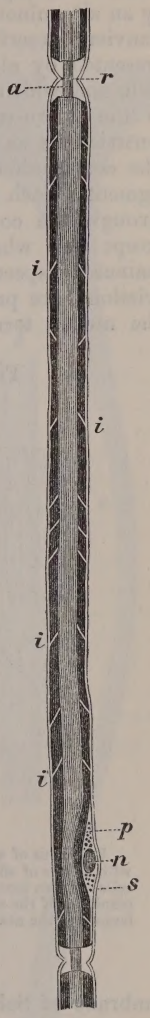
CHAPTER XIII.

OF THE FUNCTIONS OF THE CEREBRO-SPINAL NERVOUS SYSTEM.

1. *General Summary.*

401. The Nervous System of Man, like that of all other Animals, is composed of *ganglionic centres* and *nerve-trunks;* the former being especially composed of 'vesicular substance,' made up of cells which may be spheroidal, fusiform, caudate, stellate, or of almost any variety of shape; the latter consisting entirely of 'nerve-fibres.' If the structure of an ordinary nerve like the Median be examined, it will be found to consist of a framework of connective tissue named the *epineurium*, in which are embedded funiculi, or bundles of nerve fibres of various size. Each of these has its own special sheath of connective tissue, termed the *perineurium*, which is composed of several lamellæ of fibres separated by interlamellary lymph spaces containing a few corpuscles. The funiculi are consequently invested by an epithelium exhibited at Fig. 183, consisting of large flat cells.* On further dissection, the individual fibres are seen to be separated from one another by *endoneurium*, which consists of more or less homogeneous substance, containing numerous minute fasciculi of connective tissue with flattened connective tissue cells. Numerous capillaries, chiefly pursuing a longitudinal course, run in the endoneurium. The living fibres appear as clear, transparent, and highly refractile threads, in which very definite structural characters can be brought into view by the action of various re-agents. After short exposure to the action of air or water, a kind of coagulation occurs, and it then appears that each fibre (Fig. 186) is composed

Fig. 186.



Medullated nerve fibre. *a*, axis-cylinder; *s*, sheath of Schwann; *n*, nerve nucleus, indenting the medullary sheath; *p*, finely granular matter at the poles of the nucleus; *r*, nodes or constrictions of Ranvier, at which point the medullary sheath is interrupted, whilst the axis-cylinder is continued without interruption; *i*, *i*, dissepiments dividing the medullary sheath into segments, corresponding to the inflections of Lantermann.

Török, "Würzburg Physikal-Med. Verhand.," Band iii. 41, and Key and Retzius, "Studien in der Anatomie des Nervensystems," 1876; Lantermann, "Archiv f. Mic. Anat.," Band xiii. p. 1; Kühnt, idem, p. 427; Hennig, "Dissert. Königsberg," 1877; Ranvier, "Leçons," 1878; Klein and Noble Smith, "Atlas of Histology," p. 84, 1880.

(1) of a very delicate sheath, *the sheath of Schwann*, or neurilemma (s, Fig. 186), within which is an oleaginous material termed the *medullary sheath*, or the white medullary substance of Schwann (2), whilst the core or centre is formed by an albuminous cylindrical thread, the *axis-cylinder*, or primitive band (3). Ranvier* describes certain annular constrictions (Fig. 186, *r*) which are presented by all *medullated* nerve-fibres at intervals of about 1-25th of an inch, and which may be brought into view by means of various re-agents, as the picro-carminate of ammonia and osmic acid. He regards these constrictions as being caused by a thickening of the membrane of Schwann. The constrictions divide the white substance of Schwann into "interannular segments," each containing a nucleus. The axis cylinder runs continuously through the constriction without presenting any trace of segmentation, except that when the fibre is treated with nitrate of silver, it presents a laminated aspect, just above and below the constriction. No such constrictions are presented by the fibres of Remak, or non-medullated fibres. The nuclei, termed also nerve corpuscles (*n*, Fig. 186), lie between the

membrane of Schwann and the white substance of Schwann, in which last they are included. They are surrounded by a layer of an albuminoid substance (*p*), which does not stain with osmic acid. In the ganglion cells contained in the brain and spinal cord, and in the ultimate peripheral ramifications of the nerves, both the neurilemma and the white substance of Schwann become indistinct or wholly disappear, whilst the axis cylinder has been observed to break up into fibrils of extreme tenuity, termed elementary or primitive nerve-fibrils;† these are represented in Fig. 190, *c*. The oleaginous

† See Max Schultze Art. on 'The Histology of the Nervous System,' in the first volume of Stricker's "Human and Comparative Histology," Syd. Soc. Trans., 1870 p. 147.

composition of the white or medullary substance is shown by its ready solubility in ether, and by its blackening with osmic acid. It possesses great refrangibility, is extremely extensible, but inelastic, and of a viscid nature, so that when its continuity is interrupted it has little or no tendency to return to its original position.* In addition to the constrictions of Ranvier, it presents a number of septa† (*i*, *i*, Fig. 186), situated at irregular distances from each other, and dividing it into somewhat funnel-shaped medullary segments. The septa appear to be inflections of the sheath of Schwann. The peculiar appearances pre-

sented by the medullary sheath in polarized light suggest that it consists of, or contains, doubly-refracting bodies (crystalline particles‡), the optic axes of which are arranged radially to the primitive band. The axis cylinder is insoluble in ether, and further differs from the white substance of Schwann in readily staining with carmine. When thus stained it appears in transverse sections to be finely fibrillated and to be surrounded by

‡ Klebs, quoted in Kühne's "Phys. Chemie," 1868, p. 339.

an uncoloured line, which by some* has been regarded as a distinct sheath. Ranvier regards it as a thin layer of protoplasm, in conformity with his view that each interannular segment of nerve-fibre is a fat cell traversed by a special structure, the axis cylinder. On this supposition the neurilemma is the cell wall of the fat cell, and between it and the myelin, or white substance of Schwann, is the nucleus with a layer of protoplasm. The myelin represents the oil globule, and the sheath of the axis cylinder the protoplasm of the fat cell reflected on the axis as in enters the cell. Some observers believe that both the axis-cylinder and the medullary sheath are invested by an extremely delicate keratin or horny membrane, the two layers being connected by oblique septa traversing the medullary substance. The axis cylinder occasionally divides (Beale, Ranvier), the division invariably taking place at a nodal point. In addition to the fibres above described, another kind of nerve fibre, named the *Fibres of Remak, or Non-medullated Fibres*, exists, though in far less number in all mixed nerves, though in none of those of special sense. They constitute a large proportion of all sympathetic fibres. The nerve trunks that contain them in larger numbers have a peculiar greyish red and pearly aspect, are striated, but do not readily split up into their constituent fibres, because these anastomose with each other. Nuclei are discoverable at certain points which lie on their surface. The fibres, after being submitted to the action of re-agents, exhibit extremely fine fibrils (resembling *b*, Fig. 189), which probably correspond to the axis cylinders of medullated fibres, and do not appear to possess either myelin or primitive (Schwann's) sheath. No annular constrictions can be made visible in them by any reactions. Bichromate of ammonia causes them to become vacuolated and varicose. Ranvier† considers that the fibres of Remak are formed of elongated masses of protoplasm, the nuclei of which have been pressed towards the periphery, and the bodies of which have been converted into fibrils. The diameter of ordinary nerve-fibres varies from the 1-1500th to 1-20,000th in., but the ultimate fibres above alluded to do not exceed, according to Dr. Beale, 1-50th to 1-100,000th of an inch. On careful treatment with various hardening solutions, the latter may be isolated, but they soon imbibe water and present varicose enlargements (Fig. 190.) These increase in size till the film becomes unrecognisable and disappears. The elasticity of nerve is the same as that of muscle‡, but its extensibility is less, whilst its cohesion is greater—that is, with the same area of transverse section nerves require a greater weight to extend and rupture them than muscles. The precise mode in which the nerves terminate peripherally can scarcely be said to be accurately known in any instance, with the exception, perhaps, of the Pacinian corpuscles.§ In the case of the motor nerves and of the nerves of special sense, considerable differences of opinion exist (which will be hereafter more particularly referred to), as to whether there is a terminal plexus, or whether the nerves end in loops or in free extremities, or become continuous with gland or muscle-cells. Dr. Klein, in follow-

ing out the nerves of the Cornea, seems to have satisfied himself that, in this part at least, the fibres end in free extremities, which run up between the cells on the surface. Nerve fibres are divided into *afferent* or centripetal, which convey impressions to a nervous centre or ganglion; and *efferent* or centrifugal, which conduct impressions from a centre; and central or intramesial Nerves. The Centripetal nerves are subdivided into the sensory nerves and excito-motor nerves, the former conveying impressions which are usually perceived or felt by the individual, while those conveyed by the latter are often unperceived. The Centrifugal fibres are subdivided into motor nerves, distributed to muscles, both striated and unstriated, secretory fibres distributed to glands, and inhibitory nerves, which are capable of arresting or preventing the contraction of muscular tissue. The existence of trophic nerves and of fibres capable of causing active elongation of muscular fibre is still *sub judice*.

Nerve Cells vary much in their form, size, and structure. The simpler kinds are round or oval, the larger polygonal and stellate, (Fig. 191) and it is probable that all possess a nucleus, and give off one, two, or more prolongations, that either intercommunicate with the processes of other cells, or become continuous with the cylinder axis of a nerve-fibre (Fig. 192), gradually ac-

Fig. 192.

quiring a neurilemma, and the white substance of Schwann. In some instances, as in the cells of various parts of the spinal cord (Fig. 191), the subdivision and ramification of the prolongations, which are sometimes called protoplasmic processes, are very remarkable, a close network being formed which pervades the adjoining portion of the nervous tissue. In other instances, only one or two processes can be traced, the cells being then termed uni- and bi-polar. In the sympathetic ganglia of the frog and other animals Dr. Beale, whose researches have been fully confirmed by subsequent inquirers, has observed nerve-cells of great complexity of structure, the chief microscopic features of which are shown in Fig. 193. Such cells are pyriform and nucleated, and from their pointed extremity two fibres arise (a, b), which, on reaching the nervous bundle to which they are distributed, run in opposite directions, thus affording some support to the view maintained by Dr. Beale, that every nerve-fibre, however long its course may be, is a loop arising in, and returning to, the same cell. One of the fibres (a) is usually straight, penetrates into the interior of the cell, and appears like a stalk to the cell; the other (b), which is sometimes double at first, seems to arise from the exterior of the cell, and winds spirally for two or three times round the former. Both fibres at first resemble the axis cylinder of ordinary nerve-fibres, and both may subsequently become dark-bordered, or remain pale, fibres. The spiral fibres bear large oblong nuclei in their course. The descriptions given by Arnold and Courvoisier are in accordance with that by Dr. Beale, except that they state they have traced the straight fibre into the nucleus, and the spiral fibre into a plexus on the exterior of the cell, but which may ultimately be traced into the nucleolus (Fig. 194), so that the two fibres are continuous with one another through the nucleus and nucleolus. The whole cell is invested by a nucleated capsule of connective tissue, proceeding from and continuous with the sheath of Schwann investing the nerve-fibres with which it is in connection.* All our knowledge of the structure and endowments of the ganglionic centres and nerve-trunks renders it probable that they bear a *complementary* relation to each other; the Vesicular substance having for its office to *originate* changes, which it is the function of the Fibrous to *conduct*.

gelatinous lymph, in which connective tissue and elastic fibres form, by which the continuity of the perineurium is restored. According to some, bipolar cells are developed within this sheath, the processes of which unite to form the axis-cylinders of new nerves; the medullary sheath being subsequently developed around them. But Ranvier maintains that the fibres of the peripheric stump atrophy, and that the new fibres proceed from the axis cylinder of the centric stump, which make their way through the cicatrix *into* the degenerated fibres, or run in the connective tissue of the peripheric stump. The changes that occur in the fibres after section are, that they become cloudy, and their margins are less defined. These changes are well marked on the eighth day, soon after which the medullary substance becomes divided into segments, and a kind of coagulation takes place in it, with deposit of fat-globules. In the course of a month or six weeks the medullary substance is reduced to a mass of extremely fine granular molecules of fat-like dust, which finally disappear, and the sheaths collapse. Whether the axis cylinders remain for a long time unaltered,* or also undergo absorption, is still doubtful. The time that elapses before the newly-formed tissue can fulfil the function of a nerve in transmitting sensory and motor impulses is given by various authors at from 7—15 days for the first traces, and 30—90 days for complete return of sensation and motion.† According to Schiff,‡ regeneration of the pneumogastrics may occur even when two inches have been excised. It is questionable whether, after extirpation of a ganglion, new ganglionic corpuscles can be formed; yet, in Brown-Séquard's experiments upon pigeons, it was found that the whole spinal cord would re-unite after division, with almost complete restoration of function. It is to be observed that whilst the distal extremity of a nerve separated from its centre by section undergoes fatty degeneration,§ the proximal portion retains for a considerable period its normal characters, indicating, according to Waller, that the ganglion cell with which it is in relation exercises a certain influence over its nutrition.

403. As regards the *chemistry* of the Nerves, it has been found that the Brain contains about 75 per cent. of water, and 25 of solid residue, of which about 15 parts consist of fatty substances, 7·5 of albuminous compounds, 1·5 of salts, and 1 of extractive matters. The proportions of these constituents, however, are different in different parts of the nervous system; the amount of water, for instance, varying from 70 (in the white) to 85 per cent. (in the grey substance). The large proportion of water may be supposed, as Thudichum suggests, to permit freedom of motion of the ultimate particles within certain limits. It also promotes active changes of nutrition by the penetration of new matter by diffusion, and the rapid removal of effete crystallizable material. The albuminous compounds are chiefly contained in the axis cylinder and in the protoplasm of the cells; they appear to consist of a substance resembling myosin, globulin, and alkali-albumin. Amongst the albuminous are, nuclein and a substance closely resembling kerato-neurin, named kerato-elastin, a substance similar to which is obtained from Schwann's sheath. The fat contained in the grey matter is always much smaller in quantity than that in the white. According to Petrowsky,‖ when dried the grey substance contains more than half of its weight of albumin, the white only one-quarter. The grey substance (dried) contains 18·7 of Cholesterin and fat, and 0·5 of a fat-like body, Cerebrin, the white 51·9 of Cholesterin, and 9·5 per cent. of Cerebrin. Amongst

the chief constituents of the cerebral substance, in addition to Cerebrin, is Lecithin, with the products of its decomposition—viz., glycerin-phosphoric and oleo-phosphoric acids, neurin or cholin ($C_5H_{15}NO_2$), a strongly alkaline colourless fluid forming salts with acids, and other fat-like substances containing phosphorus and soluble in ether; palmitic acid, small quantities of ordinary fat, and volatile fatty acids. Besides these, an albuminous substance resembling Myosin, a substance analogous to Elastin, small quantities of a soluble albuminous substance, coagulating at 147° F., have been found, together with Nuclein, Inosit, Sarkin, Xanthin, Kreatin; Lactic, Uric, and Phosphoric acids, and their combinations with Potash, Lime, and Magnesia; Silicic Acid, Oxide of Iron, Fluorine, small quantities of Alkaline Sulphates, and lastly, Chloride of Sodium.* The quantity of Phosphorus is very large, amounting, according to Borsarelli,† to from 1·352 to 1·790 per cent. Perfectly fresh nerves, when at rest, possess a neutral or perhaps slightly alkaline reaction.‡ According to Ranke, they become acid after tetanus. The white substance of the brain and spinal cord is feebly alkaline or neutral. After exhausting work and after death it is acid. The grey substance is always acid.§

404. As regards the general relations of the principal Centres of the Nervous System of Man, it is only requisite here to remark, that those which make up the Cerebro-Spinal portion of the apparatus have such an intimate structural relation to each other, and so much more frequently act consentaneously than separately, that, notwithstanding the abundant evidence of the diversity of their respective endowments, there is considerable difficulty in the determination of their special functions; since the destruction or removal of any one portion of the Nervous system, not only puts a stop to the phenomena to which that portion is directly subservient, but so deranges the general train of nervous activity, that it often becomes impossible to ascertain, by any such method, what is its real share in the entire performance.—In this difficulty, however, we may advantageously have recourse to the study of the structure and actions of those forms of the Nervous System presented to us among the lower animals, in which its ganglionic centres are fewer and less intimately connected, and in which, therefore, it is more easy to gain an acquaintance with their several endowments. And from an extensive survey of these, we seem able to deduce the following conclusions, which afford the most valuable guidance in the study of the Nervous System of Man :‖—

I. The Nervous System, in its lowest and simplest form, may consist of but a single ganglionic centre,¶ with afferent and motor nerves, whose function is essentially *internuncial;* impressions made upon the afferent fibres exciting respondent or "reflex" movements in the muscles supplied by the motor, without any necessary intervention of consciousness.—Such movements are properly distinguished as *excito-motor.*

II. A simple repetition of such ganglionic centres may exist to any extent, without heterogeneousness of function, or any essential departure from the

§ Gscheidlen, "Archiv f. Physiol.," Band viii. 1873, p. 172.

‖ For a general view of the facts on which these conclusions are based, see "Princ. of Comp. Phys.," chap. xiii.

¶ It may, perhaps, be doubted whether any Animal really exists possessing such a nervous system, and yet not endowed with consciousness. It is quite certain, however, that animals do exist (the Tunicata, for example, which are probably examples of degradation. See Lankester, "On Degeneration," 1880,) in which the actions above referred to are the only ones of which we have any distinct evidence from observation of their habits.

mode of action just indicated; each of these centres may be specially connected by afferent or motor fibres with one segment or division of the body, and may minister peculiarly to *its* actions; but the several centres may be so intimately connected by commissural fibres, that an impression made upon the afferent nerves of any one of them may excite respondent motions in other segments. —This we see effected through the annular gangliated cord of the higher Echinodermata and through the longitudinal g angliated cord of the Arthropods; the disposition of the ganglia and of their connecting cords having reference simply to the general plan of the body.

III. A higher form of the Nervous System is that in which the multiplication of similar parts which are to be alike supplied with nervous power, but to the exercise of a diversity of functions, through the instrumentality of different structures: thus, in the higher Arthropoda and in some of the Mollusca we find ganglionic centres specially set apart for the actions of deglutition and respiration, as well as for those of locomotion; but their *modus operandi* is still the same, these actions being all 'excito-motor,' that is, being performed through the 'reflex' agency of their several ganglionic centres, without the necessary intervention of consciousness. These centres are connected with each other commissurally, when they are required to act with consentaneousness; and it is frequently to be observed in the most developed forms of each type, that they come into actual coalescence, their functional distinctness being still indicated, however, by the distribution of their nerve-trunks.

IV. In all but the very lowest Invertebrata, the Nervous System includes, in addition to the foregoing, certain ganglionic centres, situated in the neighbourhood of, or the entrance to, the digestive cavity, and connected with organs, which, from their more or less close resemblance to our own instruments of special sense, we conclude to be organs of sight, smell, hearing, &c. Now, as we know from our own experience that impressions made upon these organs produce no influence on our actions unless we become *conscious* of them, and as the Invertebrata possess no distinct ganglionic centres of a higher character, it seems to be a legitimate inference, that these 'sensorial' ganglia are the instruments by which the animals furnished with them are rendered cognizant of such impressions, and through which the sensations thus called into existence serve to prompt and direct their movements. What is commonly designated as the 'brain' of Invertebrata (more properly their 'cephalic ganglia') cannot be shown to consist of anything else than an assemblage of *sensorial* centres; and its actions appear to be entirely of a 'reflex' character, such of the movements of these animals as are not excito-motor, being performed (there is strong reason to believe) in direct respondence to sensations excited by internal or external impressions. Such movements, therefore, may be designated as *sensori-motor* or *consensual*. Like the preceding, they do not appear to involve the participation either of Emotion, Reason, or Will; and the proportion which they bear to the actions of the excito-motor kind, seems to correspond pretty closely with the relative development of the cephalic ganglia and of the rest of the nervous system, as is very obvious when the larva and imago states of Insects are compared.— However disjointed the various 'excito-motor' centres may be amongst each other, we uniformly find them connected with the 'sensory' ganglia by commissural tracts; and this anatomical fact, with many phenomena which observation and experiment upon their actions have brought to light, makes it apparent, that besides the reflex actions which are performed through their own direct instrumentality, the sensory ganglia have a participation in those performed through other ganglionic centres. Thus it seems probable that a

stimulus transmitted downwards from the sensory ganglia, to one of the ganglia of the trunk of a Centipede, excites the efferent nerves of that ganglion to call into contraction the muscles supplied by them, just as the excitor influence arriving at that ganglion through its own afferent nerves would do.

405. The whole Nervous System of Invertebrate Animals, then, may be regarded as ministering entirely to *purely-reflex* action; and its highest development, as in the class of Insects, is coincident with the highest manifestations of the 'instinctive' powers, which, when carefully examined, are found to consist entirely in movements of the excito-motor and sensori-motor kinds. When we attentively consider the habits of these animals, we find that their actions, though evidently adapted to the attainment of certain ends, are very far from evincing a *designed* adaptation on the part of the beings that perform them, such as that of which we are ourselves conscious in our own voluntary movements, or which we trace in the operations of the more intelligent Vertebrata. For, in the first place, these actions are invariably performed in the same manner by all the individuals of a species, when the conditions are the same; and thus are obviously to be attributed rather to a uniform impulse, than to a free choice; the most remarkable examples of this being furnished by the economy of Bees, Wasps, and other 'social' Insects, in which every individual of the community performs its appropriate part, with the exactitude and method of a perfect machine. The very perfection of the adaptation, again, is often of itself a sufficient evidence of the unreasoning character of the beings which perform the work; for, if we attribute it to their own intelligence, we must admit that this intelligence frequently equals, if it does not surpass, that of the most accomplished Human reasoner.* Moreover, these operations are performed without any guidance from experience; for it can be proved in many cases that it is impossible for the beings which execute them to have received any instruction whatever; and we see that they do not themselves make any progressive attempts towards perfection, but that they accomplish their work as well when they first apply themselves to it, as after any number of repetitions of the same acts. It is interesting to observe, moreover, that as these instinctive operations vary at different periods of life, so there is a corresponding variation in the structure of the Nervous system. Thus we see that, in the *larva* of the Insect, these operations are entirely directed towards the acquisition of food; and its organs of sense and locomotive powers are only so far developed as to serve this purpose. But in the *imago* or perfect Insect, the primary object is the continuance of the race; and the sensorial and motor endowments are adapted to enable the individual to seek its mate, and to make preparations (frequently of a most elaborate kind) for the nurture of the offspring.—Hence we can scarcely fail to arrive at the conclusion, that the *adaptiveness* of the instinctive operations of Insects, &c., lies in the original construction of their nervous system, which causes particular movements to be executed in direct respondence to certain impressions and sensations. And this view is confirmed by the comparison of such movements with those which, in the Human subject, are most directly concerned in the maintenance of the life of the individual, and in the perpetuation of the race. For we have the evidence of our own consciousness in regard to these, that, however obvious their *purpose* may be, and however complete their *adaptation* to that purpose, they are performed, *not* with any notion of that purpose, but at the prompting of an irresistible impulse which is not only independent of all intelligent appreciation of the result, but may produce its effect without even

* See "Princ. of Comp. Phys.," 4th edit., p. 695.

affecting the consciousness of the agent. Thus the infant seeks the nipple, and puts its muscles into suctorial action, without any knowledge, derived from experience, that by so doing it will relieve the uneasy feeling of hunger; and if we could imagine a man coming into the world with the full possession of all his faculties, we may feel tolerably certain that he would not wait to eat until he had learnt by experience his dependence upon food. We shall see that adult animals whose Cerebral hemispheres have been removed, will eat food that is put into their mouths, although they will not go to seek it; and this is the case with many Human idiots. When the functions of the Brain are destroyed, or in partial abeyance, as in fever, we often observe a remarkable return to the instinctive propensities in regard to food; and the physician frequently derives important guidance with respect to the patient's diet and regimen (particularly as to the administration of wine), from the inclination or disinclination which he manifests. So, in regard to the intercourse of the sexes, the impulse which prompts to it does not arise from a knowledge of the ultimate purposes which it is designed to answer; and the higher powers of the mind are only so far concerned in it, that when the action of the instinctive impulse has led to the formation of a definite idea of the object of desire, the intelligence is prompted to take means for its gratification.*

406. Thus, then, the type of psychical perfection among Invertebrate animals, which is manifested in the highest degree in the Social Insects, consists in the exclusive development of the Instinctive faculty—that is, of *automatic* powers of a very simple kind; in virtue of which, each individual performs those actions to which it is directly prompted by the impulses arising out of impressions made upon its afferent nerves, without any self-control or self-direction; so that it must be regarded as entirely a creature of necessity, performing its instrumental part in the economy of Nature, from no design or will of its own, but in accordance with the plan originally devised by its Creator.

407. On turning to the Vertebrate series, on the other hand, we find that *its* type of psychical perfection—as shown in Man—consists in the highest development of the *Reason*, and in the supreme domination of the *Will*, to which all the 'automatic' actions, save those which are absolutely essential to the maintenance of the Organic functions, are brought under subjection; so that each individual becomes not only a thinking and reflecting, but a self-moving and self-controlling agent, whose actions are performed with a definite purpose which is distinctly before his own view, and are adapted to the attainment of their end by his own intelligence. This, however, is only true of Man in his most elevated state; and not only in ascending the Vertebrate scale, but also in watching the progressive evolution of *his* mental faculties during the earlier periods of his life, may we trace a regular gradation from a condition but little (if at all) in advance of that of the higher Invertebrata, up to that which is displayed in the noblest examples of Humanity. Through the entire series, however, we perceive that the Excito-motor and Sensori-motor portion of the Nervous system constitutes its fundamental and essential part; serving not merely as the instrument whereby those actions

* We have not, perhaps, any right to affirm that there is *nothing whatever* analogous in the Invertebrata to the Reasoning powers and Will of higher animals; but if these faculties have any existence among them, they must be regarded as in a merely rudimentary state, corresponding with the undeveloped condition of the Cerebrum. The only distinct indication of intelligence displayed by Invertebrata, is the slight degree of capacity of "learning by experience" which some of them display; this capacity being limited to the mere formation of *associations* between the psychical called-up by different objects of sense, which we observe to be the first stage in the development of the mental powers in the Human infant.

are performed, which are as necessary among the higher animals as they are among the lower, for the maintenance of the Organic functions; but also as the immediate recipient of all those impressions from without, by which the higher operations of Mind are excited, and as the executant of the actions which proceed from them. But as we ascend the Vertebrate scale, or as we watch the progressive psychical development of the Infant, we find it becoming more and more obvious that the actions are prompted, not so much by simple sensations, as by *ideas* or notions of the objects to which they relate; these ideas being founded, in a large proportion of instances, upon the results of past experience, and the course of action being shaped in accordance with it. In the acts of animals of a still higher grade, as in those of the Child, we can scarcely fail to perceive the manifestation of *reasoning processes* analogous to those which we ourselves perform, and the expressions of some of those *emotional states* of which we are ourselves conscious. The superaddition of these more elevated endowments, in the Vertebrate series, is coincident with the addition of a peculiar ganglionic centre, the *Cerebrum*, to the Sensori-motor apparatus; and the relative proportion which the former bears to the latter, both as to size and to complexity of structure, corresponds so closely with the degree of predominance which the Intelligence possesses over the Instinctive propensities, that it is scarcely possible to doubt that the Cerebrum is the instrument through which this higher form of psychical power is exercised. Much of this exercise, however, may still be *automatic* in its nature; for so long as the current of thought and feeling flows on in accordance with the direct promptings of Suggestion, and without any interference from Volition, may it be considered as a manifestation of the 'reflex' activity of the Cerebrum, which takes the form of a *mental instinct*. This reflex activity manifests itself not only in the psychical operations themselves, but also in muscular movements; and these, when they proceed from simple ideas without any excitement of feeling, may be designated as *ideo-motor:* whilst if they spring from a passion or emotion, they are termed *emotional*. The *mental* instincts, however, are by no means as invariable in the different individuals of the same species, as are what may be termed the *physical* Instincts of that inferior part of the nervous apparatus, which is more closely connected with the maintenance of the Organic life; the particular changes which any given suggestions will excite in each, being partly determined by original constitution, and partly by acquired habits.

408. The superiority of the Mind of Man over that of the most elevated among the lower animals, consists not only in the far greater variety and range of his faculties, but yet more in that dominant power of the Will which enables him to utilize them with the highest effect. In so far as the course of his thoughts and feelings is the mere result of the action of external impressions upon an organization having certain respondent tendencies, must he be considered as irresponsible for his actions, his character being formed *for* instead of *by* him: but in so far as he can exert a Volitional power of directing his thoughts and controlling his feelings, may he rise superior to circumstances, make the most advantageous use of the Intellectual faculties with which he may be endowed, and bring his Moral character more and more into accordance with the highest type which his nature may be capable of attaining in its present sphere of existence. Notwithstanding the evidences of rationality which many of the lower animals present, and the manifestations which they display of emotions that are similar to our own, there is no ground to believe that *they* have any such controlling power; on the contrary, all observation seems to lead to the conclusion that they are under the complete domination

of the ideas and emotions by which they may be for the time possessed, and have no power either of repressing these by a forcible act of Will, or of turning the attention, by a like voluntary effort, into another channel. In this respect, then, their condition resembles that of the Dreamer, the Somnambule, or the Insane patient, in all of whom this voluntary control is suspended, and who (when their minds are susceptible of external impressions) may be so 'played upon' by the suggestion of ideas, that any respondent action consistent with the ordinary mental state of the individual may be evoked by an appropriate stimulus; just as we see in the case of animals that are trained to the performance of particular sets of movements, which are executed in respondence to certain promptings conveyed to them through their sensorium. Now between the complete want of this controlling power of the Will, and the most perfect possession of it, every intermediate gradation is presented by the several individuals which make up the Human species; some persons being so much accustomed, in consequence of the weakness of their Will, to act directly upon the prompting of every transient impulse, that they can scarcely be said to be voluntary agents; and others allowing certain *dominant* ideas or *habitual* feelings to gain such a mastery over them, as to exercise that determining power which the Will alone ought to exert. This gradation may be perfectly traced in children, in whose education the development of the faculty of 'self-control' should be a leading object; and it is also displayed in certain phases of mental Imbecility, which result from a deficiency of the power of voluntarily fixing the attention upon any object of consciousness, and of thus withdrawing it either from external objects that tend to distract the mind, or from notions it has adopted which hold it in subjection.

409. When we apply ourselves to the study of the Cerebro-Spinal Nervous Centres of Man, we find ourselves peculiarly liable to be misled by the great development which the Cerebrum presents, both as to size and to complexity of structure, in proportion to the other centres; and thus it has happened that, through the too exclusive attention commonly paid to *Human* Anatomy, the meaning of the facts brought to light by dissection has been very commonly misapprehended, and many of the physiological interpretations based upon them have been completely negatived by more extended inquiry.—It is only, in fact, by studying the Cerebro-Spinal apparatus in its lowest, as well as in its highest, form, and by bringing the intervening grades into comparison with both extremes, that it is possible to establish what are its fundamental or essential, and what its accessory, parts; and in this way only can such a correspondence be established between the development of a particular structure and the manifestation of a psychical endowment, as may enable the latter to be attributed with any degree of probability to the former. In fact, there is no part of the Human Organism, as to which the advantages of such a comparison are so striking, or in which the value of the "experiments ready prepared for us by Nature" is so much above that of the results of artificial mutilations.

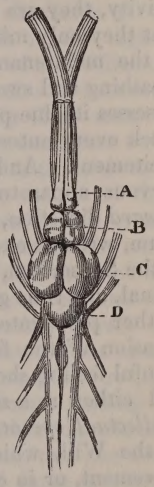
410. *Cerebro-Spinal Nervous Centres.*—Under the guidance, then, of these principles, we find that we may distinguish, as the fundamental part of the Cerebro-Spinal Apparatus of Man, the *Cranio-Spinal Axis*, consisting of the Spinal Cord, the Medulla Oblongata, and the Sensory Ganglia, and altogether constituting the centre of automatic movement.—The Spinal Cord, consisting of a tract of vesicular matter enclosed within strands of longitudinal fibres, and giving off successive pairs of intervertebral nerves which are connected at their roots with both of these components, it is obviously homologous with the gangliated ventral column of the Arthropoda, chiefly differing from it in the continuity of the ganglionic substance which occupies its interior; and each

segmental division of it, which serves as the centre for its own pair of nerves, may be considered, like each ganglion of the ventral column of the Arthropoda, as a repetition of the single 'pedal' or locomotive ganglion of the Mollusca. —The Medulla Oblongata consists of a set of strands, which essentially correspond with the cords that pass round the œsophagus in Invertebrate animals, connecting the cephalic ganglia with the first sub-œsophageal ganglion; but as the whole cranio-spinal axis in the Vertebrata lies *above* the alimentary canal (the trunk being supposed to be in a horizontal position), there is no such divergence of these strands, the only separation between them being that which is known as the 'fourth ventricle.' Interposed among the commissural fibres of the Medulla Oblongata, however, are certain collections of vesicular matter, which serve as the ganglionic centres, governing the calibre of the vessels, and for the movements of respiration and deglutition, the latter corresponding with the 'respiratory' and 'stomato-gastric' ganglia of Invertebrate animals. This incorporation of so many distinct centres into one system, would seem destined in part to afford to all of them the protection of the vertebral column; and in part to secure that consentaneousness of action and that ready means of mutual influence, which are peculiarly requisite in beings in whom the activity of the Nervous system is so predominant. Thus the close connection which is established in the higher Vertebrate animals between the respiratory and the general locomotive apparatus, is obviously subservient to the use which the former makes of the latter in the performance of its functions; whilst, on the other hand, the control which their encephalic centres possess over the actions of the respiratory ganglia, enables the Will to regulate the inspiratory and expiratory movements in the manner required for the acts of vocalization.—Under the term Sensory Ganglia, may be comprehended that assemblage of ganglionic masses lying along the base of the skull in Man, and partly included in the Medulla Oblongata, in which the nerves of the 'special senses,' Taste, Hearing, Sight, and Smell, have their central terminations; and with these may probably be associated the two pairs of ganglionic bodies known as the Corpora Striata and Thalami Optici, into which may be traced the greater proportion of the fibres that constitute the various strands of the Medulla Oblongata, and which seem to stand in the same kind of relation to the nerves of Touch or 'common sensation,' that the Olfactive, Optic, Auditory, and Gustative ganglia bear to *their* several nerve-trunks.

411. Now it is not a little interesting that this Cranio-Spinal axis, which represents in Vertebrate animals the whole nervous system of the Invertebrata (with the exception of the rudiment of the Sympathetic which they possess), should exist in the lowest known Vertebrate animal without any superaddition, and should be sufficient for the performance of all its actions. Such is the case in the curious *Amphioxus*, a little fish which presents not the slightest trace of either Cerebrum or Cerebellum, and in which even the sensory ganglia and the organs of special sense have only a rudimentary existence; and in which, too, the spinal cord is composed of a series of ganglia that are obviously distinct from each other, although in close approximation. And even in the lower Cyclostome Fishes, the condition of the nervous centres is very little above this, save as regards the larger development of the sensory ganglia.—This condition has its parallel, even in the Human species, in the case of Infants which are occasionally born without either Cerebrum or Cerebellum; such have existed for several hours, or even days, breathing, sucking, crying, and performing various other movements; and there is no physiological reason why their lives should not be prolonged, if they be nurtured with sufficient care.

412. In Man, however, as in all the higher Vertebrata, we find superimposed (as it were) upon the Sensory ganglia, and constituting the principal mass of the Encephalon, the bodies which are known as the *Cerebral Hemispheres*, or *Hemispheric Ganglia*. Now when these are so greatly developed as to cover-in and obscure the Sensory ganglia to the degree which presents itself in Man, it is not surprising that the fundamental importance of the latter should not be generally recognized; in Fishes, however, the proportion between the two sets of centres is entirely reversed, the rudiments of the Cerebral Hemispheres (Fig. 195, B) being usually inferior in size to the Optic ganglia (C) alone. Indeed, of the pair of ganglionic masses to which that designation is usually applied, it may be almost positively stated that the greater part is homologous with the Corpora Striata of the Human Brain; it being only in the higher Cartilaginous fishes that a ventricular cavity exists in each of these bodies, separating the thin layer of true Cerebral substance which overlies it from the ganglionic mass which forms its floor. Between these two extremes, a regular gradation is presented in the intermediate tribes.—Now it is a point especially worthy of note, that no sensory nerves terminate directly in the Cerebrum, nor do any motor nerves issue from it; and there seems a strong probability that there is *not* (as formerly supposed) a direct continuity between all or even any of the nerve-fibres distributed to the body, and the Medullary substance of the Cerebrum. For whilst the nerves of 'special' sense have their own ganglionic centres, it cannot be shown that the nervous fibres of 'general' sense, which either enter the cranium as part of the cephalic nerves, or which pass up from the Spinal cord, have any higher destination than the Thalami Optici. So the motor-fibres which pass forth from the Cranium, either into the cephalic nerve trunks, or into the motor columns of the Spinal cord, though commonly designated as *Cerebral*, cannot be certainly said to have a higher origin than the Corpora Striata. And we shall find strong physiological as well as anatomical ground for the belief, that the Cerebrum has no communication with the external world, otherwise than by its connection with the Sensori-motor apparatus; and that even the movements which are usually designated as 'voluntary,' are only so as regards their original source, the stimulus which calls the muscles into contraction being even then immediately issued from the Cranio-Spinal axis, as it is in the movements prompted by the reflex stimulation of an external impression.

Fig. 195.



Brain of *Cod*:—A, olfactive ganglia; B, cerebral lobes; C, optic ganglia; D, cerebellum.

413. Wherever a Cerebrum is superimposed upon the Sensory Ganglia, we find another ganglionic mass, the *Cerebellum*, superimposed upon the Medulla Oblongata. The development of this organ bears a general, but by no means a constant, relation to that of the Cerebrum: for in the lowest Fishes it is a thin lamina of nervous matter on the median line, only partially covering in the 'fourth ventricle;' whilst in the higher Mammalia, as in Man, it is a mass of considerable size, having two lateral lobes or hemispheres in addition to its central portion. The direct communication which the Cerebellum has with both columns of the Spinal cord, and the comparatively slight commissural connection which it possesses with the higher portions of the

Encephalic centres, justify the supposition that it is rather concerned in the regulation and co-ordination of the actions of the former, than in any proper psychical operations; and it will hereafter be shown that the various kinds of evidence afforded by Comparative Anatomy, by Experimental inquiry, and by Pathological observation, all tend to support this view of its function.

414. Now although every segment of the Spinal Cord, and every one of the Sensory Ganglia, may be considered, in common with the Cerebrum, as a true and independent centre of nervous power, yet this independence is only manifested when these organs are separated from each other; either structurally—by actual division; or functionally—by the suspension of the activity of other parts. In their state of perfect integrity and complete functional activity, they are all (at least in Man) in such subordination to the Cerebrum, that they only minister to *its* actions, except in so far as they are subservient to the maintenance of the Organic functions, as in the automatic acts of breathing and swallowing. With regard to every other action, the Will, if it possesses its due predominance, can exercise a determining power; keeping in check every automatic impulse, and repressing the promptings of emotional excitement. And this seems to result from the peculiar arrangement of the nervous apparatus; which causes the excitor *impression* to travel in the *upward* direction, if it meet with no interruption, until it reaches the Cerebrum, without exciting any reflex movements in its course. When it arrives at the Sensorium, it makes an impression on the consciousness of the individual, and thus gives rise to a *sensation;* and the change thus induced, being further propagated from the sensory ganglia to the Cerebrum, becomes the occasion of the formation of an *idea.* If with this idea any pleasurable or painful feeling should be associated, it assumes the character of an *emotion:* and either as a simple or as an emotional idea, it becomes the subject of *intellectual operations*, whose final issue is in a *volitional determination*, or act of the Will, which may be exerted in producing or checking a muscular movement, or in controlling or directing the current of thought.

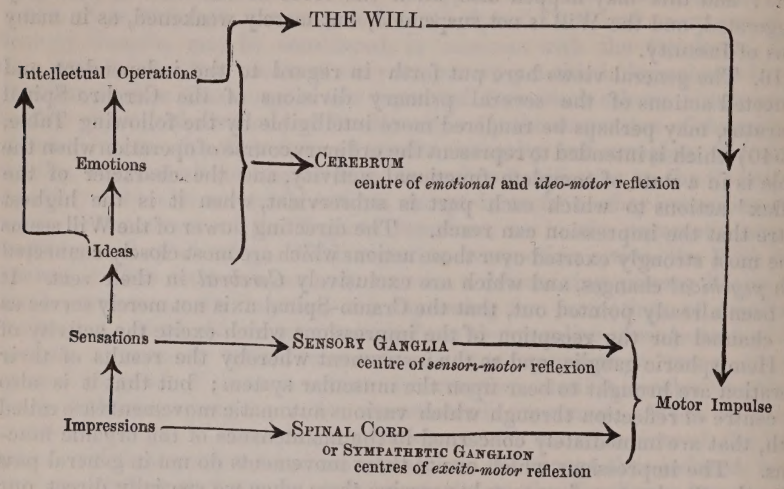
415. But if this ordinary upward course be anywhere interrupted, the impression will then exert its power in a *transverse* direction, and a 'reflex' action will be the result; the nature of any reflex act being dependent upon the part of the Cerebro-Spinal axis at which its ascent had been checked. Thus if the interruption be produced by such division or injury of the Spinal Cord that its lower part is cut off from communication with the encephalic centres, this portion then acts as an independent centre; and impressions made upon it through the afferent nerves proceeding to it from the lower extremities, excite violent reflex movements, which, being thus produced without sensation, are designated as 'excito-motor.'—So, again, if the impression should be conveyed to the Sensorium, but should be prevented by the removal of the Cerebrum, or by its state of functional inaction, or by the direction of its activity into some other channel, from calling forth ideas through the instrumentality of the latter, it may act upon the motor apparatus by the 'reflex' power of the Sensory ganglia themselves; as seems to be the case with regard to those locomotive actions which are maintained and guided by sensations during states of profound abstraction, when the attention of the individual is so completely concentrated upon his own train of thought, that he does not *perceive* external objects, although his movements are obviously guided through the visual and tactile senses. Such actions being dependent upon the prompting of sensations, are 'sensori-motor' or 'consensual.'—But further, even the Cerebrum responds automatically to impressions fitted to excite it to 'reflex' action, when from any cause the Will is in abeyance, and its power

cannot be exerted either over the muscular system or over the direction of the thoughts. Thus in the states of Reverie, Dreaming, Somnambulism, &c., whether spontaneously or artificially produced, *ideas* which take possession of the mind, and from which it cannot free itself, may excite respondent movements; and this may happen also when the force of the Idea is morbidly exaggerated, and the Will is not suspended, but merely weakened, as in many forms of Insanity.

416. The general views here put forth in regard to the independent and connected actions of the several primary divisions of the Cerebro-Spinal apparatus, may perhaps be rendered more intelligible by the following Table, (p. 540) which is intended to represent the ordinary course of operation when the whole is in a state of complete functional activity, and the character of the 'reflex' actions to which each part is subservient, when it is the highest centre that the impression can reach. The directing power of the Will seems to be most strongly exerted over those actions which are most closely connected with *psychical* changes, and which are exclusively *Cerebral* in their seat. It has been already pointed out, that the Cranio-Spinal axis not merely serves as the channel for the reception of the impressions which excite the activity of the Hemispheric ganglia, and as the instrument whereby the results of their operation are brought to bear upon the muscular system; but that it is also the centre of reflection through which various automatic movements are called forth, that are immediately concerned in the maintenance of the organic functions. The impressions which excite these movements do not in general pass on to the Cerebrum; for we only perceive them when we specially direct our attention to them, or when they exist in unusual potency. Thus we are unconscious of the 'besoin de respirer' by which our ordinary movements of respiration are prompted; and it is only when we have refrained from breathing for a few seconds, that we experience a sensation of uneasiness which impels us to make forcible efforts for its relief. Notwithstanding, however, that the Cerebrum is thus unconcerned in the ordinary performance of those automatic movements, yet it can exert a certain degree of control over many of them, so as even to suspend them for a time, though in no instance can it carry this suspension to such an extent as seriously to disarrange the Organic functions; thus, when we have voluntarily refrained from breathing for a few seconds, the inspiratory impulse so rapidly increases in strength with the continuance of the suspension, that it at last overcomes the most powerful effort we can make for the repression of the movements to which it prompts. Now in this and similar cases it would seem as if the Will interfered to prevent that direct transverse passage of the stimulus from the afferent to the efferent nerves through the Cranio-Spinal axis, which constitutes the ordinary line of action for impressions having their origin in the necessities of the Organic or Vegetative life of the individual. That the Will should have a certain degree of control over these movements, is necessary in order that they may be rendered subservient to various actions which are necessary for the due exercise of Man's psychical powers; but that they should not be left dependent upon its exercise, and should even be executed in opposition to it when the wants of the system imperatively demand their performance, constitutes a wise provision for securing Life against the chance of inattention or momentary caprice.

417. The Cerebro-Spinal system is intimately blended with another set of gangliionic centres and nerve-trunks, scattered in different parts of the body, but mutually connected with each other; this is commonly termed the *sympathetic* system; but not unfrequently, from the position of its principal centres, and their evident functional relation to the apparatus of Organic life, the *Visceral*

system. To this system we are probably to refer, not only the Semilunar and Cardiac ganglia (which seem to be its principal centres), with the chain of cranial, cervical, thoracic, lumbar, and sacral ganglia, which are in nearer connection with the Cerebro-spinal system; but also numerous minute ganglia,



which are to be found on its branches in various parts. Moreover, the ganglia upon the posterior roots of the Spinal nerves, and those upon the roots and trunks of certain Cranial nerves, may be ranked with considerable probability under the same category; and if such be the case, those fibres contained in the Cerebro-spinal nerves, which have these as their ganglionic centres, must also be accounted as belonging to the Sympathetic system. On the other hand, there unquestionably exist numerous fibres in the Visceral system, which proceed into it from the Cerebro-spinal system; these, however, are not uniformly distributed, for some of the Visceral nerves contain few or none of them, whilst in others they are numerous. The branches by which the Sympathetic system communicates with the Cerebro-spinal, and which were formerly considered as the *roots* of the Sympathetic system, seem to contain fibres of both kinds—*i.e.*, Cerebro-spinal fibres passing into the Sympathetic, and Sympathetic fibres passing into the Cerebro-spinal. The latter are chiefly, if not entirely, transmitted into the *anterior* branches of the Spinal nerves; the *posterior* branches being apparently supplied with sympathetic fibres from the ganglia on their own posterior roots. Some of these last fibres also pass from the Cerebro-spinal into the Sympathetic system. By these communications, the two systems of fibres are so blended with each other, that it is impossible to isolate them.—The branches proceeding from the Semilunar ganglia are distributed upon the vessels of the abdominal viscera; and those of the Cardiac ganglia upon the heart and vessels proceeding from it. The latter seem to accompany the arterial trunks through their whole course, ramifying minutely upon their surface; and it can scarcely be doubted that they exercise an important influence over their functions. What the nature of that influence may be, however, will be a subject for future inquiry (CHAP. XVII.). It is so evidently connected with the operations of nutrition, secretion, &c., that the designation 'Nervous system of organic life,' as applied to this system, does not seem objectionable, provided that we do not understand it as denoting

the *dependence* of these functions upon it.—The inter-penetration of the Cerebro-spinal system by the Sympathetic is strongly marked by these two circumstances;—that, in some of the lower Vertebrata, the distribution of their trunks cannot be separately distinguished; and that, even in the highest, some of the Glands, of which the secretion is most directly influenced by the condition of the mind, are supplied with most of their nerves from the cerebro-spinal system, the lachrymal and sublingual glands receiving large branches from the fifth pair, and the mammary glands from the intercostal nerves.

418. *Cerebro-Spinal Nerve-Trunks.*—Having thus considered the principal attributes of the ganglionic centres of the Cerebro-Spinal system, we have next to inquire into those of the nerve-trunks which are connected with them. The merit of the discovery of the difference between the *afferent* and *efferent* fibres of the nerves is almost entirely due to Sir C. Bell, who was led to it by a chain of reasoning of a highly philosophical character before any other physiologist came into the field.* Although his first experiments on the Spinal nerves were not satisfactory, he virtually determined the respective functions of their two roots—the posterior as *sensory* (afferent), the anterior *motor* (efferent) —by experiments, and by pathological observations upon the Cranial nerves, some of which contain only one class of fibres to the exclusion of the other. Subsequently his general views were confirmed by the very decided experiments of Müller; but until very recently, some obscurity hung over a portion of the phenomena. It was from the first maintained by Magendie, and has been subsequently asserted by other physiologists, that the posterior and anterior roots of the nerves were *both* concerned in the reception of impressions and in the production of motions; for that, on touching the posterior roots, not only the sensibility of the animal seemed to be affected, but muscular contractions were excited: and that, when the anterior roots were touched, the animal gave signs of pain, at the same time that convulsive movements were performed. These physiologists were not willing, therefore, to admit more than that the posterior roots were *especially* sensory, and the anterior *especially* motor. But the knowledge we now possess of the 'reflex' function of the Spinal Cord enables the former portion of these phenomena to be easily explained. The motions excited by irritating the posterior roots are found to be entirely dependent upon their connection with the Spinal Cord, and upon the integrity of the anterior roots and of the trunks into which they enter; whilst they are not checked by the separation of the posterior roots from the peripheral portion of the trunk; it is evident, therefore, that excitation of the posterior roots does not act immediately upon the muscles, through the trunk of the nerve which they contribute to form; but that it excites a reflex motor impulse in the Spinal Cord, which is propagated through the anterior roots to the periphery of the system.—The converse phenomenon of the apparent sensibility of the anterior roots of the Spinal Nerves or recurrent sensibility, as it is termed, has been investigated by M. Brown-Séquard. If these roots be irritated, the animal usually gives signs of uneasiness; but if they be divided, and the cut ends nearest the centre be irritated, none such are exhibited: whilst they are still shown when the farther ends are irritated, but not if the posterior roots are divided. M. Brown-Séquard† attributes these phenomena to cramp of the muscles supplied by anterior roots, the pain resulting from the violent compression of the extremities of the sensory nerves, which of course is no longer felt when the roots of the latter are divided. Others, however, finding

† "Lectures on the Physiology of the Central Nervous System," 1860; Lecture i.

that signs of pain are still given when the trunk of the mixed nerve is divided, consider that fibres of the posterior root, after descending a short distance, really turn back and enter the anterior root.

419. Every fibre, there is reason to believe, runs a distinct course, between the central organ, with one of the cells of which it is connected at one extremity, and the organ of sense, muscle, or other tissue, in which it either terminates or forms a loop at the other; in the terminal ramifications of the nerves, however, a *subdivision* and plexiform arrangement of the fibres is frequently observable. Although the fasciculi occasionally intermix and exchange fibres with one another (as occurs in a *plexus*), the fibres themselves never inosculate. Each fibre would seem, therefore, to have its appropriate office, which it cannot share with another.—Several objects appear to be attained by the plexiform arrangement. In some instances it serves to intermix fibres, which have endowments fundamentally different; for example, the Spinal Accessory nerve, at its origin, appears to be exclusively motor, and the roots of the Pneumogastric to be exclusively afferent; but by the early admixture of these a large number of motor fibres are imparted to the Pneumogastric, and are distributed in variable proportion, with its different branches; whilst a few of its sensory filaments seem to enter the Spinal Accessory.—In other instances, the object of a plexus appears to be to give a more advantageous distribution to fibres, which all possess corresponding endowments. Thus the Brachial plexus mixes together the fibres arising from five segments of the spinal cord, and sends off five principal trunks to supply the arm. Now if each of these trunks had arisen by itself, from a distinct segment of the spinal cord, so that the parts on which it is distributed had only a single connection with the nervous centres, they would have been much more liable to paralysis than at present. By means of the plexus, every part is supplied with fibres arising from several segments of the spinal cord; and the functions of the whole must therefore be suspended, before complete paralysis of any part can occur from a cause which operates above the plexus. Such a view is borne out by direct experiment; for it has been ascertained by Panizza that, in Frogs, whose Crural plexus is much less complicated than that of Mammalia, section of the roots of one of the three nerves which enter into it produces little effect on the general movements of the limb; and that, even when two are divided, there is no paralysis of any of its actions, all being weakened in a nearly similar degree.* All consideration of the mode in which we make use of our muscles, and of the power which we have over them, leads to the conclusion that each ganglionic centre has a specific and limited sphere of influence, producing certain movements and no others; hence, for the execution of a variety of movements in harmonious combination with each other, it seems requisite that the nervous supply of each muscle should be derived from several different centres; and thus it is, that the complication of plexuses comes to be related to the variety of movements of the parts supplied through them. It is not a little interesting to remark, that arrangements of a similar kind present themselves among the higher Invertebrata.

420. The following statements, in which the doctrines held by Müller† are adopted with some modifications and additions, embody the general principles ascertained by experiment, respecting the transmission of Sensory and Motor

* Striking illustrations of the importance of the plexiform communication of nerves are afforded by such cases as that recorded by Mr. Savory ("Lancet," Aug. 1, 1868), where, after excision of a portion of the musculo-spiral nerve, the sensibility of the parts supplied by it, though impaired, was still to some extent retained, in consequence probably of the communications that exist between the radial and external cutaneous nerves in the forearm. See also W. Gull, 'Gulstonian Lectures on the Nervous System,' in "Medical Times," 1849, p. 372.

† "Elements of Physiology," translated by Dr. Baly; pp. 680, 686.

impressions along the nerves which respectively minister to them. Their *rationale* will be at once understood, from the facts already mentioned in regard to the isolated character of each fibril, and the identity of its endowments through its whole course.

I. When the whole trunk of a *sensory* nerve is irritated, a sensation is produced, which is referred by the mind to the parts to which its branches are ultimately distributed; and if only part of the trunk be irritated, the sensation will be referred to those parts only which are supplied by the fibrils it contains.—This is evidently caused by the production of a change in the sensorium, corresponding with that which would have been transmitted from the peripheral organs of the nerves, had the impression been made upon them. Such a change only requires the integrity of the afferent trunk between the point irritated and the sensorium, and is not at all dependent upon the state of the peripheral part to which the sensations are referred; for this may have been paralysed by the division or other lesion of the nerve, or may have been altogether separated as in amputation, or the relative position of its parts may have been changed, as in autoplastic operations. So, when different parts of the thickness of the same trunk are separately and successively irritated, the sensations are successively referred to the several parts supplied by these divisions. This may be easily shown by compressing the ulnar nerve in different directions, where it passes at the inner side of the elbow-joint.—Still the mind undoubtedly does possess a certain power of discriminating the part of the nerve-trunk on which the impression is made; for whilst this impression is such as to produce sensations that are referred to its peripheral extremities, pain is at the same time felt in the spot itself; and it would seem as if slight impressions are *only* felt in the latter situation, at least in the normal condition of the trunk or fibre. Thus, as it has been well remarked by Volkmann, "if a needle's point be drawn in a straight line across the back, or the thigh, or any part in which the nerves are widely placed, the mind perceives the line of irritation as a straight one; whereas, if it referred all impressions to the ends of irritated fibres, this mode of irritation should be felt in sensations variously scattered about the line, at the points where the nerve-fibres crossed by the needle terminate."*

II. The sensation produced by irritation of a branch of the nerve is confined to the parts to which that branch is distributed, and does not affect the branches which come off from the nerve higher up.—The rationale of this law is at once intelligible; but it should be mentioned that there are certain conditions in which the irritation of a single nerve will give rise to sensations over a great extent of the body. This 'radiation of sensations' seems rather due, however, to a particular state of the *central* organs, than to any direct communication among the peripheral fibres.

III. In general the *motor* influence is propagated only in a centrifugal direction, and not in a retrograde course. It may originate in a spontaneous change in the central organs, or it may be excited in an impression conveyed to them through afferent nerves; but in both cases its law is the same. There is, however, a well-known experiment termed the "paradoxical contraction of muscle," which shows that motor-nerves may under certain circumstances convey impressions centripetally. If a motornerve be selected which divides into two branches (as for example the sciatic of the frog, which divides above the bend of the knee into the tibial and peroneal branches), and a galvanic stimulus be applied to either of these branches, this having been first divided above its insertion into the muscles, the electrotonic state will be

* Kirkes and Paget's "Handbook of Physiology," p. 375.

developed, not merely in the portion of the trunk continuous with that branch, but also in that which is continuous with the other branch, as will be made apparent by the contraction in the muscles supplied by the latter. That this experiment may be free from the possible fallacy resulting from the excitement of reflex action, the trunk of the sciatic nerve should be divided high up, or the spinal cord be destroyed.—Lastly, the occurrence of the negative oscillation of the current, that is to say, the disappearance of the normal current which exists in both sensory and motor nerves, on stimulation of these nerves by any stimulus, affords an additional proof that the particles of nerves can conduct in either direction. In the same way, although as a rule sensory impressions are only conducted towards the new centres, yet some evidence has been obtained to show that they may conduct in an opposite direction. Thus, MM. Philippeaux and Vulpian* divided the hypoglossal and lingual nerves, which are conveniently placed for the experiment, and applied the peripheric extremity of the hypoglossal to the centric extremity of the lingualis. They found that in a few weeks union took place, and that the muscles of the tongue might be excited to contract by an electrical current applied to the lingualis or sensory nerve. MM. Philippeaux and Vulpian drew the conclusion that when the properties of the hypoglossal are abolished by section the lingualis after the lapse of some time acquires motor fibres it did not previously possess. It is to be observed, however, that although the fibres can thus conduct an electrical stimulus there is total loss of *voluntary* control over the lingual muscles, and if the operation be performed on both sides the animal is rendered permanently incapable of protruding its tongue. In Bidder's experiments,† microscopical examination of the nerves showed that the peripheric extremity of the lingualis consisted exclusively of nerve-fibres which had undergone fatty degeneration, whilst in the peripheric portion of the hypoglossal which had united with the centric of the lingualis, the greater number of the fibres presented their normal characters. And this accorded with the fact that, when the nerve was cut during life, the animal gave marked indication of pain, and the same side of the tongue was convulsed.

IV. When the whole trunk of a motor nerve is irritated, all the muscles which it supplies are caused to contract. This contraction evidently results from the similarity between the effect of an artificial stimulus applied to the trunk in its course, and that of the change in the central organs by which the motor influence is ordinarily propagated. But when only a part of the trunk or a branch is irritated, the contraction is usually confined to the muscles which receive their nervous fibres from it; in this instance, as in the other, there is no lateral communication between the fibrils.

421. *Determination of the Functions of Nerves.*—Various methods of determining the functions of particular nerves present themselves to the Physiological inquirer. One source of evidence is drawn from their *peripheral distribution.* For example, if a nervous trunk is found to lose itself entirely in the substance of Muscles, it may be inferred to be chiefly, if not entirely, *motor* or *efferent.* In this manner Willis long ago determined that the Third, Fourth, Sixth, Portio Dura of the Seventh (or Facial), and Ninth cranial nerves, are almost entirely subservient to muscular movement; and the same had been observed of the fibres proceeding from the small root of the Fifth pair, before Sir C. Bell experimentally determined the double function of

* MM. Philippeaux and Vulpian, "Comptes Rendus," 1860, t. ii. p. 363, and idem, t. iii. p. 58. "Archiv. Gén. de Médecine," July, 1863, p. 122. See also Gluge and Thiernesse, Brown-Séquard's "Journal de la Physiologie," 1859, t. ii. p. 686.

† Reichert's "Archiv," 1865, p. 246.

that division of the nerve into which alone it enters. Again, where a nerve passes through the muscles, with little or no ramification among them, and proceeds to a Cutaneous or Mucous surface on which its branches are minutely distributed, there is equal reason to believe that it is of a *sensory* or rather of an *afferent* character. In this manner Willis came to the conclusion, that the Fifth pair of cranial nerves differs from those previously mentioned, in being partly sensory. Further, where a nerve is *entirely* distributed upon a surface adapted to receive impressions of a *special* kind, as the Schneiderian membrane, the retina, or the membrane lining the internal ear, it may be inferred that it is not capable of transmitting any other kind of impressions; for experiment has shown that the *special sensory* nerves do not possess common sensibility. The case is different, however, in regard to the sense of taste, which originates in impressions not far removed from those of ordinary touch; and it is probable that the same nerves minister to both.—Anatomical evidence of this kind is valuable also, not only in reference to the functions of a principal trunk, but even as to those of its several branches, which, in some instances, differ considerably. Thus, some of the branches of the Pneumogastric are especially motor, and others almost exclusively afferent; and anatomical examination, carefully prosecuted, not only assigns the reasons for these functions, when ascertained, but is in itself nearly sufficient to determine them. For the superior laryngeal branch is distributed almost entirely upon the mucous surface of the larynx, the only muscle it supplies being the crico-thyroid; whilst the inferior laryngeal or recurrent is almost exclusively distributed to the muscles. From this we might infer, that the former is an afferent, and the latter a motor nerve; and experimental inquiries (as we have seen, § 275, 276) fully confirm this view. In like manner it may be shown, that the Glosso-pharyngeal is chiefly an afferent nerve, since it is distributed to the *surface* of the tongue and pharynx, and scarcely at all to the muscles of those parts; whilst the pharyngeal branches of the Pneumogastric are chiefly, if not entirely, motor (§ 91). Lower down, however, the branches of the Glosso-pharyngeal cease, and the œsophageal branches of the Pneumogastric are distributed both to the mucous surface and to the muscles, from which it may be inferred that they are both afferent and motor; a deduction which experiment confirms.—We perceive, therefore, that much knowledge of the function of a nerve may be obtained from the attentive study of its ultimate distribution; but it is necessary that this should be very carefully ascertained, before it is made to serve as the foundation for physiological inferences. As an example of former errors in this respect, may be mentioned the description of the Portio dura of the Seventh (or Facial) at first given by Sir C. Bell; for he incorrectly stated it to be distributed to the skin as well as to the muscles of the face, and erroneously regarded it as in part an afferent nerve, subservient to respiratory impressions as well as to motions. In the same manner, from inaccurate observation of the ultimate distribution of the Superior Laryngeal nerve, it was long regarded as that which stimulated to action the constrictors of the glottis.

422. But the knowledge obtained by such anatomical examinations alone is of a very general kind; and requires to be made particular,—to be corrected and modified,—by other sources of information. One of those relates to the *connection of the trunks with the central organs.* The evidence derived from this source, however, is seldom of a very definite character; and, in fact, Physiologists have rather been accustomed to judge of the functions of particular divisions of the nervous centres by those of the nerves with which they are connected, than to draw aid from the former in the determination

of the latter. Still this kind of examination is not without its use, when there is reason to believe that a particular tract of fibrous structure has a certain function, and when the office of a nerve whose roots terminate in it is doubtful. Here again, however, very minute and accurate examination is necessary, before any sound physiological inferences can be drawn from facts of this description; and many instances might be adduced to show, that the real connections of nerves and nervous centres are often very different from their apparent ones.

423. Most important information as to the functions of particular nerves may be drawn from *experimental inquiries;* but these also are liable to give fallacious results, unless they are prosecuted with a full knowledge of all the precautions necessary to insure success. Some of these will be here explained.—In the first place, the endowments of the *trunk* and of the *roots* of a nerve may differ; owing to the admixture, in the former, of fibres derived by inosculation from another nerve (§ 420). Hence, in order to attain satisfactory results, a comparative set of experiments should always be made upon each.—A nerve-trunk may be too hastily considered as *motor* or efferent, on account of the excitation of muscular movements by irritation of its trunk, whilst still in connection with its centre; for such movements may be called forth, not only by the direct influence of the nerve upon the muscles, but also by reflex stimulation acting through the ganglionic centre upon some other nerve. The real nature of such movements can only be determined by dividing the trunk, and then irritating each of the cut extremities. If, upon irritating the end *separated* from the centre, secretion or muscular contraction be produced, it may be safely inferred that the nerve is, in part at least, of an *efferent* character. Should no such result follow, this would be improbable. If, on the other hand, muscular movement or secretion should be produced by irritating the extremity *in connection with* the centre, it will then be evident, that it is occasioned by an impression conveyed *towards* the centre by *this* trunk, and propagated to the muscles or glands by some other; in other words, to use the language of Dr. M. Hall, this nerve is an 'excitor' of motion, not a direct motor nerve. The Glosso-pharyngeal has been satisfactorily determined, by experiments of this kind, performed by Dr. J. Reid (§ 91), to be chiefly, if not entirely, an afferent nerve.—It has been from the want of a proper mode of experimenting, that the functions of the *posterior* roots of the Spinal nerves have been regarded as in any degree motor. If they be irritated, without division of either root, motions are often excited; but if they be divided, and their separated trunks be then irritated, no motions ensue; nor are any movements produced by irritation of the roots in connection with the spinal cord, if the *anterior* roots have been divided. Hence it appears that these fibres do not possess any direct motor powers, but that they convey impressions to the centre, which are reflected to the muscles through the anterior roots.—The same difficulties do not attend the determination of the *sensory* endowments of nerves. If, when the trunk of a nerve is pricked or pinched, the animal exhibits signs of pain, it may be concluded that the nerve is capable of receiving and transmitting sensory impressions from its peripheral extremity. But it not unfrequently happens that this capability is derived by inosculation with another nerve; as is the case with the Facial, which is sensory after it has passed through the parotid gland, having received there a twig from the Fifth pair.

424. The fallacies to which all experiments upon the nerves are subject, arising from the partial loss of their power of receiving and conveying impressions, and of exciting the muscles to action, after death, are too obvious to require more particular mention here; yet they are frequently overlooked.

Of a similar description are those arising from severe disturbance of the system, in consequence of operations; which also have not been enough regarded by experimenters.—As a general rule, *negative* results are of less value than *positive*, but very careful discrimination is often required to determine what *are* negative, and what positive results. Each particular case has its own sources of fallacy, which require to be logically scrutinized; and the only satisfactory proof is derived from the concurrence of every kind of evidence which the nature of the inquiry admits of. Thus in the determination of the functions of a particular nerve-trunk, it should be shown that a certain effect is *constantly* produced by its excitation (under the conditions laid down in the preceding paragraph), and that a corresponding interruption in the action to which it is hence inferred to be subservient, takes place when its continuity has been interrupted: by this double proof, the Glosso-pharyngeal and the Pneumogastric are shown to be the principal, but not the sole, excitors of the movements of Deglutition and Inspiration respectively. But the evidence afforded solely by the interruption of a particular function, after the division of a certain nerve, or the destruction or removal of a nervous centre, is by no means so satisfactory; for this may be occasioned rather by the general effects of the operation, than by the simple lesion of the nervous apparatus. In order to get rid, so far as possible, of this source of fallacy (which particularly affects experiments upon the Encephalic centres, and upon the influence of the nerves upon the viscera), it is desirable to perform comparative experiments, in which the general injury shall be as nearly as possible the same, and the only difference shall lie in the lesion of the nervous system; and to subtract from the entire result all that can be thus shown to be attributable to the general disturbance produced by the operation. But even then, it may happen that the function is only suspended for a time, by the shock which has been induced by the injury to the nerve; and if it should be subsequently renewed without any reunion of the trunk, we have the most convincing proof that whatever degree of participation the nerve may have in it, the action is not essentially dependent upon the integrity of that portion of the nervous apparatus. Such we have seen to be the case in regard to the relation of the Pneumogastric nerves to the secretion of gastric fluid in the walls of the stomach (§ 118).

425. All our positive knowledge of the functions of the Nervous System in general, save that which results from our own consciousness of what passes within ourselves, and that which we obtain from watching the manifestations of disease in Man, is derived from observation of the phenomena exhibited by animals made the subjects of experiments; and in the interpretation of these, great caution must be exercised.—In the first place it must be constantly borne in mind that, except through the *movements* consequent upon them, we have no means of ascertaining whether or not particular changes in the Nervous System, whose character we are endeavouring to determine, are attended with sensation; since we have no power of judging whether or not this has been excited, save by the cries and struggles of the animal made the subject of experiment. Now although such cries and struggles are ordinarily considered as indications of pain, yet it is not right so to regard them in every instance; and the only unequivocal evidence is derived from observation of the corresponding phenomena in the Human subject; since we can there ascertain, by the direct testimony of the individual affected, what impressions produce sensation, and what excite movements independently of sensation. Further, we are not justified in assuming that Consciousness is excited by an irritation, still less that Intelligence and Will are called into exercise by it, merely because movements evidently tending to get rid of its source are performed in correspon-

dence to it. We know that the contractions of the heart and alimentary tube are ordinarily excited by a stimulus, without any sensation being involved; and these movements, like all that are concerned in the maintenance of the Organic functions, have an obvious *design*, when considered either in their immediate effects, or in their more remote consequences. The character of *adaptiveness*, then, in Muscular movements excited by external stimuli, is no proof that they are performed in obedience to sensation; much less that they have a voluntary character. In no case is this adaptiveness more remarkable, than in some of those actions which are not only performed without any effort of the will, but which the will cannot imitate. This is the case, for example, with the act of Deglutition (§§ 89, 90), the muscles concerned in which cannot be thrown into contraction by a voluntary impulse, being stimulated only by impressions conveyed from the mucous surface of the fauces to the Medulla Oblongata, and thence reflected along the motor nerves. No one can swallow, without producing an impression of some kind upon this surface, to which the muscular movements will immediately respond. Now it is impossible to conceive any movements more perfectly adapted to a given purpose, than are those of the parts in question; and yet they are independent, not only of volition but of sensation, being still performed in cases in which consciousness is completely suspended or entirely absent. The act of Sucking in the infant, again, is one in which a number of muscles are called into combined contraction, in a manner which shows a complete adaptation to a given purpose; and yet it is impossible to suppose this adaptation to be *purposive* on the part of the infant itself; more especially as it is shown both by the occurrence of monstrosities, and by experiments made with this object, that no part of the Cranio-spinal axis above the Medulla Oblongata is necessary to it. And in the acts of Coughing and Sneezing (§ 280), we have additional examples of the most *adaptive* movements, executed by a marvellous combination of separate muscular actions, with the obvious purpose of removing sources of irritation from the air-passages; and yet we know by personal experience that this combination is *not* made with any design of our own.

426. The activity of the nervous ganglia and of the nervous cords is alike called into action by the application of *stimuli*. These vary in their nature, and whilst some, as electrical currents, chemical agents, and mechanical pressure, can excite all nerves to action, others, like the vibrations of light and sound, odorous emanations, and heat, appear to be only capable of exciting nerves whose intimate structure especially adapts them for responding to the impressions made by these delicate yet active agents. Although the conducting power of the Nerves for electrical currents is many thousand times less than metallic threads, electricity appears to be a stimulus that very readily affects them, whatever may be their function; exciting not only the various sensory nerves, but being also the most powerful agent with which we are acquainted for inducing the contraction of muscles when applied to the motor nerves that supply them. The effects of electricity upon nerves differ remarkably according to whether a continuous or an induced current is employed. A continuous current passed across a nerve at right angles occasions very slight if any contraction in the muscle supplied by it;* but if it be directed up or down the nerve, contraction commonly occurs at the moment of closing and opening the current, though there is none during its steady and uniform passage.† With an induced or interrupted current, on the contrary, the nerve being kept in a constant state of excitation, the muscles supplied by it pass into a state of

* See Albrecht, Meyer and Giuffré, Pflüger's "Archiv," 1880, Band xxi. p. 462.

† The effects of different kinds of stimulation on various nerves has been studied by Grützner, Pflüger's "Archiv," Band xvii. p. 215.

permanent or tetanic contraction. With a continuous current, contraction is observed to take place not only at the moment of closing and opening, but also when any sudden change, either of increase or decrease, occurs in the intensity of the transmitted current. There is, moreover, a certain strength of current which causes the muscle to pass into a state of Tetanus, 'named galvano-tetanus,' or 'galvano-tonus.' The observation of these phenomena has led to the establishment of a law of nerve physiology, which was originally laid down by Du Bois-Reymond, that the excitation of a nerve is effected not so much by the absolute amount or intensity of the stimulus that is applied to it, as by the modification of this amount from one moment to another. In other words, the excitation of any nerve caused by a stimulus is greater the more rapidly the resulting changes are produced, or the greater they are in a given time; and on the contrary, whatever may be the nature of the stimulus applied, whether mechanical, chemical, thermic, or electrical, neither sensation in a sensory nerve, nor motion in a motor nerve is produced when the passage from one grade of intensity to another is extremely gentle. If, for example, mechanical pressure be so applied to a *motor* nerve as that commencing with the slightest possible contact it may steadily and continuously increase in force even till the nerve be killed at that spot, no convulsions occur in the muscles to which the nerve is distributed.* Muscular contraction only supervenes where the change in the amount of pressure, whether greater or less than that previously present, is so sudden as to produce a kind of shock. In proportion to the energy of the shock or vibration of the particles of the nerve is the effect produced on the muscles. Heidenhain† has constructed an instrument which he has named a "mechanical tetanomotor" which shows that the mechanical stimulus required to excite a nerve is by no means inappreciable. By this instrument it may be demonstrated that a blow so slight as to fail to cause contraction of the muscle supplied by the nerve augments the excitability of the nerve to a subsequently applied stimulus, whilst a somewhat stronger blow diminishes the excitability and conductivity of the nerve at the point struck, and if the blow be violent, both excitability and conductivity are lost at the point struck.‡ The excitability of a nerve is sometimes increased by slight extension,§ whilst violent extension induces tetanic convulsions in the muscles supplied by the stretched nerve. The whole body of a decapitated Frog can sometimes be rendered rigid by throwing it on the ground. In a similar manner, whilst the sudden application of a ligature or of heat to a *sensory* nerve produces acute pain, numbness passing into entire insensibility is the only effect if either be gradually applied,‖ and the same holds good for all other kinds of stimuli. In all instances the passage of a nerve from a state of rest to one of functional activity is accompanied by changes in the chemical constitution of the tissue, and it has been shown that whilst the substance of the brain, spinal cord, and nerves is feebly alkaline or neutral when at rest, it becomes distinctly acid after long and exhausting activity.¶ The molecular and chemical changes seem to be more readily induced in sensory than in motor nerves, the latter requiring more powerful stimulation to call them into play than the former, their equilibrium in other words being more stable. Chauveau** has endeavoured to explain the effects of *electrical currents* on the supposition that

they produce a mechanical commotion in the particles of the nerve. Hence induced currents, which are currents of high tension, and therefore produce a more powerful shock or series of shocks, constitute stronger stimuli than continuous currents, in which the quantity of electricity is large.* On applying a continuous current to a nerve contraction takes place in the muscle it supplies, and a similar contraction occurs at the moment when the current is broken, because at these periods, in accordance with Du Bois-Reymond's law, there is a sudden change in the molecular constitution of the nerve. When the interruptions of a continuous current are about twenty in the second, the muscle has not time to relax between the periods of breaking and making contact and passes into a state of tetanus. The induced currents which are developed in a secondary coil on closing and opening the current in a primary coil, as in the instruments of ordinary construction, are always of short duration, and the molecular movement produced in the nerve is correspondingly rapid and sudden. The duration of the opening does not exceed 0″·0042, whilst the duration of the closing current is 0″·0114. The closing current is comparatively weak, its proportion to the opening current being as 1 : 6, the latter being of higher tension and of shorter duration. Chemical stimuli act but slowly on nerves as compared with their action on muscles, which we may attribute to the sheath of the fibres affording a certain amount of protection to the contents, and thus allowing them to be only gradually acted on. The sensory nerves appear to be much more readily acted on, and by a much greater range of *chemical agents*, than the motor nerves; powerful stimuli for the latter are, however, found in solutions of Soda and Potash, even when not exceeding one tenth per cent., in those of Nitrate of Potash and of Hydrochloric acid, containing 20 per cent., and in concentrated solutions of Ammonia and Alcohol (90 per cent.); the latter, however, rapidly killing the nerve at the point where they have been applied. Bisulphide of carbon, the ethereal oils, and concentrated mineral acids kill the nerve at once, without producing convulsions.† Distilled water applied to nerve-trunks excites no muscular contractions, but if injected into the vessels distributed to a muscle induces very violent convulsions, which are believed by Schiff to be due to the direct effect of the water upon the delicate terminations of the nerves in the muscles. Withdrawal of water from the nerves, if performed either gradually, or with extreme rapidity, produces no effect, but if accomplished with moderate rapidity causes tetanus.‡ The longer the portion of nerve exposed to desiccation, the more violent is the tetanus. The contractions of the muscle begin when the nerve has lost about 4 per cent. of its weight, and its excitability is lost when about 20 per cent. has evaporated.§ The sudden deprivation of water from the nerves may perhaps account in part at least for the spasms of cholera. If too large an amount of water have not been withdrawn, the function of the nerve may be restored on again moistening it. The nerves of frogs, which naturally contain 76·3 per cent. of water, will imbibe a larger quantity till they contain 93·2 per cent. As regards *thermic irritation* as a stimulus for the nerves, it has been shown by Weber that the sensory nerves do not perceive positive temperature, but only variations in the degree of heat of external objects. The influence of variations of temperature on motor nerves has been investigated by Eckhard, who has shown that a temperature of about 130° F.

* For an account of the action of induced and continuous currents on healthy and on paralysed nerve and muscle respectively, see Onimus, Robin's "Journal de l'Anatomie," 1874, translated in full in the "Practitioner," 1874–75.

produces convulsions in frogs, which, however, soon cease; the irritability of the nerves being then lost, though upon cooling they occasionally regain it. Sudden exposure to a temperature of about 25° F. also produces convulsions.* Temperatures intermediate to these limits do not occasion convulsions, but the nerve soon loses its irritability permanently when exposed to a temperature approximating either the higher or the lower extreme.

427. During life, and in the healthy state, the excitability of a motor nerve gradually diminishes from its origin to its distribution in the muscle, so that a stimulus of determinate intensity produces a more energetic contraction of a muscle in proportion to the distance from the muscle that it is applied to the nerve, or, as it is expressed by Pflüger, in proportion to the length of the myopolar portion of nerve. Thus Budge found that to produce the same effect—*i.e.*, the same amount of contraction—it was necessary to apply a stimulus of more than double the strength close to a muscle, than was requisite if the stimulus were applied to the portion of nerve near its origin. The question arises whether the nerve is itself more excitable at the parts nearer the centre, or whether the stimulus does not gain force in its descent, and produce, like an avalanche, an effect greater in proportion to the distance it has traversed. Pflüger expresses himself decisively in favour of the latter supposition. Yet it seems opposed to our ordinary notions of the resistance offered to the passage of currents by conductors, and the phenomenon appears to be more readily explicable on the supposition that the structure of the nerve, and especially of its sheath, may be more delicate in those parts which are more protected, and that it consequently more readily responds there to impressions. Nerves seem to react equally throughout their whole length to chemical stimuli. After death the excitability of the nerves dies out centrifugally, the part in proximity to the muscles remaining longest excitable; immediately after death the excitability of the nerve is for a short period considerably exalted, and this exaltation is shorter in duration in proportion to the distance of the portion of nerve examined from the muscle. If a nerve be divided it becomes temporarily more excitable from the centre towards the periphery, but after a time it ceases to be excitable. This process takes place more rapidly in the proximal than in the peripheral portion of the divided nerve, and the fact is known as the "Law of Ritter-Valli." According to Oehl,† if the needle of a sensitive thermo-electric apparatus be made to traverse a large nerve like the sciatic, a marked increase of temperature occurs at the moment that its functional activity is excited by mechanical or electrical excitation; both Heidenhain and Helmholtz have, however, failed to corroborate this assertion.

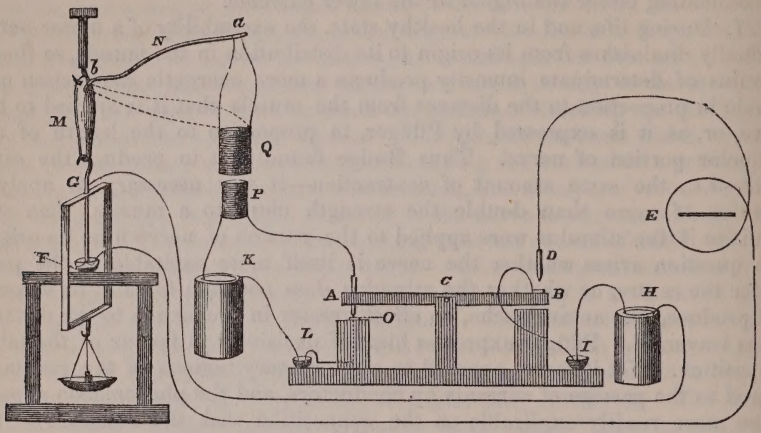
428. The ingenuity of Helmholtz has enabled him to ascertain with some precision the rate at which the change induced by the passage of an electrical current is propagated along a small portion of a nerve. The following figure and description deserve attention, since they exhibit the mode in which physical research can be applied to the most recondite questions of animal life. It is required to measure the time which any excitation takes to travel from the cut end *a* of the nerve N to its point of entrance *b* into the muscle M. As the means of excitation, Helmholtz employs an instantaneous induction current in the following mode:—At the moment that a constant current passing through the coil P, from the

* Eckhard, "Zeitschrift f. rat. Med.," Band x. p. 165; and Harless, ibid., Band viii. p. 122.

† "Annali Universali," tom. cxc. 1864, p. 465; 1865, p. 601; and Lombard, "Med.-Chir. Rev.," Jan. 1869.

battery K, *is broken*, an instantaneous *induced* current passing in the same direction is excited in Q; this is the stimulus acting on the nerve at *a*. The time-measuring current is formed by a second battery H, into some part of whose circuit a galvanometer E is introduced. It is requisite that the

FIG. 196.



closure of this current should be precisely coincident with the opening of the inducing current from K, by which the induced current at Q, or the stimulus, is produced; this is effected by the lever A B C, whose arm A rests on the metal plate O and completes the circuit K L A P. If now the metal point D be forcibly pressed on B, the time-measuring current passing through H I B D E F G will be closed; but at the same instant, from the depression of the arm B, the stimulus will be applied to the nerve through the opening of the inducing current K L A P, which is the result of the elevation of the arm A. But as soon as the stimulus has reached the muscle M, after traversing the nerve N the muscle contracts, raising with it the hook G, which just dips into the cup of mercury F, and consequently breaking the time-measuring current proceeding from the battery H. The *extent* to which the galvanometer needle has been deflected indicates the time during which the current has been flowing through the circuit H I B D E F G, that is, the time which has intervened from the instant of the application of the stimulus to the nerve at *a*, to the moment when the contraction of the muscle breaks that current. A portion of this time is occupied in the transmission of the stimulus from the point *a* to the muscle, and a portion, termed the period of latent excitation, elapses before the muscle responds to the stimulus. In order to ascertain the duration of the former period, the experiment is repeated with this alteration, that the stimulus is applied at *b*, and again the extent to which the needle is deflected is read off; the difference between the two observations then gives the time occupied by the stimulus in passing from *a* to *b*. From numerous experiments with this instrument, Helmholtz arrived at the conclusion that in the Frog, at a temperature between 52° F. and 70° F., the rapidity of the propagation of impressions along motor nerves was from 81 to 126 feet per second, and he estimates the rapidity for human nerve at somewhat more than 200 feet per second.* Other observers

* According to Troitzky, with feeble currents the maximum velocity of propagation is between 50° and 68° Fahr., the rapidity being greatly reduced when the nerve (in the Frog) is warmed to 86° or cooled to 0° Fahr. With strong currents the influence of the temperature upon the conductivity of the nerves diminishes or becomes altogether imperceptible

have obtained the following results:—Hirsch,* 34 meters (111·5 feet); and Schelske,† 29·6 meters (98·4 feet) per second in the Frog. Marey,‡ from 12 to 15 meters (36 to 48 feet) per second in the same animal in winter. Donders and de Jaager, § 26·09 meters (88 feet) for the sensory nerves of Man. And Kohlrausch‖ also from experiments on Man, at 94 meters (308·3 feet) per second. Still more recently Helmholtz,¶ in experiments conducted with Herr Baxt, obtained the number 33·905 m. (111·22 feet) for Man, whilst Place and van West** found that the mean velocity in man was 53 meters (174 feet) per second. In these experiments, as well as in those of Munk, it was found that the rapidity of transmission is greater in the *peripheral* than in the more centrally situated portions of the nervous system. Colin†† has noticed that if the sympathetic ganglia are strongly irritated, reflex movements are immediately produced; but when the excitation is more feeble, a longer time elapses before the movements occur. M. Hirsch has even attempted to determine the relative rapidity with which impressions are transmitted through the nerves of sight, hearing and touch; and the following Table gives his conclusions, in which the term 'Physiological time' signifies the period occupied in the perception of the impression, and in the origination of the motor impulse and execution of the muscular movement by which the time was registered:—

Sense.	Hirsch.		Hankel.‡‡
	Physiological Time.	Mean Variation.	Physiological Time.
1. Hearing	0·149	± 0·025	0·1505
2. Visual perception of a spark	0·200	± 0·016	0·2057
3. Visual perception of the transit of a star	0·077	± 0·025	
4. Touch (left hand)	0·182	± 0·016	0·1546

Thus it will be observed that the perception and registration of an unexpected appearance (spark) occupies much more time than the perception of a slowly-awaited one (transit observation), and one-third more than even the perception of a sound; but the mean variation in the latter case is considerably greater. The value of such experiments in affording information respecting the rapidity of conduction of sensory nerves is, however, but small, since the total or physiological time occupied includes: 1. The time required for the reception of the sensation at the integument. 2. The time required for its transmission through the sensory nerve. 3. The conversion of the sensory impulse into a motor impulse. 4. The transmission of this impulse through the motor nerve, and lastly, the execution of the muscular contraction, each of which events may occupy a variable time.

429. *Electrical Phenomena in Nerve and Muscle.—Pre-existence Theory of Du Bois-Reymond.*—The electrical phenomena presented by the nerves and muscles are in many respects so similar that it will prevent repetition if they

(Pflüger's "Archiv," Band viii. Heft xii.). Both these experiments and the antecedent ones of Helmholtz and Baxt ("Monatsbericht d. Berlin Acad.," 1870, p. 184) show that the influence of temperature must not be overlooked in examining the conductivity of nerves.

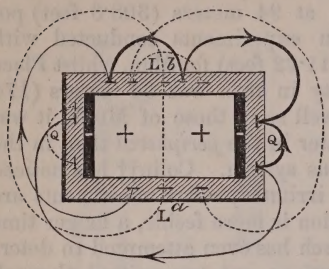
are here considered together.* When a small piece of a nerve-trunk or a cylindrical or fusiform muscle is cut out from the recently-killed body, and is so placed upon the electrodes of a Galvanometer that it touches one of them with its surface (or natural *longitudinal* section), and the other with its cut extremity (or artificial *transverse* section), a considerable deflection of the index is produced, the direction of which always indicates the passage of a current—the natural nerve current—from the interior to the exterior of the nerve-trunk, or from the longitudinal section through the galvanometer to the transverse section. This is shown diagrammatically in Fig. 197. It is indifferent in regard to the direction of the current, whether the central or the peripheral cut extremity be applied to the electrode; and, in fact, the most powerful effect is obtained by doubling the nerve in the middle, and applying both tranverse sections to one electrode, whilst the loop is applied to the other. On the other hand, if the electrodes be applied to the two cut extremities no decided effect is produced; and the same neutrality exists between any two points of the surface of the trunk, equidistant from the middle of its length or equator (*a b*, Fig. 197); but if the points be not equidistant, then a deflection is produced, indicating that the parts nearer the middle are positive to those nearer the extremities. It has not been found possible, owing to the small size of the nerve-trunks experimented on, to test in a similar manner the relative state of different points of their transverse section; but there can be little doubt, from the complete conformity which exists in other respects between nervous and muscular currents, that the same law will be found to prevail in the former as in the latter case—namely, that the points nearer the surface are positive to those nearer the centre. There is no difference between the motor and the sensory nerves in regard to the direction of this current, the existence of which Du Bois-Reymond believed he could demonstrate not only by the galvanometer, but also by the excitement of contractions in the limb of a galvanoscopic frog. Its strength in the Frog he found amounted to 0·022 Daniell, and in the Rabbit to 0·026.—The 'nervous current,' like the muscular, must, he considered, be derived from the electro-motive action of the molecules of the nerve; every integral particle of the nervous substance becoming a centre of electro-motor action, and containing within itself positive and negative elements. It is indifferent what form is assigned to these electro-motive molecules; but it would seem that they must have two negative polar zones, and a positive equatorial zone; a combination of such elements being able to produce all the electrical effects of a nerve in a state of rest. It seems altogether best to suit the phenomena, to suppose that each of these *peripolar*

Fig. 197.



This figure is intended to show the direction of the currents in a columnar portion of nerve or muscle. L, longitudinal section; Q, Transverse section; *a*, *b*, the equator. The barbed lines indicate the direction, and their thickness the force of the currents established, when the electrodes of a galvanometer are applied to the corresponding surfaces. The dotted lines show inoperative arrangements.

* The principal works to be consulted on this subject are Du Bois-Reymond, "Untersuchungen über thierische Electricität," in which a complete list of all previous works is contained. Wundt, "Untersuchungen zur mechanik der Nerven und Nerven centren," 1871. Munk, Hermann, Pflüger, and others in Pflüger's "Archiv f. gesammte Physiologie," 1868–1880. Onimus, "Archives de Physiologie," 1874, and Hermann in the "Handbuch der Physiologie," 1879.

molecules is formed by the combination of two *dipolar* molecules, touching each other by their positive poles,—as in the subjoined Table, which represents a band of four series, A, B, C, D, each series containing four dipolar molecules :—

	1.	2.	3.	4.
A	−+ +−	−+ +−	−+ +−	−+ +−
B	−+ +−	−+ +−	−+ +−	−+ +−
C	−+ +−	−+ +−	−+ +−	−+ +−
D	−+ +−	−+ +−	−+ +−	−+ +−

The relative position of these sets of molecules may, however, under certain circumstances, be changed; and the very remarkable modification of the 'nervous current,' which has been shown by M. du Bois-Reymond to follow severe injuries of the nerve by mechanical, chemical, or thermal agencies, appears to be attributable to such an alteration. If, for instance, a piece of hot metal be brought near to the nerve without touching it, the nervous current will be seen to diminish rapidly, and to have its direction reversed, during which the property possessed by the nerve of conveying irritation to the muscle, though impaired, is not destroyed; and if, whilst in this abnormal state, the nerve be divided, every transverse section is found neutral or positive to the longitudinal section, instead of negative. If the nerve-trunk be then placed between muscles, so as to recover its natural moisture, it will at the same time recover its usual electro-motive power. The same phenomenon is often exhibited in winter, when the frogs serving for experiment have been exposed to cold. The muscle or nerve is then said to present a 'parelectronomic' behaviour, which Du Bois-Reymond explained by assuming that in the case of muscle there is a layer of muscle in contact with the tendon which acts electro-motorially in an opposite direction, and this equals, or even over-compensates, the normal current. To represent this parelectronomic layer, it is only requisite to take away the ultimate molecule of the dipolar molecule, when the last one will turn its positive side to the surface. According to M. du Bois-Reymond, the *current* shown by the entire nerve, when made to form part of a circuit, is only a *derived* current produced by incomparably more intense currents circulating in the interior of the nerve around these ultimate particles, varying greatly in intensity according to the mode in which these particles are arranged; but, generally speaking, increasing both with the length and with the thickness of the nerve.

430. *Alteration Theory of Hermann.*—Hermann is at issue with Du Bois-Reymond on several points. He contends* that in perfectly uninjured animals the nerves and muscles, when at rest, are absolutely destitute of any current, and that all currents that can be made manifest are due to injury inflicted on the tissue, leading to more rapid oxidation at the point injured, followed by death. This part, which extends in the nerves as far as the first constriction ring of Ranvier, then becomes negative to the remainder of the nerve; but if a new section be made, the presence of a current, as Engelmann has shown, can again be made manifest. But supposing a muscle to exhibit a well-marked current, it will be found that on throwing it into a state of tetanic contraction by interrupted electrical stimulation of its nerve, the current undoubtedly diminishes and a negative variation occurs, as stated by Du Bois-Reymond. In the case of a *nerve* a similar wave, which Hermann prefers to term an 'action current,' propagates itself from the point of stimulation in both directions, centripetally as well as peripherically, or if a series of shocks be applied,

* Hermann, "Handbuch du Physiologie," Band i. 1879, p. 169.

a series of such waves is produced. The duration of the action current does not exceed 1·1430th of a second, or a little more. Its velocity in the frog is 28m. per second, and the wave length is about 18mm. Ranke* has shown that the lactic acid generated in nerve and muscle consequent upon the active discharge of function, suffices to abolish and even reverse the ordinary nerve current, which is again restored when the acid is neutralized by an alkali. In the nerves the axis-cylinder, and in muscle the intermediate substance, is the seat of the most active chemical changes, and becomes acid; the doubly refracting muscle substance, and the doubly refracting substance of Schwann remain alkaline. Ranke holds that at the point where a stimulus is applied to a nerve, an increased metamorphosis takes place, accompanied by the formation of lactic acid, which causes regular variation of the muscle current, and a state of increased irritability in the nerves.

431. *Electrotonus of Du Bois-Reymond.*—Electrotonus is the alteration produced in the electromotor condition of the whole of a nerve by the passage of a constant current from a battery through part of it. If a portion of nerve-trunk be so placed (Fig. 198), that it touches one of the electrodes by its transverse section (which may be designated T), and the other by its surface or longitudinal section (L), and a portion of its continuation be included in a galvanic circuit, so that a current shall pass in the direction Z—P, which is *the same* in its direction as that between T—L, then the intensity of the "nervous current" T—L, as indicated by the deflection of the needle of the galvanometer,

FIG. 198.

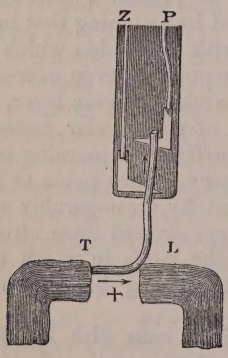


FIG. 199.

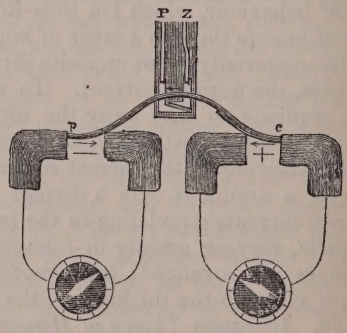


will be found to undergo an increase—"positive phase of electrotonus"—the deflection being greater the longer the portion of nerve through which the constant current passes and the stronger that current is; whilst, on the other hand, if the electric current be passed in a contrary direction P—Z, the intensity of the 'nervous current' T—L will decrease — the "negative phase of electrotonus."—The portion Z—P of the nerve, which is included in the electric circuit, is termed the *excited* portion, and the current passed through it is the *exciting current;* on the other hand, the portion T—L included between the electrodes of the galvanometer is the *derived* portion; and the altered condition of this part, which is produced by the extraneous current (this current having been experimentally proved by M. du Bois-Reymond to exert no influence of its own on the galvanometer), is termed the *electrotonic state* of the nerve. By a proper arrangement, the same exciting current may be made to

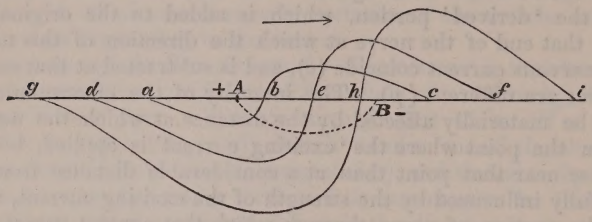
* "Physiologie," 1872, p. 667.

produce the positive phase in one part of a nerve-trunk, and the negative phase in another. Thus if the two extremities of a nerve (Fig. 199, *p* and *c*) be so connected with two galvanometers that both shall develop the 'nervous current,' and an intermediate portion be excited by the transmission of an electric current in the direction Z—P, the nervous current in the 'derived' portion *c* will be increased in intensity, whilst that in the portion *p* will be diminished. Hence it may be inferred, that when any portion of the length of a nerve is traversed by an electric current, besides the usual electro-motive action of the nerve, a new electro-motive action takes place in every point of the nerve by a polarization of its electro-motive elements, which action has the same direction as the exciting current itself; and a current is thus produced in the 'derived' portion, which is added to the original 'nervous current' at that end of the nerve at which the direction of this new current and of the nervous current coincide (*c*), and is subtracted at that end at which the directions are different (*p*). The intensity of the electrotonic condition is found to be materially affected by the distance at which the nerve is examined from the point where the 'exciting current' is applied, being always much greater near that point than at a considerable distance from it. It is also powerfully influenced by the strength of the exciting current, and by the length of the portion of nerve through which that current passes, increasing in intensity with stronger currents, and in proportion to the length of nerve the current has to traverse. These variations in the intensity of the 'nervous current' continue as long as the 'exciting current' lasts, and soon cease when the circuit of that current is broken; a slight enfeeblement of the normal nerve current being apparent for some time after both phases of electrotonus. It is to the induction of the electrotonic state in the nerve supplying it, that the contraction of a muscle is due, which ensues on the completion of the circuit; and to the cessation of this state, that the muscular contraction is due which is consequent upon the interruption of the circuit. Hence the electrotonic changes in the condition of nerves may be observed without previously dividing them.—When, on the other hand, a nerve is 'tetanized' by passing an interrupted and alternating current through a portion of it, the effect is, as in the case of muscle, to produce a *diminution* in its own proper current; the needles of *both* galvanometers, in the arrangement last described, being deflected to the negative side, instead of one going back to zero and the other having its positive deflection increased, as happens when the 'excited portion' is subjected to a continuous and uniform current. The same negative variation of the nervous current has been demonstrated by M. du Bois-Reymond in nerves tetanized by other means, as by the use of strychnia. And the phenomena both of the 'electrotonic state' and of the 'negative variation' are precisely the same, whether motor or sensory nerves be subjected to the experiment; thus making it appear that nerve-force may be transmitted in either direction along each of these orders of nerves. The presence of electrotonus in a nerve may be demonstrated by means of the "physiological rheoscope." For if a portion of nerve, freed from the surrounding tissues, be applied to the sciatic nerve still connected with the muscles of a frog, it will be found that, if the former nerve be excited or stimulated, the muscles in connection with the latter, which is thrown into a state of secondary electrotonus, will contract.

432. *Electrotonus of Pflüger.*—Pflüger has investigated with much care the changes that occur in the excitability of a nerve in a state of electrotonus, or, in other words, through a portion of which an electrical current is passing. Under such circumstances the nerve may be considered to be divided into two

parts, an intra-polar and an extra-polar portion, the latter being again subdivided into that portion situated nearer the nervous centres than the current, or central, and that situated between the current and the muscle, or distal, of the current, the latter being sometimes also called the myopolar portion. As the positive pole of an electrical current is termed the anode, and the negative the kathode, Pflüger has applied the terms anelectrotonus and katelectrotonus to distinguish those conditions established in the portions of nerve in the immediate vicinity of the poles of a constant battery. He has shown that the intra-polar portion of nerve is divided into two zones (Fig. 200); in one of

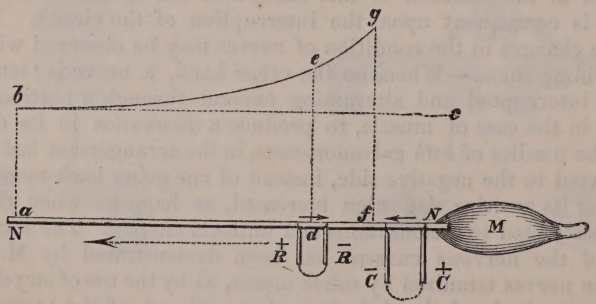
FIG. 200.



A, the Positive, B, the Negative Pole of a constant current applied to a nerve. *a*, *b*, *c*, a curve, showing the effects of a weak current; *d*, *e*, *f*, of a stronger current; *g*, *h*, *i*, of a very strong current. The portion of the curve below the line shows the degree and extent of the depression, the part above of the exaltation of the excitability of the nerve.

these, situated at and near the Positive pole, the excitability of the nerve is diminished, whilst in the other, situated at and near the Negative pole, the excitability is increased. The extent of the portion of nerve in which the

FIG. 201.

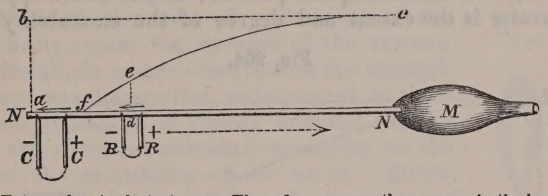


N N, represents a nerve; M, a muscle; C C, the positive and negative poles of a constant current. *a f*, Extra-polar portion of nerve. *d*, Point to which a stimulus, here represented by R R, the positive and negative poles of an interrupted current, but which may be replaced by a mechanical or chemical excitant, is applied. *b*, *c*, indicates the line of normal excitability, supposed for the sake of simplicity to be equal throughout the whole length of the nerve, though in reality it is greater, and should therefore ascend towards *b*. *b*, *e*, *g*, indicates the curve of augmented excitability in the extra-polar portion of nerve, the amount of increase being greatest at the kathode—as at *g*, less marked at *e*, and falling to its ordinary amount at *b*.

excitability is lowered, the positive or anelectrotonic zone, is small in proportion to the weakness of the current; whilst the negative or katelectronic zone, in which the excitability is exalted, is correspondingly large; so that, with very weak currents, nearly the whole of the intra-polar portion of the nerve is in a state of exalted excitability, whilst with strong currents the intra-polar portion of the nerve is almost wholly in a state of depressed excitability. The same conditions of exalted or depressed excitability also extends for a considerable distance beyond the poles—*i.e.*, in the extra-polar portions of the nerves in

both directions. The mode of determining the variations in the excitability of the nerve at the two poles may be understood with the aid of the diagram (Fig. 200). In Fig. 201, c c represents the poles of the constant or polarizing currents by means of which the state of electrotonus is established, and R R those of the exciting current, or that by means of which the excitability of the nerve is tested; the latter may be replaced by a mechanical stimulus. Eckhard employed a solution of common salt. Before throwing the nerve into an electrotonic state by the application of the poles of the constant current, a few trials are made to ascertain what is the weakest stimulus which, when applied at *d*, will produce contraction in the muscle. When this is known,

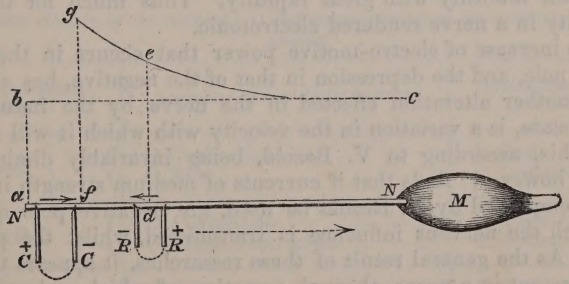
Fig. 202.



Centrifugal Extra-polar Anelectrotonus. The references are the same as in the last Fig., except that *a f* represents the intra-polar portion of the nerve, and that the curve of diminished excitability is represented by *f*, *e*, *c*; the lowest degree being at the anode, *f*, and the nerve gradually recovering its normal excitability towards *c*.

the constant current is applied, and it will then be found that if the direction of this be as in Fig. 201, either a much weaker stimulus applied at *d* will produce contraction in the muscle, or the same stimulus will produce a much

Fig. 203.

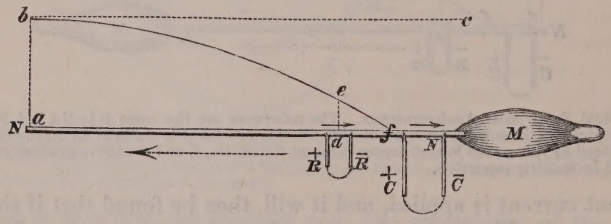


Extra-polar Centrifugal Katelectrotonus. The increase in the excitability of the nerve is shown by the curve, *g*, *e*, *c*, to be greatest in the vicinity of the kathode of the polarizing current, c, c.

more vigorous contraction, in either case showing that the excitability of the nerve has been increased. This is expressed by the curve *b*, *e*, *g*. If an electrical stimulus is employed, the current should be passed in the direction indicated, as in that case it would tend to reduce the influence of the kathode of c c, and by so much render the results obtained more striking. This constitutes Pflüger's extra-polar centripetal katelectrotonus. By a similar mode of proceeding, the excitability of the nerve behind the ascending current, or in the myopolar portion, which is under the influence of the positive pole of the constant current, c c, can, as by the curve *f*, *e*, *c* in Fig. 202, be shown to be remarkably diminished. This constitutes Pflüger's extra-polar centrifugal anelectrotonus. The curve *g*, *e*, *c*, in Fig. 203 shows the variation in the excitability in the myopolar portion of the nerve, when the Negative pole is next the muscle. Lastly, Fig. 204 shows the condition of excitability in the nerve

in centripetal extra-polar anelectrotonus. Pflüger found that in all these cases the strength of the polarizing current was of great importance, and that within certain limits the increase of excitability near the kathode, and the decrease near the anode, augmented; but that, if these limits be passed, and currents of much greater strength than usual were employed, the phenomena were less marked, and at length failed altogether to occur. From an examination of the curved lines in the preceding figures, it will also be seen that the excitability of the nerve varies with the distance of the part examined from the electrode, the increase or diminution being always greatest at the kathode and anode respectively, whilst the effect diminishes as these are receded from. There is one other circumstance that affects the excitability of the nerve—namely, the length of the intra-polar portion; and it would appear the longer this is, the greater is the extent and degree of the excitability of the nerve

FIG. 204.



Centripetal Extra-polar Anelectrotonus. Here, as indicated by the curve, *b*, *e*, *f*, the excitability of the nerve falls as the positive pole or anode of the polarizing current is approximated.

around the kathode. As regards time, the state of increased excitability always attains its full intensity with great rapidity. Thus much for the variations of excitability in a nerve rendered electrotonic.

433. The increase of electro-motive power that occurs in the vicinity of the positive pole, and the depression in that of the negative, has already been noticed. Another alteration effected in the nerve by the induction of the electrotonic state, is a variation in the velocity with which it will conduct impressions; this, according to V. Bezold, being invariably diminished. Dr. Rutherford, however,* finds that if currents of medium strength instead of the strong ones employed by V. Bezold be used, the negative pole quickens the rate at which the nervous influence is transmitted, whilst the positive pole retards it. As the general result of these researches, it appears then that the conditions present in a nerve, through a portion of which a closed continuous current is passing, and which is, therefore, in a state of electrotonus, are such that at the anode or positive pole of the current there is an exaltation of the intensity of the ordinary nerve-current (positive phase), and depression of the excitability (anelectrotonus), and of the conductivity or velocity of transmission of impressions. On the contrary, at the kathode there is constantly a depression of the intensity of the ordinary nerve-current (negative phase), and coincident exaltation of the excitability (katelectrotonus) and of the conductivity.†

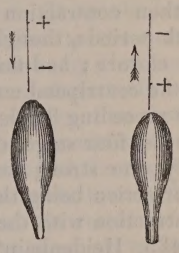
434. From the foregoing observations it will be intelligible that the action of electrical currents applied to nerves in producing muscular contraction is

* Humphry and Turner's "Journal of Anat. and Phys.," vol. ii. 1868, p. 95.

† A very different explanation of the phenomena of electrotonus, founded on chemical considerations, has been suggested by Hermann (see his "Untersuchungen," published at Berlin in 1867); but his views have been vigorously assailed in an able paper by Du Bois-Reymond, in the "Berichte der Berlin. Akadem.," 1867, p. 597.

liable to many variations, and that numerous circumstances must be taken into consideration before an explanation can be given of any particular phenomenon. Thus it has long been well known that though contraction of a muscle usually occurs at the moment of opening and closing a current of electricity transmitted through its motor nerve, yet that this is not constant, the contraction failing sometimes at the moment of closing and sometimes at the moment of opening the current. The singularity of this phenomenon has attracted the attention of many observers;* and it is now ascertained that the effects produced upon the muscle are dependent—1st, upon the direction of the electrical current passed through the nerve, whether centrifugal—*i.e.*, from the origin to the periphery of the nerve (Fig. 205), or centripetal—*i.e.*, from the periphery towards the origin (Fig. 206); 2ndly, upon the state of excitability of the nerve; and 3rdly, upon the strength of the current. Ritter and Nobili, in whose observations the strength of the current was disregarded, endeavoured to show that a definite succession of results followed the application of the electrical stimulus, according to the direction and the excitability of the nerve. Ritter, operating on Frogs, the excitability of whose nerves departed slowly after death or excision, was able to distinguish six stages; whilst Nobili, operating in the warmer climate of Italy, could distinguish only four. The following tabular arrangement taken from Funke will show the relations of the contraction of the muscle to the degree of excitability remaining in the nerve, and to the direction of the current:—

Fig. 205. Fig. 206.



Ritter and Nobili's Law of Contraction.

C *indicates closure of the current;* O *indicates opening of the current, or breaking contact.*

Grade of Excitability of the Nerve.	Ascending or Centripetal Current.	Descending or Centrifugal Current.
I. (Ritter)	C, Contraction O, Rest	C, Rest. O, Contraction.
II. (Ritter)	C, Contraction O, Slight Contraction	C, Slight Contraction. O, Contraction.
III. (Ritter) I. (Nobili)	C, Contraction O, Contraction	C, Contraction. O, Contraction.
IV. (Ritter) II. (Nobili)	C, Weak Contraction (Ritter) / Rest (Nobili) O, Contraction	C, Contraction. O, Slight Contraction.
V. (Ritter) III. (Nobili)	C, Rest O, Contraction	C, Contraction. O, Rest.
VI. (Ritter) IV. (Nobili)	C, Rest O, Rest	C, Slight Contraction. O, Rest.

From this Table it is apparent that in the highest grade of excitability of the nerve, the centripetal current induces contraction only on closure of the current,

* As of Ritter and Nobili, Matteucci, Du Bois-Reymond, Eckhard, and Pflüger.

none occurring on opening it. Contraction on opening the current first happens in the second stage—*i.e.*, when the excitability of the nerve is somewhat diminished, and is then only feeble. In the 3rd stage of excitability of Ritter, the 1st of Nobili, the vigour of the opening and closing contraction is about equal. In the 4th grade, the closing contraction is weak, the opening strong. In the 5th stage, there is no contraction on closure, but it occurs on opening the current; whilst in the 6th and last stage no contraction follows either the closure or the opening of the current. For the descending or centrifugal current, the phenomena present themselves in an inverse order,—in the first or highest stage of excitability, there is contraction only on opening the current—then weak contraction on closure, as well as contraction on opening—then contraction of equal strength at both periods—then contraction at both periods, though weaker on opening the current—then contraction only on closure; and finally, in which respect it differs slightly from the effects of the centripetal current, weak contraction on closure of the current. From the preceding Table, the statement of Nobili, who only experimented during the last four stages of irritability, becomes intelligible, that there is essentially only one strong contraction for each direction of the current; an opening contraction being the most marked with the centripetal current, and a closing contraction with the centrifugal current.

435. Heidenhain* and Pflüger,† following up this train of research, showed that in freshly-prepared nerves, whose *excitability was therefore of the highest grade*, the law of contraction was dependent upon the strength of the current; and the phenomena have been thus formularized by Pflüger:—

Strength of Current.	Direction of Current.	
	Centripetal.	Centrifugal.
Weak . . . {	C, Contraction . . O, Rest	C, Contraction. O, Rest.
Moderate . . {	C, Contraction . . O, Contraction . .	C, Contraction. O, Contraction.
Strong . . . {	C, Rest . . . . . . O, Contraction . .	C, Contraction. O, Weak Contraction.

Thus beginning with currents so feeble that no contraction is induced either on making or on breaking contact in very excitable nerves, Pflüger found that on passing a slightly stronger, but still weak current, in a centripetal direction, contraction first occurs on closure, but none on opening. With currents of moderate strength, contraction occurs both on closing and opening the current; and lastly, if the current exceeds a certain strength, no contraction occurs on closing, though it is well marked on opening the current. If the same experiments are repeated with the centrifugal current, we obtain with the weakest current contraction on closure alone (exceptionally also on opening); with moderately strong currents, contraction both on opening and closure; and with strong currents, the closing contraction preponderates with centrifugal currents, and the opening contraction with centripetal. As regards the reactions of sensory nerves, it is maintained by Pflüger that the effects

* Heidenhain in "Archiv f. Phys. Heilk," 1857, p. 442.

† Pflüger, "Archiv f. Path. Anat.," Band xiii.; and "Untersuchungen über d. Physiologie des Electrotonus," Berlin, 1859.

produced by electrical stimulation are dependent upon the force of the current, except that, as might be expected from the direction in which they ordinarily conduct their impressions a kind of inverse relation exists.

436. Those who hold with Hermann and Onimus, with whom Ranke is to some extent in accord, that many of the electric phenomena presented by nerve and muscle are dependent upon chemical action, extend this view to the explanation of the different conditions of electrotonus. Onimus,* for example, refers to an experiment made by Matteucci, which consists in covering a platinum wire a yard in length with tow. The wire is dipped in salt, and arranged as in the experiment for showing electrotonus. On passing a current of electricity through a given portion of it, a strong electrotonic condition is established, even at a distance of eighteen inches or more. It would hence appear that the electrotonic state is not one that is peculiar to the nerves, and this part of the subject has been carefully worked over by Hermann.† They further offer a very simple explanation of the anelectrotonic and katelectrotonic zones of Pflüger. They contend that the passage of an electric current through a nerve is attended by an electrolytic action resulting in the formation of acids around the positive pole and of alkali around the negative, which is sufficient to explain all the phenomena, since acids lower whilst alkalies exalt the excitability of the nerve. Pflüger, from the results of his experiments, laid down the following law :—A certain length of nerve being given, this is excited by the supervention of katelectrotonus and by the disappearance of anelectrotonus; but it is not excited by the disappearance of katelectrotonus nor by the supervention of anelectrotonus. This law has been slightly modified by Cyon, who formulates it as follows :—A nerve is excited when its molecules pass from their ordinary state to one of greater mobility (katelectrotonus), or when they pass from a state of less mobility (anelectrotonus) to the ordinary state. The nerves do not, on the contrary, experience any excitation, either when they pass from their ordinary to a state of less mobility (anelectrotonus) or on their passage from a state of greater mobility (katelectrotonus) to their ordinary state.‡ Onimus maintains that the practical value of these facts rests in remembering two well-established points—First, that the descending or direct current is that which acts most energetically on motor nerves, or, in other words, the descending current is that which most strongly calls forth muscular contraction; and secondly, that every current when applied to a nerve determines a current in the opposite direction at the moment of its cessation. Thus each time that a nerve is electrified with an ascending current a descending current is developed at the moment of breaking in the interior of the nerves, and contrariwise at the moment when a descending current is broken an ascending current is formed. In accordance with this, Onimus gives the subjoined table, obtained by electrifying nerves without the direct application of the poles to the nerve, which he contends interferes with the results, since it causes local electrolytic action. It will be seen to resemble the scheme given by Nobili.

		Descending Current.	Ascending Current.
1. Period	Closure	Contraction	Contraction.
	Opening	Contraction	Contraction.
2. Period	Closure	Contraction	Feeble Contraction.
	Opening	Feeble Contraction	Contraction.
3. Period	Closure	Contraction	O
	Opening	O	Contraction.
4. Period	Closure	Contraction	O
	Opening	O	Feeble Contraction.
5. Period	Closure	O	O
	Opening	O	Feeble Contraction.

Thus, in the first period, the excitability of the nerve being undiminished, contraction of the muscle takes place as soon as the molecular state of the nerve undergoes alteration, which occurs both at the moment of closure and of breaking of the current; but by degrees, as the excitability of the nerve diminishes, contraction takes place only on the closure of the descending current, and on the opening of the ascending current. But the breaking of the ascending current is equivalent to the formation of a descending current, so that as the third period is reached the muscle only contracts with a descending current. In the same way, at the moment of breaking a descending current an ascending current is formed which remains without action on the muscles like the ascending current of the battery. At the fourth period the ascending current only gives the contraction of opening when the current has been applied for some time, for then the (descending) polar current becomes more energetic. At the fifth period, when the current of the battery no longer gives any contraction, this may still be sometimes obtained by the polar current. Thus Onimus maintains that by taking into consideration the formation of a polarizing current, and the greater action of the descending current, all the phenomena of Pflüger's alternations admit of ready explanation.* Grützner's† observations and experiments have led him to the conclusion that centripetal nerve fibres are stimulated by heat and by the constant current, apart from the opening and closing of the current, but of the centrifugal fibres only those are stimulated by the constant current which dilate the cutaneous vessels. The secretory and motor nerves are not persistently affected by the constant current.‡

2. *Of the Spinal Cord and Medulla Oblongata;—their Structure and Actions.*

437. In our more detailed consideration of the functions of the several divisions of the Nervous System, it is desirable, for several reasons, to com-

* Dr. Radcliffe, who has paid much attention to the subject of electrotonus, notes various facts which make it difficult to believe that the electrotonic movements of the needle have to do, as Du Bois-Reymond supposes, with changes in the nerve-current, produced by the action of the electrotonizing current upon the nerve. His conclusions are contained in his work entitled "Dynamics of Nerve and Muscle," post 8vo, Macmillan and Co., 1871; and "Vital Motion a mode of Physical Motion."

† Pflüger's "Archiv," 1878, p. 249.

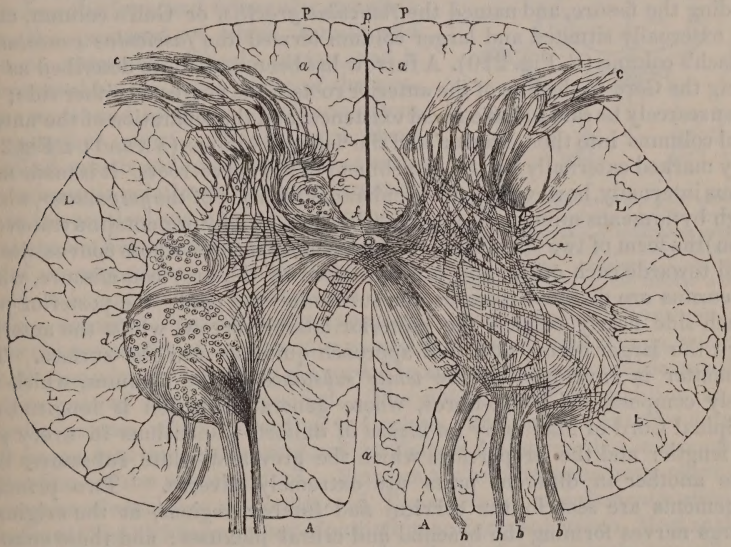
mence with the *Cranio-Spinal Axis;* which, as already pointed out, may be considered as constituting the fundamental portion of this apparatus. The entire Axis is divided into its Cranial and its Spinal portions, the passage of the Cord through the 'foramen magnum' of the occipital bone being considered to mark the boundary between them; and although the separation of the Medulla Spinalis from the Medulla Oblongata, which is thus established, is in itself purely artificial, yet it will be found to correspond completely with the natural division founded on their respective physiological attributes.

438. The *Spinal Cord*,* which extends from the margin of the foramen magnum to the first or second lumbar vertebra, and which is prolonged as the *filum terminale*† to the extremity of the sacral canal, is almost completely

FIG. 207.



Transverse section of *Spinal Cord*, through the middle of the lumbar enlargement, showing on the right side the course of the nerve-roots, and on the left the position of the principal tracts of vesicular matter:—A, A, anterior columns; P, P, posterior columns; L, L, lateral columns; *a*, anterior median fissure; *p*, posterior median fissure; *b*, *b*, *b*, *b*, anterior roots of spinal nerves; *c*, *c*, posterior roots; *d*, *d*, tracts of vesicular matter in anterior column; *e*, tracts of vesicular matter in posterior column, termed by Jacubowitsch the "sympathetic" column or tract; *f*, central canal, surrounded by the grey commissure; *g*, substantia gelatinosa of Rolando.

divided by the *anterior* and *posterior median fissures* (Fig. 207, *a*,*p*), into two lateral and symmetrical halves. The 'anterior median fissure' (*a*) is more distinct than the posterior, being wider at the surface; but it only penetrates to about one-third of the thickness of the Cord, its depth increasing, however, towards its lower part. The sides of the 'posterior median fissure' (*p*), on the other hand, are in closer approximation; but the division commonly

* The sketch given in the text of the Anatomy of the Spinal Cord, is chiefly derived from the statements of Prof. Kölliker, in his "Mikroskopische Anatomie" (Band ii. §§ 115, 116), and of Mr. J. L. Clarke in the "Philosophical Transactions," 1851, 1853, and 1859; but Gerlach gives an excellent account of it in Stricker's "Hum. and Comp. Histology," Syd. Soc. Transl., vol. ii. p. 327.

† The structure of the 'filum terminale' is in every respect essentially the same as that of the proper Spinal Cord, save that no nerve-roots are connected with it.

extends to about half the thickness of the cord, being deeper towards its upper than towards its lower end. The two halves, therefore, are only united by a commissural band, which occupies the central part of the cord; and this is traversed by the 'Spinal canal' (*f*), which is continued downwards from the fourth ventricle, is about 1-100th of an inch in diameter, and, according to Lockhart Clarke, is lined with a layer of columnar ciliated cells, whose attached extremities taper into delicate fibres, and become continuous with the fibres of the connective tissue of the white columns.—At a little distance from either side of the posterior median fissure, and corresponding with the line of attachment of the posterior roots of the nerves, is the *posterior lateral furrow;* a shallow, longitudinal depression, which marks out the 'posterior columns' of the Cord (P, P) as distinct from the 'antero-lateral columns.' In the cervical and dorsal regions the posterior column is itself divided into a fasciculus (*c*, Fig. 210) bounding the fissure, and named the *funiculus gracilis*, or Goll's column, and a more externally situated and larger column termed the *fasciculus cuneatus*, or Burdach's column (*d*, Fig. 210). A furrow has been sometimes described as traversing the Cord in the line of the anterior roots of the nerves on either side; but this can scarcely be said to have a real existence; and the separation of the 'antero-lateral columns' into the 'anterior' and the 'lateral' columns (A A and L L Fig. 207) is only marked externally by the attachment of the nerve-roots. It is made more obvious internally, however, by the peculiar distribution of the *grey matter*, which, though by no means uniform throughout the Cord, usually presents (in a transverse section) the form of two somewhat crescent-shaped masses, whose convexities are turned towards each other, and are connected by the grey commissure, whilst their cornua are directed towards the surface of the cord; the posterior peak on each side nearly reaches the posterior lateral furrow, whilst the anterior, though the larger cornu, does not approach quite so near the surface. The grey matter is enveloped by the *white substance* of the columns, which are entirely composed of nerve-fibres, whose general direction is longitudinal. The Spinal Cord of Man is by no means of uniform dimensions in every part of its length: and the proportions which the grey and white substances bear to one another in different parts are extremely diverse. Two principal enlargements are seen in the cervical and lumbar regions, at the origins of the large nerves forming the brachial and crural plexuses; and these enlargements are chiefly due to an increase of the *grey* substance, which is comparatively deficient in the intervals. On the other hand, there is a regularly-progressive increase in the *white* substance, as we proceed from the lower to the higher portion of the cord; and this fact of itself serves to indicate the probability, that the longitudinal columns serve (as formerly supposed) to establish a direct connection between the Encephalic centres and the ganglionic cells from which the roots of the Spinal nerves arise or with these roots themselves.

439. The *grey matter* or *vesicular substance* of the Spinal Cord, which is best seen in transverse section (Figs. 207 and 208), is by no means uniform in its texture throughout. Its *anterior cornua* (*d*, Fig. 207 and *l*, Fig. 208), which are thicker and shorter than the posterior, are of a uniform grey colour; and they consist of large, well-developed nerve-cells, which usually present many radiating processes, one of which generally passes into the anterior root of the nearest spinal nerve; whilst another ascends on its own side, and others form communications either with adjoining cells or with those in the horn, or on the opposite side of the Cord. The cells of the anterior horn connected together in this way form groups which may reasonably be supposed to constitute centres for the numerous fibres distributed to each muscle, so that an impulse of the will or other stimulus acting upon one of the cells may

excite the whole to equal and consentaneous action, and thus abolish the necessity that would otherwise exist for every muscular fibre to possess its own motor nerve direct from the brain. The central portion, which contains the canal, and which also forms the commissure, has a similar composition; but the cells are smaller, though still having long branching radiations; and the fibres are extremely fine, their tubularity being often indistinguishable. The *posterior cornua* (Fig. 208 *g*, *h*, *i*, *j*) are longer and narrower than the anterior, and each is divided into a caput and a cervix cornu.* The caput or bulbous extremity of the horn consists of an outer and comparatively transparent gelatinous portion, named the *substantia gelatinosa* of Rolando, similar in structure to the grey substance surrounding the central canal. It contains numerous fusiform and triangular ganglion cells, the processes of which ramify and form an extremely delicate plexus, and it is traversed by the nerve fibres of the posterior roots, and by fibres which arise from the ganglion cells. Mingled with these are blood-vessels and some connective tissue. The substantia gelatinosa attains its greatest size in the cervical and lumbar enlargement, that is, at the points, where the largest number of sensory nerves enter the cord. By some† it is regarded as a tissue of a supporting nature. The *substantia spongiosa* forms the remainder of the posterior as well as of the anterior cornua, and constitutes the most important part of the cord. It contains numerous multicaudate cells, the processes of which are ramified. The cells give off in addition an axis-cylinder process, which, according to Gerlach, runs into the anterior cornu and then passes into the *anterior* root, whilst Deiters maintains that it is continuous with a fibre of the *posterior* root. Between the cells are numerous nerve fibres, the course of which has not been traced. The *median or commissural portion* of the spinal cord (Fig. 205) is composed of both white and grey substance. Most anteriorly and forming the bottom of the anterior longitudinal fissure is the anterior white commissure, which is chiefly composed of decussating fibres. Some of these are derived from the anterior columns, and from the anterior roots of the spinal nerves of the opposite half of the cord, which probably ascend in the antero-lateral columns, or join the median motor ganglion cells of the opposite side, others are commissural between the anterior cornua, and others again appear to come from the posterior roots. Besides these the anterior white commissure contains some longitudinal fibres. Behind the anterior white commissure is the anterior grey commissure (*h*), and the broader posterior grey commissure (*g*), which forms the bottom of the posterior longitudinal sulcus, with the central canal and surrounding gelatinous substance between them. The fibres forming the posterior grey commissure pursue a course that seems to show they are connected with the posterior roots of the spinal nerves, and with the cervix cornu posterioris of the opposite side. There is therefore here also a decussation of fibres. Situated a little in front of the exact centre is the central canal (Figs. 208 *m*, 209 *c*). This is a minute passage, the cavity of which in the adult

* See Lockhart Clarke, "Phil. Trans.," 1858, p. 249. Gerlach, Art. 'Spinal Cord,' in Stricker's "Human and Comp. Histology," vol. ii. p. 355, 1872.

† Schwalbe, "Lehrbuch der Neurologie," 1880, p. 347.

is usually obliterated with cells, but which in childhood is lined by a layer of ciliated columnar cells, the attached extremities of which, named the ependyma fibres, dip into a layer of gelatinous tissue resembling the substantia gelatinosa of Rolando. The major part of this substance is finely granular, the dots being probably the cut ends of fibrils, and besides the radiating fibres of the columnar central cells, some concentric fibres may be seen, with a few scattered nerve fibres and stellate cells. A remarkable column of ganglionic cells, constituting the inner and anterior part of the Cervix cornu (*j*, Fig. 208), and extending from the lower part of the cord to the middle of the cervical enlargement where it terminates, has been described by Clarke under the term of the *posterior vesicular column.** The point of junction of the anterior and posterior cornua (*k*) is termed by the same observer the *tractus intermedio-lateralis*. It extends from the upper roots of the eighth cervical nerves to the lowest part of the dorsal region, but is most prominent about the first and second dorsal nerves. The posterior vesicular columns, on the other hand, are largest at the lowest part of the dorsal region. The delicately fibrillated and granular nucleated substance which intervenes between the axis-cylinders of the grey substance of the spinal cord and forms the greater part of it, termed 'neuroglia' by Virchow, 'reticulum' by Kölliker, 'granular basement substance' by Henle, and 'spongy substance' by Schultze, is believed by Henle,† Robin,‡ and others to be quite distinct from connective tissue, not only in function, but in miscroscopical characters and in chemical reactions.§ It is chiefly found in the grey substance of the nervous centres, and it immediately surrounds the central canal of the cord.‖ It is an almost transparent material of grey colour, and of finely granular aspect¶ like the matrix of hyaline cartilage, with little clumps of cytoid bodies (myelocytes) scattered through it, which seem to be in connection with the cells lining the central canal and with the pia mater. Pervading every part of the neuroglia of the grey substance of the cord, except that lying in immediate proximity to the central canal, is a close plexus of extremely-fine fibres, chiefly derived from the processes of the nerve cells just described. The blood-vessels of the central parts of the nervous system are surrounded by a loose sheath, between which and the proper external coat

lymph corpuscles are perceptible.* These spaces His considers to represent the lymphatic system of these parts, which are otherwise destitute of this system of vessels.

440. The connection of the Nerve-roots of the Spinal Nerves with the several components of the Cord, and the course of the fibres after entering it, may be made out partly by means of *sections*, and partly by following the course of individual fibres by ordinary microscopical dissection.† The following is an outline of the information which may thus be gained from a comparison of transverse and longitudinal sections (Fig. 207 *et seq.*).—The bundles that form the Posterior roots (Fig. 205, *c*, *c*) consist of three sets, which differ from each other partly in direction, and partly in the size of their component filaments. The *first* set (which are more numerous in the upper part of the Cord), enter the posterior columns horizontally; and then, taking a longitudinal direction *down* the Cord, send fibres into the anterior grey substance, of which some bend upwards, and others downwards; part apparently becoming continuous with fibres of the anterior roots; whilst another part lose themselves among the fibres of the anterior columns, in which they may either proceed continuously to the head, or may pass along for a limited distance only, to emerge in the nerve-roots of some other segment. The *second* set of bundles also traverse the posterior columns horizontally and obliquely inwards; their further course may be best traced in a transverse section (Fig. 207). These fasciculi, which are composed of remarkably fine and delicate fibres, interlace so as to form with each other an intricate plexus; and from this, straight and distinct bundles enter the posterior cornua along their whole breadth, crossing the 'substantia gelatinosa' both obliquely and at right angles. Having thus entered the vesicular substance of the Cord, some of the fibres become connected with multipolar ganglionic cells; others, after traversing it, emerge from it again, into either the posterior columns, or the posterior portion of the lateral columns; others pass towards the transverse commissure, through which they seem to make their way to the posterior lateral columns of the opposite side; and others, again, form a fine network, which extends towards the anterior cornua. Of the fibres of a *third* set, a part seem to become directly continuous with the fibres of the posterior columns; the larger proportion of them, however, cross these columns obliquely upwards, and enter the grey substance at different points; after passing into which, they can no longer be clearly followed, although some of them appear to form loops and then return to the white columns.—The fasciculi of fibres which constitute the Anterior roots (Fig. 207), on the other hand, traverse the anterior columns of the Cord nearly horizontally, and in straight and distinct bundles, which do not interlace with each other until they reach the anterior cornua of the grey substance; on entering this, they break up into smaller bundles and separate fibres, which diverge in various directions, but, in the lumbar and cervical enlargements, where their course can be most distinctly followed, run in three main directions, laterally, directly backward, and towards the middle line; in each of these groups many fibres may be found which unite with the large multipolar ganglionic cells of the anterior horns of the grey substance; whilst some are believed to pass out again into the anterior, and others into the lateral columns of the same side, without entering any ganglion cell, but ultimately crossing to the opposite side at the decussation of

* His in Siebold and Kölliker's, "Zeitschrift," Band xv. 1865, p. 127.

† J. L. Clarke succeeded, by the adoption of a peculiar method of preparation (for which see "Phil. Trans.," 1868, p. 321), in making sections of considerable thickness sufficiently transparent to allow the course of the fibres and the contour of the nerve-cells and their prolongations, to be distinctly made out.

the pyramids. The statement that the fibres are not connected with any cell requires, however, confirmation. Other fibres, again, pass towards the anterior part of the commissure, in which they cross over to the opposite side, entering into connection with the cells of the anterior cornu, or ascending in its anterior and lateral columns; a considerable number plunge into the central substance of the grey cornu, and of these some become longitudinal, passing equally upwards and downwards, whilst others seem to traverse it horizontally, so as to come into relation (not improbably, through the intermediation of ganglion cells, into actual continuity) with the posterior roots.*

441. Thus we see that there are two very distinct courses pursued by the root-fibres of the Spinal Nerves, in the substance of the Cord; the first *transverse*, the second *longitudinal*. The fibres belonging to the former category traverse the Cord horizontally or obliquely, and appear to be connected with the other set of roots connected with the same segment, either on its own or on the opposite side of the median fissure. Of those belonging to the latter, a small part appears to connect the posterior roots directly with the posterior columns, without passing into the vesicular substance; but the remainder of those belonging to the posterior roots first enter the grey matter of the Cord, and then emerge from it either into the posterior column, or into the posterior part of the lateral column of their own or of the opposite half of the Cord; and, in like manner, all the longitudinal fibres belonging to the anterior roots first enter the vesicular substance, and either terminate in the ganglionic cells in the anterior horn or re-enter the anterior column, or the anterior part of the lateral column, of the same or of the opposite side. The longitudinal fibres of the Cord taken collectively form a series of fasciculi or columns which probably possess definite functions, since, in the process of development, certain fasciculi obtain their myelin investment at different periods, whilst, on section of the whole Cord, certain fasciculi alone degenerate above and below the section, and, in cases of disease of certain parts of the brain, particular fasciculi alone atrophy. An attempt to represent the position of these fasciculi has been made by Flechsig (see the accompanying wood-cut Fig. 210). The anterior column is divided into the *pyramidal* fasciculus (*a*), which immediately

* Those who are desirous of pursuing the structure of the Spinal Cord in more detail than can possibly be given in a general survey like the present, are referred to the important work published by Stilling in 1856, entitled "Neue Untersuchungen über den Bau des Rückenmarks," in 3 parts, with an atlas; also to the "Untersuch. über den feineren Bau des Central Nerven-system des Menschen," by J. v. Lenhossek, Wien, 1855; to the researches of Bidder and Kupffer, "Ueber die Textur des Ruckenmarks," Leipzig, 1857; to the valuable papers in the "Philosophical Transactions" for 1851, 1853, 1858, part i. p. 231, 1859, part i. p. 437, by J. Lockhart Clarke; to the Translation by the Sydenham Society of the treatise of Schröder v. d. Kolk, 1859; and to the essays of Dr. C. Frommann, "Untersuch. üb. die Norm. u. Path. Anat. des Ruckenmarks," Jena, 1864, 4 plates; the work of J. Luys, "Recherches sur le Système Nerveux Cérébro-spinal," Paris, 1865; Gerlach, in Stricker's "Human and Comp. Histology," Syd. Soc. Trans., 1872 p. 327; Pick, "Centralblatt," 1878, p. 20.

bound the anterior fissure, and the more externally situated proper or *fundamental* fasciculus. The posterior column contains the *fasciculus gracilis* of Goll (*c*) and the *fasciculus cuneatus* of Burdach (*d*). The lateral columns are composed of the anterior (*e*) and the lateral mixed fasciculi (*f*), the pyramidal fasciculus (*g*), and, lastly, (*h*,) the lateral cerebellar fasciculus. Of these, *a* and *g* are the fasciculi which contain all the connecting fibres between the grey substance of the Cord and the ganglion of the pes cerebri, which pass onwards to the central convolutions of the cortex of the Cerebrum; *h*, composed of coarse fibres, connects Clark's column in the grey substance of the Cord with the Cerebellum; *b*, *e*, and *f* are composed of fibres connecting the reflectorial centres in the grey substance of the Cord and in the medulla oblongata, and also the fibres which constitute the upward prolongations of the anterior roots, and which by degrees enter the grey matter of the Cord; *c* is composed of fibres which connect the posterior roots of the spinal nerves with the grey nuclei of the *funiculi graciles* of the medulla oblongata; *d* is composed of fibres connecting the posterior roots with the grey matter, as well as fibres connecting both these with the retiform nucleus in the medulla oblongata. The fasciculi *a*, *g*, *h*, and perhaps also *c*, present a progressive increase in sectional area in passing from below upwards, which is in accordance with the view that they connect intra-cranial central regions with ganglionic centres distributed in the grey substance of the Cord. The fasciculi *h*, *d*, and *e* vary in size in different parts of the Cord, in correspondence with the number and size of the nerve-roots entering them; hence we may conclude that these fasciculi contain fibres which connect different parts of the Cord with each other and with the medulla oblongata, but do not pass up directly to the higher parts of the cerebrum.—A very remarkable confirmation, too, has been afforded to the doctrine of the constitution of the Spinal Cord here advocated by the Pathological researches of Dr. Ludwig Turck;* who has shown that certain lesions of the Encephalon produce a degeneration of nerve-tissue in particular tracts, which may be traced continuously down the Spinal Cord, usually in the *anterior* column of the side affected, and in the *lateral* column of the opposite side; whilst, on the other hand, local lesions of the Spinal Cord, as from caries of the vertebræ, or from the pressure of tumours, produce a like degeneration in certain tracts of the posterior columns, and sometimes also of the lateral columns, ascending towards the Encephalon. Thus it appears that the *posterior* fasciculi are liable to this secondary degeneration in the *centripetal* direction only, and the *anterior* in the *centrifugal* direction only; the degeneration taking place, in each case, in the direction in which they ordinarily transmit nerve-force. The mixed endowments of the *lateral* columns are also indicated by these phenomena; and Schiferdecker found that these fasciculi atrophied in the inferior or distal part of a divided Spinal Cord. Hence it seems to follow that their nutritive centre must lie in the cerebrum. The anterior roots of the spinal nerves have their nutritive centre in the grey matter of the Spinal Cord. The fasciculi *c* and *h* atrophy in the upper or proximal part of the Cord after its section; the latter probably have their nutritive centre in the ganglia of Clarke's column, and the former in the spinal ganglia of the posterior roots. Those fibres which do not atrophy after section of the Cord are probably commissural fibres from one part of the Cord to

* See his Memoir 'Ueber secondäre Erkrankung einzelner Rückensmarksstränge und ihrer Fortsetzungen zum Gehirne,' in "Denkschriften der Kaiserlichen Akademie der Wissenschaften," Wien, 1851; also "Zeitschrift der Gesell. der Aertze zu Wien," Band ix. Heft 10.

† The materials of this section have been chiefly taken from Landois, "Physiologie," 1880, pp. 702, 703.

another. The pyramidal fasciculi and the pyramids themselves are absent in cases of congenital absence of the brain.* In regard to the period of development of the several fasciculi, Flechsig states that the first to form are the nerve-roots, or the paths for nervous influence, extending between the periphery and the central grey substance of the Cord. Then those commissural fibres originate which connect different parts of the Cord with each other. Then those fibres which extend from the grey substance of the Cord to the cerebellum and to the tegmentum of the pedunculus cerebri; and, finally, those fibres which constitute a connection between the grey substance of the Cord and the pes of the pedunculus cerebri, and perhaps with the cortex of the brain itself.

442. The observations of Clarke show clearly that some of the fibres of the anterior roots never become longitudinal, and these, accordingly, have no other ganglionic centre than the vesicular substance of the segment of the Cord with which they come into immediate relation; they also render it extremely probable that many of the longitudinal fibres of both roots pass continuously upwards to the Encephalon, most of them after traversing the grey nucleus, but some of those of the posterior roots without even entering the vesicular substance, so that *these* cannot have their ganglionic centre in the Cord at all. If the latter be among the fibres which pass up through the Posterior Pyramids into the sensory tract of the Crura Cerebri, their true ganglionic centres are the Thalami Optici. That such is the real arrangement, is very strongly indicated by the analogous conformation of the gangliated cord of Arthropoda; for it may be stated with tolerable certainty, that some of the root-fibres of their nerves pass along the purely-fibrous tract of that cord (which is far more readily separated from the vesicular than it can be in Vertebrata) directly to the cephalic ganglia, which they thus bring into direct communication with all the nerve-trunks connected with the gangliated cord; but that others, also becoming longitudinal, and running along those portions of the cord which intervene between and connect the ganglia of the different segments, pass into the nerve-trunks that emerge from ganglia at a distance of one, two, three, or more segments above or below; whilst a large proportion of the root-fibres have their ganglionic centres in the ganglia which they respectively enter; and, after coming into relation with its vesicular substance, pass out again, either on the same or on the opposite side of the median plane.* Now the purely-fibrous tract of the ventral cord of the Arthropoda terminates in the Cephalic ganglia, which are homologous, as already remarked (§ 404, IV.), not with the whole Encephalon of Vertebrata, but with their 'sensory ganglia' alone; and thus analogy would lead us to suppose, that the fibrous strands of the Spinal Cord do *not* pass on continuously to the *Cerebrum*, but really extend no further upwards than the Corpora Striata, Thalami Optici, and the other ganglionic centres in connection with them which lie along the floor of the cranial cavity. This view will be hereafter shown (Sect. 3) to be in harmony with anatomical and physiological facts, which indicate that the Cerebrum only receives its impulses to action through the medium of the Sensory Ganglia, and that it reacts upon the muscular apparatus only through the same channel. That some of the afferent fibres of the spinal nerves should ascend continuously upwards to the ganglia of tactile sense, in Man and other Vertebrata, as well as in Arthropoda, would seem a legitimate deduction from the fact that such continuity obviously exists between the olfactory, visual, and auditory nerves, and *their* respective ganglionic

* See "Princ. of Comp. Phys.," § 648.—The important facts here referred to have been chiefly substantiated by the researches of Mr. Newport and M. Günther.

centres, no intermediate apparatus of vesicular matter being interposed in their course; and, as we have seen (§ 439), the existence of such a continuity in regard to a part of the fibres of the posterior roots of the nerves, is made extremely probable by the researches of J. L. Clarke.

443. We are not required, however, by the adoption of this view of the constitution of the Spinal Cord to regard its Cephalic fibres as of a *different order* from those which pass from one of its own segments to another; for, considering the whole of the Cranio-Spinal axis as *one series of centres*, receiving the terminations of all the nerves, its longitudinal fibres are equally *commissural*, whether they establish the connection between the nerve-roots and vesicular matter of two adjacent segments, or whether they bring into the same structural relation the parts which are furthest removed in position. And thus we may regard all impressions upon the afferent nerves as first operating upon it (affecting the consciousness, or not, according as they reach the Sensory Ganglia, or are arrested in their progress thither); and all motor impulses, whether purely-reflex, or originating in volitional direction or emotional excitement, as issuing immediately from it through the motor trunks.—If such be the case, it does not seem at all improbable that there should be a difference in different tribes of animals, as to the proportion of fibres which have their centres in the Spinal Cord and in the Sensorial centres respectively; for in those whose ordinary movements of progression, &c., are independent of sensation, being performed through the reflex action of the spinal cord, it might be expected that the chief connection of the spinal nerves should be with its own ganglionic substance, and that the bulk of the fibrous columns should be composed of commissural fibres resembling those which intervene between the separate portions of the ganglionic tract of the ventral cord of Arthropods; whilst in like manner it might be anticipated that in man, so large a portion of whose movements are performed in obedience to a mental stimulus and under the guidance of sensation, the longitudinal strands should be chiefly composed of fibres that directly connect the sensorial centres with the roots of the spinal nerves. Such a difference would appear, from the comparative researches of MM. Volkmann and Kölliker, to exist between the structure of the Spinal Cord of the Horse and that of Man.

444. The *Medulla Oblongata*,* or cranial prolongation of the Spinal Cord, which brings it into connection with the Encephalic centres, is distinguished by the highly complex arrangement of its fibrous strands and of its nuclei of grey matter; and also by the peculiar distribution and endowments of the nerves connected with it. The anatomical boundaries usually assigned to it are the Pons Varolii above† and the Occipital foramen below; but these limits are purely artificial, and for physiological purposes the course of its fibres must be traced much higher. The part thus marked out has a bulb-like form, and presents, like the Cord of which it is the continuation, a posterior and an anterior median fissure. The former is deep and narrow at first, but suddenly widens out to form the space known as the *sinus rhomboidalis* or Fourth ventricle. The latter is wider and less deep; and its continuity with

* For good accounts of the anatomy of the Medulla Oblongata, see Dr. John Reid in "Edinb. Med. and Surg. Jour.," 1841; Mr L. Clarke in the "Phil. Trans.," 1858, vol. i., and 1868, Pt. i.; and Dr. John Dean, 8vo, 1863. Schröder v. d. Kolk, "Syd. Soc. Transl." Meynert, Art. 'Brain of Mammalia' in Stricker's "Hum. and Comp. Histology," Syd. Soc. Trans., vol. ii. 1872, p. 367. Henle, "Handbuch der Nervenlehre." Schwalbe, "Lehrbuch der Neurologie," 1880.

† From which it is separated laterally in animals by a broad band termed the Trapezium, but in man by a groove; the trapezium forming the posterior border of the Pons. See L. Clarke, "Proceed. Roy. Soc.," vol. xi. p. 360.

the anterior fissure of the Spinal Cord is interrupted by the decussation of the Anterior Pyramids, which is marked externally by the crossing of from three to five bundles of fibres from each side over to the other. This decussation may be considered as the physiological boundary between the Medulla Oblongata and the Spinal Cord. The surface of each lateral half is furrowed by grooves, which assist in marking out the several strands of nerve fibres that may be distinguished on either side. The vesicular substance is aggregated into several pairs of ganglionic nuclei which form extremely important nerve centres. The principal columns of the Medulla Oblongata on each side are—

Fig. 211.

Scrip.*, calamus scriptorius. Between *f g* and *p x* is the sulcus intermedius posterior; between *a p*, and *o c* is the sulcus intermedius anterior.

445. The *Anterior Pyramid*, or Funiculus Pyramidalis, which consists entirely of fibres, establishing a communication between the 'motor tract' (Fig. 212, *m t*) of the Crura Cerebri, and the anterior and antero-lateral columns of the Spinal Cord. Some of the fibres of this column are derived from the anterior column of the cord of their own side, others are derived from the anterior column of the opposite side, but by far the largest number are a continuation upwards of the fibres running in the posterior part of the lateral column of the opposite half of the cord, and their decussation is very apparent at the lower and front part of the Medulla Oblongata.* Some fibres have been traced by Clarke† into the posterior columns and posterior cornu of the cord. On reaching the pons, the anterior pyramids are concealed by the transverse fibres of that body, but may be traced into the peduncles of the cerebrum.—The *Olivary Funiculus* is composed of white fibres, and presents at its upper and median part a swelling named the *olive*, which encloses a large grey motor nucleus (Fig. 212, *o g*). The upward continuation of this funiculus divides, while passing through the Pons Varolii, into two bands, one of which proceeds upwards and forwards as a part of the 'motor tract' (*m t*) of the Crus Cerebri, whilst the other (*o*) proceeds upwards and backwards to reach the Corpora Quadrigemina (c, d). The Olivary columns are continuous inferiorly with the antero-lateral columns of the Spinal Cord. The vesicular nucleus of the *olive*, which is known as the '*Corpus dentatum*,' and which appears first amongst the network of fibres into which the anterior cornu is resolved, and the outer portion of the anterior column, seems to be intimately connected

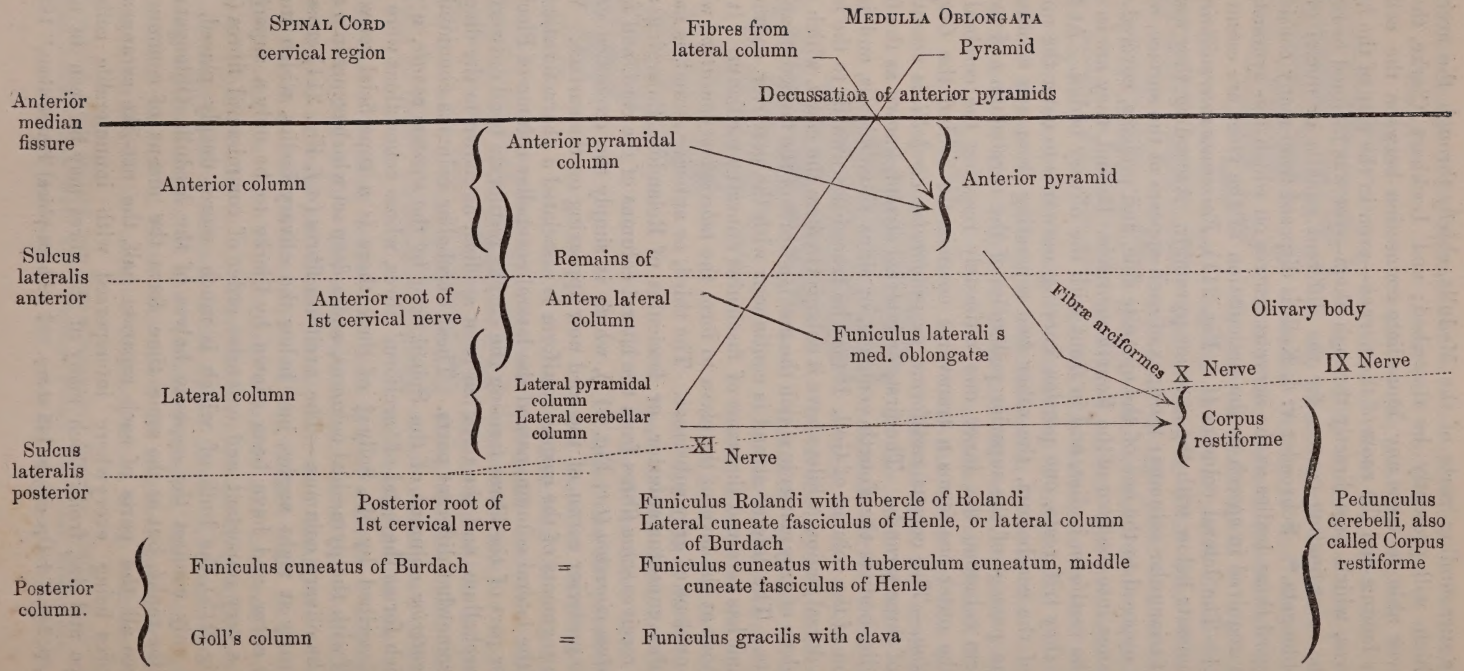
† "Phil. Trans.," 1858, p. 238. See also Meynert, op. cit., p. 528.

with all the surrounding parts of the Medulla, chiefly through the arciform system, which will presently be described; and Lockhart Clarke, though he was never able to trace any immediate connection between the cells of the nuclear laminæ and the roots of the nerves—even in the case of the hypoglossal nerves, which pass directly through them—yet was inclined to regard them as the co-ordinating centres for the different ganglia or nuclei of the Medulla Oblongata.* Schroeder v. d. Kolk is disposed from many considerations to regard these bodies as the nervous centres on which the symmetrical movements required in speech or the articulation of the voice are essentially dependent.†—The lateral columns (*l c*, Fig. 211), *Faisceaux intermédiaires* of Longet, decussate below with the anterior pyramids. Ascending, they assume the form of triangular columns; the apex of each appears at the surface, whilst the base is opposed to the one of the opposite side, and projects, covered with grey substance, into the floor of the Fourth ventricle. Behind, they are in contact with the restiform bodies, and in front with the olivary bodies. At their upper end they trifurcate, one portion curving outwards to enter the middle peduncle of the cerebellum, the other two separating from one another to allow of the passage of the superior peduncles of the cerebellum and part of the restiform columns, the inner one ultimately reaching the cerebral peduncles; the outer one forms a transverse commissure behind the *Corpora Quadrigemina*.—The corpus restiforme, or *pedunculus cerebelli*, is essentially composed of three strands. The first, or internal strand, known as the fasciculus gracilis, bounds the Fourth ventricle, or sinus rhomboidalis, and is the continuation of the column of Goll. It may be traced downwards to the lower part of the dorsal region, whilst above it enlarges to form the *clava*, which contains a nucleus of grey matter in which the median fibres of the fasciculus appear to terminate. The lateral strand is continuous with the posterior column of the cord, and has received the name of fasciculus cuneatus medianus. It also enlarges above at the level of the clava to form the *tuberculum cuneatum*, which contains a nucleus of grey substance. The third, or anterior strand, is named the fasciculus cuneatus anterior, or fasciculus of Rolando. Enlarging as it ascends, it receives some fibres from the lateral columns of the cord, and forms the *tuberculum cinereum* (*t c*, Fig. 211), which is simply the expanded extremity of the posterior cornu of the cord now appearing on the surface. With these three segments of the corpus restiform is associated a characteristic constituent of the lateral column, named the lateral cerebellar column of Flechsig. The greater part of the fibres forming the corpus restiforme bend outwards to enter the cerebellum, and the term has been applied, as shown in the diagram p. 376, to somewhat different parts. These Cerebellar columns communicate with the *anterior* columns of the Spinal Cord by the *stratum zonale*, a portion of which forms the band of 'arciform' fibres, whose connections were first distinctly described by Mr. Solly;‡ of these there is a superficial set which unites itself with the pyramidal columns, and a deep set which comes into relation with the olivary columns.—The arciform fibres (*a f*, Fig. 211) cross the Medulla nearly at right angles, just below the olivary bodies, which indeed they partly cover, and have been shown by Clarke to be only a superficial portion of a very important and extensive order of commissural fibres (well seen in Fig. 215), the bulk of which is much more deeply placed, and which not only connect the opposite halves of the Medulla Oblongata by traversing the raphé, but at the same time form the means of communication between all the parts of each separate half, the net-like arrangement of the fibres being everywhere interspersed with innumerable cells of varied shape and size, from which many of the fibres may be seen to arise.

* Op. cit., p. 245. † Op. cit., p. 148 *et seq.* ‡ "Philosophical Transactions," 1836.



Structural Relations of Spinal Cord to Medulla Oblongata.

The gradual development of the several centres of grey substance in the Medulla Oblongata, and the relations which they bear to the Cerebral nerves, most of which take their origin from this part of the Spinal axis, may be rendered intelligible by a comparison of the following diagrams. The first section here shown (Fig. 213) is made at the level of the lower fibres of origin of the first Spinal nerves. On comparing the shape and position of the grey substance with its appearance, as shown in Fig. 207, it will be observed that the whole of the grey substance is here placed more anteriorly than in that section; that the posterior white columns (*o* and *b*) are of large size, whilst the anterior and antero-lateral columns are comparatively small. In Fig. 214 the grey substance is seen to have relatively increased in size, but to have become somewhat broken up. On each side of the posterior median fissure a remarkable longitudinal column (*b*), containing grey matter in its interior, termed the 'pyramidal column,' is beginning to appear; a second swelling, situated on the Cervix a little more externally to that just mentioned, indicates the commencing appearance of the restiform nucleus of Clarke; still more externally, the Caput Cornu may be seen to be detached and thrown aside from the rest as a distinct mass, which is traversed successively by the vagus and glosso-pharyngeal nerves, and then becomes the principal nucleus of the sensory root of the 5th pair. The decussation of fibres proceeding from the deeper part of the lateral column (between *p* and *a*, Fig. 213) to form the anterior columns is also here well seen, and the central grey substance has re-assumed a triangular form. In the next section (Fig. 215), made about $\frac{1}{4}$ of an inch below the olivary bodies, the grey matter of the posterior pyramids (*b*) on either side of the posterior median fissure is seen to have considerably increased in size; the slight swelling at the base of the Cervix is also now much larger, and has become the grey nucleus of the restiform bodies (*o*), whilst what was the Caput Cornu is pushed still further forwards, and forms a great mass of grey matter at the side of the cord known as the Grey Tubercle of Rolando (*e*, Figs. 216, 217). The commissural direction and arrangement of the fibres of the anterior pyramids are also still apparent. They come principally from the central grey substance, and scarcely at all from the lateral columns. On making a section just below the olivary bodies (Fig. 216), the grey matter is found to occupy almost the whole of the posterior pyramids (*b*), and a large portion of the restiform bodies (*o*), whilst a most delicate and complex system of interlacing fibres surrounds the central canal. The grey tubercle of Rolando having increased in size and reached the surface of the Medulla, appears as a dark streak (*t c*, Fig. 211); the portion of the anterior column which does not decussate has been left white on the right side of this drawing. Two minute

dark spots may be noticed near the bottom of the posterior fissure; these are imbedded in the mass of cells forming the chief ganglionic centres of the spinal accessory nerve, though other and extremely fine rootlets belonging to these nerves may be traced arising from the lateral grey substance and base of the anterior cornu of the spinal cord or tractus intermedio-lateralis, and issuing with the posterior roots of the Spinal nerves as low down as the sixth or seventh cervical vertebra. Fig. 217 is taken from a section made through the lower part of the Olivary body. The posterior pyramids (*b*) still contain much grey matter, and the restiform nucleus and grey tubercle of Rolando are strongly defined. The small central canal has become closely approximated to the bottom of the posterior median fissure, and on either side of it are the ganglionic masses from which the spinal accessory nerve takes its origin, whilst immediately in front of it are two dark spots containing large multipolar cells indicating the ganglia of origin of the hypoglossal nerve, other fibres of which last, like those of the spinal accessory nerve, may be traced downwards, and arise from the upper remains of the anterior cornu, whilst a few of the superior fibres cross the raphé. Anteriorly the windings of the corpus dentatum or olivary nucleus are visible, with a remarkable set of ganglionic cells indicated by G, constituting the vaso-motor centre,* and termed the *antero-lateral* nucleus. These are connected together by a network in the lateral column, and by nerve fibres from the Tubercle of Rolando. The whole central part of the grey substance of the Medulla is shown to be composed of commissural bundles constituting the deep system of arciform fibres described by Lockhart Clarke. The decussation of the anterior pyramids is here much diminished; for the fibres they derive from the lateral columns, which at first were their principal source, have become comparatively few; whilst those that proceed from the posterior columns and central grey substance have been gradually increasing in number, though not in a corresponding proportion. The section shown in Fig. 218 is carried through the Medulla just at the point of the Calamus Scriptorius, and shows that the hypoglossal ganglia have retreated somewhat backward, pushing the mass of ganglionic cells from which the spinal accessory arose, but which now constitute the origin of the *Pneumogastric Nerves* (v), to some extent outwards.† The posterior pyramidal (*b*) and restiform ganglia (*a*) have increased in size, and by their lateral

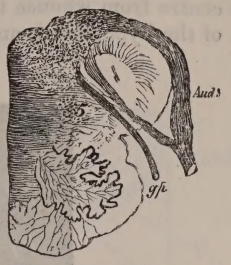
† The vesicular column which gives origin to the fibres of the spinal accessory, becomes the centre for the Vagus about the level of the middle of the olivary bodies. Lockhart Clarke, "Phil. Trans.," 1868 Pt. i. p. 283

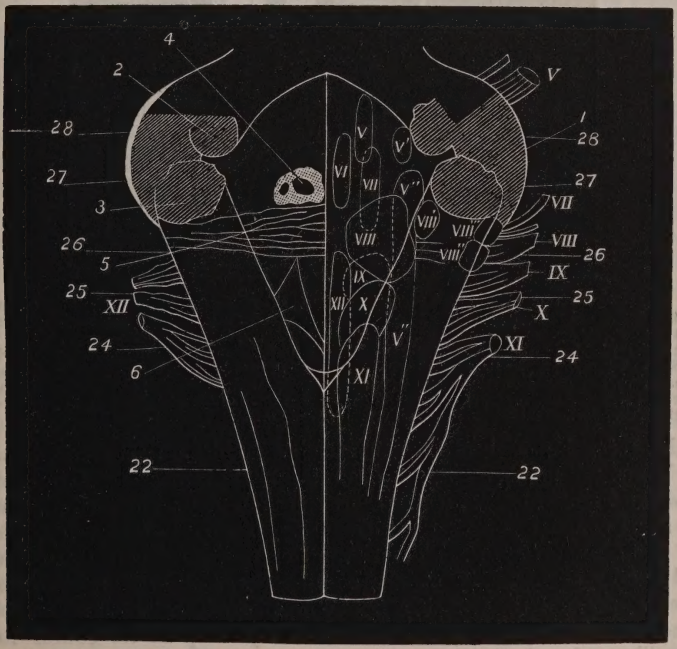
expansion form nearly one continuous mass on each side of the Medulla, which, from the close interlacement of their fibres, presents a spongy appearance, numerous cells being contained in the interstices. The section displayed in Fig. 219 is carried through the upper part of the Medulla Oblongata, and shows the Glosso-Pharyngeal arising at a higher level, but from the same series of ganglionic cells as those from which the Spinal Accessory and Pneumogastric roots have successively arisen, and which are now sunk between two new masses of vesicular substance from which the Auditory nerves take their origin. The Auditory nerve itself is seen to divide into two portions, one curving round the side of the Medulla, and forming the well-known transverse elevation on the floor of the Fourth Ventricle, to terminate in the inner or posterior auditory nucleus and to some extent in the outer nucleus, the other dipping into the substance of the cord in front of the Restiform body to reach the outer nucleus formed by the summit of the posterior pyramid, and apparently by part of the nucleus of the Pneumogastric nerve. The ganglionic cells which give origin to the motor and sensory roots of the 5th nerve are here very apparent. The position of the several nuclei of origin of the different cerebral nerves may be understood from a study of the two accompanying woodcuts.

Fig. 219.



Section through upper part of the Medulla Oblongata.

Fig. 220.



Transparent view of the Medulla from behind. The position of the nerve nuclei is shown on the right hand, and numbered with Roman numerals:—V, Motor nucleus of the Fifth; V′, median, and V″, sensory nucleus of the Fifth; VI, nucleus of the Sixth nerve; VII, facial nucleus; VIII, posterior median nucleus of the auditory nerve; VIII′, anterior median; VIII″, posterior, and VIII‴, anterior lateral auditory nucleus; IX, glosso-pharyngeal nucleus; X, nucleus of vagus; XI, nucleus of Accessorius; XII, nucleus of Hypoglossal; 1, crus cerebelli ad pontem; 2, crus cerebelli ad corpora quadrigemina; 3, crus cerebelli ad medullam; 4, eminentia teres; 5, striæ acusticæ; 6, ala cinerea. The Roman numerals V—XII, indicate the corresponding nerve roots 22—28, section of nerve roots.

The deep origins of the 5th, 6th, and Portio Dura of the 7th, are further shown in the section Fig. 222. The 6th and Portio Dura seem to form almost a loop, and to be continuous with each other through a common ganglionic centre from whence they arise, situated above but in the same line with that of the hypoglossal, and both may be traced to a grey mass in front of the

Fig. 221.

fasciculus teres, but each of these nerves has besides a separate nucleus of its own. When the portio dura of the seventh nerve reaches the fasciculus teres, as shown in Figs. 221, 222, it runs longitudinally down the medulla, and after a very short course again bends transversely *forward* to form a loop along the side of the median furrow. The summit of this curve constitutes the longitudinal bundle of fibres, of which the upper end is seen in sections made just below the fourth ventricle. The loop encloses the nucleus common to it and the sixth, and the lower arm of the loop in its course forwards divides like a brush into separate fibres, which plunge into the motor nucleus of the fifth nerve, and into the superior olivary body, or grey nucleus of the trapezium. As regards the 6th, the lower fibres arise from the ganglion common to it and the portio dura of the 7th, and also from the grey matter of the fasciculus teres, whilst the upper fibres arise from the

upper and inner part of the common ganglion, which may here be regarded as a separate centre or nucleus, as the outer portion, from which the portio dura previously arose, has become much attenuated, and ceases to give origin to the fibres of that nerve. The roots of origin of the 6th pair do not decussate. The close relation which exists between the nuclei of origin of the hypoglossal, glosso-pharyngeal, spinal accessory, vagus, facial, and trigeminal nerves, is of much interest, and serves to explain certain symptoms accompanying various forms of paralysis, in which the muscles concerned in deglutition, vocalization, articulation, and expression are affected. The motor and sensory roots of the 5th are separated from one another at their origin by the Portio Dura. The connection of the motor root with the glosso-pharyngeal nucleus and with the fasciculus teres or nucleus of the 7th, has already been noticed. The Posterior or Sensory root runs down through the front of the grey tubercle or caput cornu posterior, which may be regarded as the continuation of its nucleus, and is in most intimate relation with the fibres of origin of the vagus and glosso-pharyngeal nerves, which pass this portion of the fifth nerve. The origins of the 4th pair of Cerebral nerves have been ascertained to be traceable on either side through the thin lamina constituting the valve of Vieussens, and through the columns forming the lateral boundaries of the Aqueduct of Sylvius, to near the floor of the fourth ventricle;* whilst the third nerve, the apparent origin of which is from the *locus niger* of the Cerebral peduncles, has been followed by Stilling to a grey nucleus underlying the Aqueduct of Sylvius, and has been shown by Clarke to be in close relation with the grey tubercle into which the sensory root of the 5th penetrates, and the nucleus common to the portio dura and abducens nerves. In order to complete the descriptions of the origins of the Cerebral nerves, it is only requisite here to mention that the 2nd pair, or Optic nerves, arise from the posterior part of the Optic thalami and from the Corpora Quadrigemina; whilst the 1st pair, or Olfactory nerves, arise by three roots, the outer one appearing to be connected with the Corpus Striatum of its own side, the inner one with the Lamina Cinerea in front of the Optic commissure, and the middle one springing from a grey nucleus in front of the anterior perforated space.—It will thus be seen that the whole series of the Cephalic nerves, when followed to their origin, arise from grey ganglionic centres situated along the floor of, or just below, the fourth ventricle and the base of the brain. These, there can be little doubt, are more or less intimately connected with one another by longitudinal and transverse commissural fibres, and establish the existence of a Sensory tract, the activity of

FIG. 222.

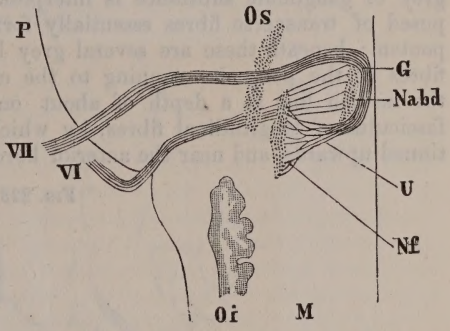

Diagram of the origin of the sixth and Facial Nerves. Transparent lateral view of the Pons. M, medulla oblongata, P, anterior border of the Pons; O i, inferior olivary body; O s, superior olivary body; VII, trunk of the Portio dura raised a little to avoid confusion; G, genu of the intermediate portion; U, deep fibres of origin of the Facial; Nf, Facial nucleus; VI, sixth or abducens nerve; Nabd, nucleus of the abducens. In this view the Facial nucleus is nearest the observer, and the abducens nucleus the most distant, whilst the superior olivary body occupies an intermediate position.

* See Duval, Robin's "Journal de l'Anatomie," 1878, p. 456, who finds that in the cat the root fibres decussate in part.

which is of fundamental importance, as will hereafter be shown, in the origination of ideas and of a certain class of movements which may be termed 'consensual' or 'sensori-motor.'

The Pons Varolii is composed of numerous layers of white matter partly running longitudinally, partly transversely, between which some grey or ganglionic substance is interposed. The superficial layer is composed of transverse fibres essentially forming the processus e cerebello ad pontem; beneath these are several grey laminæ traversed by a deep set of fibres of the pons also running to the crura cerebelli. On each side of the median line at a depth of about one-sixth of an inch is a compact fasciculus of longitudinal fibres, by which the anterior pyramids are continued upwards, and near the anterior border of the pons diverge to enter the

Fig. 223.

cerebral peduncles. Behind these and interlacing with their posterior portion are numerous small masses of grey matter, the *nuclei pontis*. These are succeeded at a greater depth by longitudinal fibres running downwards from the posterior part of the cerebral peduncle. Behind these fibres is the small superior olivary body. The posterior surface of the pons is composed of two pairs of flat longitudinal fasciculi, which are the continuation of the columns of the medulla oblongata. The median pair is the continuation of the fasciculi teretes, which form a projection on the floor of the fourth ventricle and pass upwards to the corpora quadrigemina; the lateral pair (lemniscus) is the continuation of the posterior and lateral columns of the medulla oblongata lying between the olivary body and restiform column.* They ascend on each side to the nates. The transverse fibres of the pons constitute the great commissure of the Cerebellum; and are an extension of the arciform fibres of the medulla oblongata; it will be observed that these fibres not only *surround* the longitudinal bands which

* German, äusseren Halsenstranges.

connect the Cerebral mass with the Spinal Cord, but *pass through* them so as in some degree to isolate the two lateral halves from one another, and to form a complete septum between the anterior and posterior portions of each. These *anterior* and *posterior* tracts of the Crura Cerebri are probably essentially subservient to the *motor* and *sensory* functions. The cells of the grey substance

Bell;—A, A, fibres of the Hemisphere, converging to form the anterior portion of the crus cerebri; B, the same tract, where it passes the crus cerebri; C, the right Pyramidal body, a little above the point of decussation; D, the remaining part of the Pons Varolii, a portion having been dissected off to expose B.—1, olfactory nerve, in outline; 2, union of optic nerves; 3, 3, motor oculi; 4, 4, patheticus; 5, 5, trigeminus; 6, 6, its muscular division; 7, 7, its sensory root; 8, origin of sensory root from the posterior part of the medulla oblongata; 9, abducens oculi; 10, auditory nerve; 11, facial nerve; 12, eighth pair; 13, hypoglossal; 14, spinal nerves; 15, spinal accessory of right side, separated from par vagum and glosso-pharyngeal.

of the pons are generally round, oval, or fusiform, and of about the 1500th of an inch in diameter, and are so connected with nerve fibres in chains or bundles as to form a complete network, the principal chains of which have in general a longitudinal extension, and follow the course of the longitudinal

fasciculi of the anterior pyramids. The general relations of the Sensory tract were represented by Sir Charles Bell in the accompanying diagram (Fig. 223), in which the Medulla is opened on its posterior aspect, the restiform columns separated and turned aside so as to bring into view the posterior pyramids, some of the fibres of which may be traced upwards into the Thalami Optici, whilst they pass through the posterior pyramids into the posterior portion of the *lateral* columns, and also into the *posterior* columns of the Spinal Cord. It will be seen, however, from the foregoing description, that the posterior and lateral columns of the Cord to a great extent terminate in the lower part of the Medulla Oblongata, and that the posterior pyramids and restiform bodies, with their grey nuclei, are essentially new formations, the real function of which is as yet only partially determined. The *Motor* tract (Fig. 224) is brought into view by simply raising the superficial layer of the Pons, and following upwards and downwards the longitudinal fibres which there present themselves. These fibres may be traced upwards into the Corpora Striata, and downwards into the anterior pyramids into the posterior portion of the olivary columns, so that they connect the Corpora Striata with the *anterior*, and with the anterior portion of the *lateral* columns of the Spinal Cord.

446. *Nerves of the Spinal Axis.*—With the Spinal Cord (in its limited sense) there are connected thirty-one pairs of nerves; each of which corresponds to a vertebral segment of the body, and has two sets of roots, an anterior and a posterior, differing in their functional endowments, as already described (§ 418). The anterior roots are usually the smaller; and this is particularly the case with those of the cervical nerves, in which the posterior roots are of remarkable comparative size. In the first Cervical or 'sub-occipital' pair, the anterior roots are sometimes wanting; but there is then a derivation of fibres from the Spinal Accessory, or from the Hypoglossal, or from both. The two roots of the ordinary Spinal nerve unite immediately beyond the ganglion, which is situated on the posterior one; and the trunk thus formed separates immediately into two divisions,—the anterior and the posterior,—each of which contains both afferent and motor fibres. These divisions, of which the anterior is by far the larger, proceed to the anterior and posterior parts of the body respectively; and are chiefly distributed to the skin and the muscles. The anterior branch is that which communicates with the Sympathetic nerve. —In addition to these, however, as we have seen, the cranial prolongation of the Spinal Axis is the centre of all the cephalic nerves, the functions of which, since they are for the most part distinguished by the peculiarity of their endowments, require to be separately noticed.

447. The pair of nerves commonly designated as the *Fifth* of the Cephalic series, or as the *Trigeminus*, is the one which more nearly resembles the ordinary Spinal nerves than does any other of those originating within the cranium. It possesses two distinct sets of roots, of which one is much larger than the other. The anterior *motor* root arises from a nucleus on the floor of the fourth ventricle near the middle line, and this nucleus can be excited by the will through fibres proceeding from the opposite side of the encephalon. The *sensory* fibres arise from a nucleus (see Figs. 220, 221) in the pons; from the posterior cornu of the grey matter of the spinal cord as low down as to the middle of the cervical region; from a nucleus at the side of the aquæductus Sylvii, the fibres of which constitute the trophic root of Meckel; by decussating fibres from the substantia ferruginosa at the upper part of the fourth ventricle; and lastly, some fibres come from the pes of the peduncle of the cerebrum and some from the cerebellum. The fibres of origin of the sensory root communicate with the motor nuclei of every nerve arising from

the medulla oblongata, except the sixth,* which explains many of the reflex phenomena that are presented when the sensory fibres are stimulated. The larger root of the Fifth, like the posterior and larger root of the Spinal nerves, possesses a distinct ganglion, known as the 'Gasserian;' and the fibres of the smaller root, the number of which has been estimated at 9000 to 10,000, do not blend with those of the larger, until the latter have passed through this ganglion. The trunk of the nerve separates into three divisions,—the Ophthalmic, the Superior Maxillary, and the Inferior Maxillary; and it can be easily shown, by careful dissection, that the fibres of the smaller root pass into the last of these divisions alone. When the distribution of this nerve is carefully examined, it is found that the *first* and *second* divisions of it proceed almost entirely to the Skin and Mucous surfaces, only a very small proportion of their fibres being lost in the muscles; whilst of the branches of the *third* division, a large number are distinctly Muscular. Hence analogy, and the facts supplied by anatomical research, would lead to the conclusion that the first two divisions are nerves of sensation only, and that the third division combines sensory and motor endowments. Such an inference is fully borne out by experiment. When the whole trunk is divided within the cranium by the penetration of a sharp instrument (which Magendie, by frequent practice, was able to accomplish), evident signs of acute pain are given. After the incision has been made through the skin, the animal remains quiet until the nerve is touched; but when it is pressed or divided, doleful cries are uttered, which continue for some time, showing the painful effect of stimulating the cut extremity. The common sensibility of all the parts supplied by this nerve is entirely destroyed on the affected side. The jaw does not hang loosely, because it is partly kept up by the muscles of the other side; but it falls in a slight degree; and its movements are seen, when carefully observed, to be somewhat oblique. If the trunk be divided on each side, the whole head is deprived of sensibility; and the animal carries it in a curious vacillating manner, as if it were a foreign body.—If the *Ophthalmic* branch only be divided, all the parts supplied by it are found to have lost their sensibility; but their motions are unimpaired; and all experiments and pathological observations concur in showing it to be essentially a nerve of sensory endowments. A few motor fibres, however, in some animals pass directly to the dilatator pupillæ muscle, and in all secreto-motor fibres are distributed to the the lachrymal gland; by stimulation of these last the secretion of the gland may be excited, whilst after their section a paralytic flow of tears has been observed. When the whole nerve, or its anterior branch, is divided in the rabbit, the pupil is exceedingly contracted, and remains immovable; but in dogs and pigeons it is dilated. The pupil of the other eye is scarcely affected; or, if its dimensions be changed, it soon returns to its natural state. The eyeball, however, speedily becomes inflamed; and the inflammation usually runs on to suppuration and complete disorganization. The commencement of these changes may be commonly noticed within twenty-four hours after the operation; and it is probable they may in part be attributed to the want of the natural secretion, which is necessary to keep the mucous surface of the eye in its healthy condition, and partly to the loss of the sensibility of that surface leading to failure of the protective acts of winking; since, as Snellen† has shown, if the eye be carefully protected from the action of external and injurious agencies, no ill effects are observed. Pathological evidence, however, is not wanting to show that the fifth exerts some influence over the nutritive processes in the parts it supplies, which is probably

* Landois, "Lehrbuch der Physiologie," 1880, p. 667.

† "Ann. d'Oculist.," 1865, t. liii. p. 178.

transmitted through the vaso-motor nerves it contains.* The secretory activity of the lachrymal nerve may be reflectorially excited through the sensory branches of the fifth distributed to the conjunctiva and nose, through the olfactory and optic nerves, and indeed through the sensory branches of the cranial nerves generally.—The *Superior Maxillary* branch, considered in itself, is equally destitute of motor endowments with the ophthalmic; but its connection with other nerves, through the spheno-palatine ganglion, or rather its anastomosing twigs,† introduces vaso-motor fibres into it.—The *Inferior Maxillary* branch is the only one which possesses motor as well as sensory endowments in varying proportions, some being almost exclusively motor, and others as completely of a sensory character. The latter is probably the nature of the Lingual branch, the fibres of which present minute ganglia in the tongue, and there seems good reason to believe, as will hereafter be shown, that this ministers not only to the tactile sensibility of the tongue, but to the sense of Taste. The lingual nerves contain vaso-motor fibres. The muscles put in action by this division are solely those concerned in the masticatory movements.—The *Chorda Tympani*, though essentially destined to excite the sub-maxillary and sub-lingual glands to action, contains motor nerves, distributed to the muscles of the Tongue.‡ The 5th pair is connected, in different parts of its course, with a number of small ganglia belonging to the Sympathetic system. One of the most interesting of these ganglia is the *Ophthalmic* or *Ciliary* (Fig. 225, 29), which is the centre whence the eyeball derives its supply of nerves, sensory, motor, and sympathetic. The ganglion derives its sensory fibres by its 'long root' from the nasal branch of the Ophthalmic division of the 5th pair; its motor fibres, by the 'short root' from the 3rd pair; whilst by another small root it is connected with the cavernous plexus of the Sympathetic system,§ and is thus brought into relation with the Spinal

* See von Gräfe, "Archiv f. Ophthal.," 1854–55, p. 306; Longet, "Physiologie," 1861, vol. ii. p. 486.

† Since the ganglion has been shown by Prévost to be purely sensory. (Brown-Séquard's "Archives de Physiol.," 1868, pp. 7 and 207.)

‡ See Vulpian, "Gazette Hebdomadaire," 1873, No. 3.

§ The functions of this ganglion have been made the subject of particular investigation by Dr. C. Radclyffe Hall ("Edinb. Med. and Surg. Journal," 1846–48), whose most important results are as follows:—

1. The size of the ciliary ganglion is always in direct proportion to the activity of the iris, which in turn always bears a direct relation to the strength and acuteness of vision, and to the nocturnal habits of the animal, and implies a proportionate development of the internal vascular apparatus of the eye.

2. The ganglion is always more intimately connected with the 3rd pair than with any other; the size of the short root being always in direct relation to that of the ganglion, and the ganglion being sometimes a mere swelling on the trunk of the nerve.

3. The fibres derived from the 5th pair do not terminate in the ganglion, but pass onwards through it to the ciliary plexus.

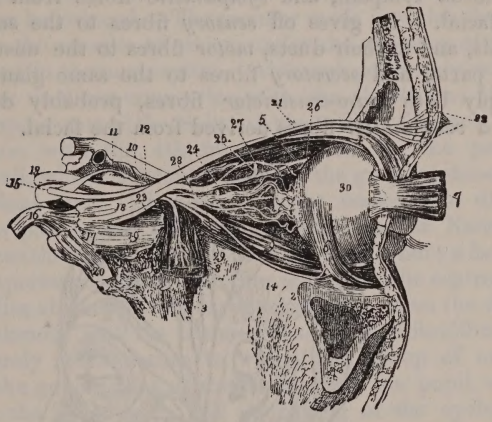
4. In the Rabbit, the iris receives fibres from the 6th pair which do not pass through the ganglion; and it is through this that the contraction of the pupil is produced in that animal by irritation of the 5th pair, which will not produce any effect upon the pupil of the Dog, Cat, or Pigeon, so long as it does not affect the brain to the extent of producing vertigo, nor affect the visual sense in any other way.

5. Irritation of the 5th nerve does not in any animal affect the action of the iris, *after* the division of the cerebral connections of all the other ocular nerves (this is denied by Budge), so that its influence over the movements of the iris must be reflected through the encephalic centres, not through the ophthalmic ganglion.

6. The function of the ganglionic centre itself, as a part of the Sympathetic system, seems to be to bring the 'organic actions' of the eyeball, especially its supply of blood, into harmony with its functional activity; this harmony being produced by the passage of the cerebro-spinal nerves through the ganglion, which excites the synergetic action of its own vesicles and nerve-fibres.—Irritation of the 3rd pair of nerves produces contraction of the pupil; irritation of the cervical portion of the Sympathetic, dilatation. On the other hand, paralysis

axis; for, according to Budge,* these fibres of origin for the Sympathetic nerve arise from two centres: first, from the Spinal Cord between the 6th cervical and the 2nd dorsal vertebra (a part which he terms the Centrum cilio-spinale inferius), the fibres from which pass upward in the great cord of the Sympathetic; and secondly, from another centre situated in the Medulla Oblongata, in immediate proximity to the origin of the Hypoglossal nerve, the fibres from this source passing into the superior cervical ganglion. The *sphenopalatine ganglion*, or ganglion of Meckel, is connected with the 2nd division

FIG. 225.



The *Nerves of the Orbit* seen from the outer side:—1, section of the frontal bone; immediately behind the numeral is the frontal sinus, and, in front, the integument. 2, the superior maxillary bone; the section in front of the numeral exhibits the maxillary sinus. 3, part of the sphenoid bone. 4, the levator palpebræ and superior rectus muscles. 5, the superior oblique muscle. 6, the inferior oblique muscle. 7, the ocular half of the external rectus muscle drawn forwards. 8, the orbital half of the external rectus muscle turned downwards. On this muscle the sixth nerve is seen dividing into branches. 9, the inferior rectus muscle. 10, the optic nerve. 11, the internal carotid artery emerging from the cavernous sinus. 12, the ophthalmic artery. 13, the third nerve. 14, the branch of the third nerve to the inferior oblique muscle. Between this and the sixth nerve 8 is seen the branch which supplies the inferior rectus; its branch to the ophthalmic ganglion is seen proceeding from the upper side of the trunk of the nerve, at the bottom of the orbit. 15, the fourth nerve. 16, the trunk of the fifth nerve. 17, the Gasserian ganglion. 18, the ophthalmic nerve. 19, the superior maxillary nerve. 20, the inferior maxillary nerve. 21, the frontal nerve. 22, its division into branches to supply the integument of the forehead. 23, the lachrymal nerve. 24, the nasal nerve; the small nerve seen in the bifurcation of the nasal and frontal nerve, is one of the branches of the upper division of the third nerve. 25, the nasal nerve passing over the internal rectus muscle to the anterior ethmoidal foramen. 26, the infra-trochlear nerve. 27, a long ciliary branch of the nasal; another long ciliary branch is seen proceeding from the lower aspect of the nerve. 28, the long root of the ophthalmic ganglion, proceeding from the nasal nerve, and receiving the sympathetic root which joins it at an acute angle. 29, the ophthalmic ganglion, giving off from its fore-part the short ciliary nerves. 30, the globe of the eye.

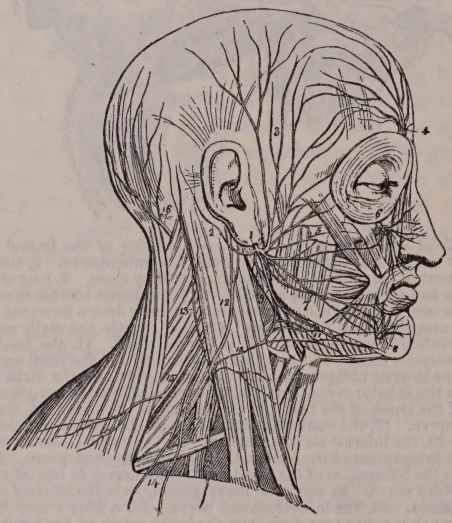
of the 5th as it traverses the sphenopalatine fossa. It receives *sensory* fibres from the superior maxillary division of the 5th, *motor* fibres from the Facial through the nervus petrosus superficialis major, and *sympathetic* fibres from the sympathetic plexus surrounding the carotid artery through the nervus petrosus profundus major. It supplies *motor* branches to the levator palati and azygos uvulæ muscles; *sensory* to the Schneiderian mucous membrane and forepart of the palate, stimulation of which induces sneezing; and probably *vaso-motor* and secretory branches to the same region. The *otic ganglion* is connected with the inner part of the 3rd division of the 5th, just after its exit from the skull. It receives *motor* branches from the inferior maxillary division of the 5th, and from the Facial through the nervus petrosus superficialis minor;

of the 3rd nerve is followed by dilatation; paralysis of the cervical sympathetic (as by section), by contraction of the pupil.

* "Physiologie," 1862, p. 767.

sensory fibres from the auriculo-temporal and from the glosso-pharyngeal nerves through the nervus petrosus superficialis minor; and vaso-motor fibres from the sympathetic plexus surrounding the middle meningeal artery. It supplies *motor* branches to the tensor tympani and tensor palati, and, by its connection with the auriculo-temporal and facial nerves, influences the *secretion* of the Parotid gland. The *submaxillary ganglion* is connected with the lingual nerve after it has been joined by the chorda tympani, and whilst it is lying on the hyoglossus. It receives *sensory* fibres from the lingualis; *motor* from the facial through the chorda tympani; *secretory* through the chorda tympani, and *sympathetic* fibres from the plexus surrounding the facial. It gives off *sensory* fibres to the submaxillary and sublingual glands, and to their ducts, *motor* fibres to the unstriated muscular tissue of these parts, and *secretory* fibres to the same glands; and it also appears to supply both *vaso-constrictor* fibres, probably derived from the sympathetic, and *vaso-dilator* fibres derived from the facial.

FIG. 226.



The distribution of the *Facial Nerve*, and the branches of the Cervical plexus :—1, the facial nerve, escaping from the stylo-mastoid foramen, and crossing the ramus of the lower jaw; the parotid gland has been removed in order to show the nerve more distinctly. 2, the posterior auricular branch; the digastric and stylo-mastoid filaments are seen near the origin of this branch. 3, temporal branches, communicating with (4) the branches of the frontal nerve. 5, facial branches, communicating with (6) the infra-orbital nerve. 7, facial branches, communicating with (8) the mental nerve. 9, cervico-facial branches, communicating with (10) the superficialis colli nerve, and forming a plexus (11) over the submaxillary gland. The distribution of the branches of the facial in a radiating direction over the side of the face, constitutes the pes anserinus. 12, the auricularis magnus nerve, one of the ascending branches of the cervical plexus. 13, the occipitalis minor, ascending along the posterior border of the sterno-mastoid muscle. 14, the superficial and deep descending branches of the cervical plexus. 15, the spinal accessory nerve, giving-off a branch to the external surface of the trapezius muscle. 16, the occipitalis major nerve, the posterior branch of the second cervical nerve.

448. The *Third*, *Fourth*, and *Sixth* pairs, together make up the apparatus of motor nerves, by which the muscles of the Orbit are called into action. The 3rd pair, or *oculo-motorius*, supplies the levator palpebræ, the superior, inferior, and internal recti; the circular fibres of the iris and the ciliary muscle, or Tensor choroideæ. Section or paralysis of the 3rd occasions drooping of the upper eyelid (ptosis); inability to move the eyeball in any direction except

outwards, and downwards and outwards, hence external strabismus; persistent dilatation of the pupil, and, owing to paralysis of the ciliary muscle, loss of accommodation of the eye for near objects. The 4th nerve is confined to the Superior Oblique, and the 6th to the External Rectus. The number of fibres in the 3rd nerve is about 15,000, in the 4th about 1100, in the 6th from 2000 to 2500.* The third and fourth nerves present some traces of sensibility, which in the former nerve is probably derived from the 5th. Chauveau† observes that the deep or intra-cerebral portions of the motor nerves are quite incapable of being excited to action by direct stimulation; though on applying irritation to them at the point where they emerge from the cerebrum, movements can always be induced.—The peculiar mode in which those motor nerves ordinarily excite the muscles to action, under the guidance of the visual sense, will be considered in the next section. Although commonly ranked as cephalic nerves, they have no direct connection with the Cerebrum; their real origin being from the upper part of the Spinal Axis. Thus the roots of the 3rd pair arise in common with the 4th from a nucleus in the pons beneath the Aqueductus Sylvii, which is a continuation of the grey substance of the anterior cornu of the spinal cord. They may also be traced into direct connection with the anterior pair of the Corpora Quadrigemina, or Nates, and with the Lenticular nucleus through the Peduncle of the Cerebrum; a fact of considerable physiological importance, as will hereafter appear. The centre for accommodation of the eye lies above the corpora mammillaria, when the floor of the third ventricle is continuous with the posterior wall of the infundibulum.—The chief actions of a purely *reflex* nature to which this group of nerves ordinarily ministers, are the government of the diameter of the pupil, which is accomplished through the Third pair; and the rolling of the eyeball beneath the upper lid during sleep, as well as in the efforts of sneezing, coughing, &c. But irregular movements of the eyeballs, which must be referred to the same group, are continually seen to accompany various abnormal forms of convulsive action.

449. The Portio Dura of the 7th pair, or Facial Nerve, containing about 4000 to 4500 nerve-fibres, was shown by Bell to be a motor nerve, chiefly distributed to the muscles of the face; it has hence been termed the Nerve of expression. In its passage through the Aqueductus Fallopii, it presents a gangliform enlargement, which is connected by the nervus petrosus superficialis major with the spheno-palatine ganglion of the 5th, and by the nervus petrosus superficialis minor with the otic ganglion.—By these branches the palatine muscles supplied by these ganglia receive their motor power, and some sensory fibres enter the facial, thus accounting for its sensibility when cut at its exit from that canal. It is also connected with the tympanic nerve of Jacobson proceeding from the glosso-pharyngeal, with the auricular of the pneumogastric, and with the upper cervical nerves. The Portio Dura, besides the muscles of the face, supplies the stapedius, the auricular, occipital, stylo-hyoid, and the posterior belly of the digastric muscles. It does *not* supply the muscles of mastication. Its chorda tympani branch joins the lingual of the fifth, and has been shown by Bernard to be the nerve by which the vessels supplying the submaxillary and sublingual glands can be caused to dilate, and both glands excited to active secretion, while other branches minister to taste, and supply the lingualis muscle.—Experimental as well as anatomical researches leave no doubt that the Portio Dura is the *general motor* nerve of the face; ministering to the influence of Volition and of Emotion, and also being the

† "Journal de la Physiologie," tom. v., 1862, p. 272.

channel of the reflex movements concerned in respiration, as of other automatic actions of the muscles.

450. Although the functions of the *Glosso-Pharyngeal* nerve have been heretofore alluded to in part, several questions still remain to be discussed in regard to them. Reasons have been given for the belief that it is chiefly an afferent nerve,—scarcely having any *direct* power of exciting muscular contraction, but conveying impressions to the Medulla Oblongata, which produce *reflex* movements of the motor nerves concerned in deglutition (§ 91).* This view of its function was deduced by Dr. J. Reid from minute anatomical investigation, and from a large number of experiments. Some experimenters assert that they have succeeded in exciting *direct* muscular actions through its trunk; but these actions seem to be limited to the stylo-pharyngei, palato-glossi, and middle constrictor muscles.†—Much controversy has taken place on the question whether this nerve is to be regarded as ministering, partly or exclusively, to the sense of Taste; and many high authorities have ranged themselves on each side. The question involves that of the function of the Lingual branch of the 5th pair; and it is partly to be decided by the anatomical relations of the two nerves. The Glosso-pharyngeal, arising from the nucleus in the floor of the Fourth Ventricle (Figs. 220, 221) near the Olivary body, and just above the vagus nucleus, is principally distributed on the mucous surface of the fauces, and on the posterior third of the dorsum of the tongue; according to Valentin, it sends a branch forwards, on either side, somewhat beneath the lateral margin, which supplies the edges and inferior surface of the tip of the tongue, and inosculates with the Lingual branch of the Fifth. A branch also accompanies the lingual artery, which is perhaps vaso-dilator in function. The experiments of Dr. Alcock, whose conclusions are borne out by Dr. J. Reid, decidedly support the conclusion, that the gustatory sensibility of the anterior part of the tongue is chiefly due to the lingual of the Fifth, being evidently impaired by division of that nerve. On the other hand, it is equally certain that the sense of taste is not destroyed by section of the Lingual nerve on each side; and it seems also well ascertained, that it is impaired by section of the Glosso-pharyngeal nerve.—The pathological evidence bearing upon this point appears somewhat contradictory. Numerous cases have been recorded,‡ in which both common and gustatory sensation were destroyed in the parts of the tongue supplied by the Fifth pair, when that nerve was paralysed; in some of these, the loss of the sense of taste appeared to extend itself to the base of the tongue, but then there was evidence that the Glosso-pharyngeal was involved in the paralysis. On the other hand, cases of paralysis of the 5th pair are related by Mr. Noble and by Vogt,§ in which common sensation was lost, whilst the sense of taste remained in the same parts; and Mr. Noble relates another case,‖ in which there was loss of taste without impairment of common sensation. The cases of Mr. Noble and Vogt would seem to indicate that the Fifth pair does not minister to the sense of Taste; but, as Dr. J. Reid has justly observed, we have no evidence that *all* the filaments of the Fifth pair sent to the tongue were affected; and there is believed to be no case on record in which the whole of the Fifth pair, or of its third branch, was found to be diseased after death, and in which during life the

‖ "Medical Gazette," Nov. 21, 1835.

sense of Taste had been retained in the anterior and middle parts of the tongue. Hence these cases only serve to indicate what is probable on other grounds—viz., that the filaments which convey gustatory impressions are not the same with those that minister to common sensation.—On the whole, then, it seems to be proved by anatomical and experimental evidence, that both the Glosso-pharyngeal and the Fifth pair minister alike to the *tactile* and to the *gustatory* sense; and there is nothing in the pathological facts just noticed, that militates against this conclusion. There seems good reason to believe the Glosso-pharyngeal to be exclusively the nerve through which the impressions made by disagreeable substances taken into the mouth are propagated to the Medulla Oblongata, so as to produce *nausea* and to excite efforts to vomit. The number of fibres in this nerve is about 3500.

451. The *Pneumogastric* nerve takes origin on each side, from a mass of grey matter in the floor of the Fourth ventricle, near the apex of the calamus scriptorius, in common with the Glossopharyngeal above and the Spinal accessory below. (Figs. 220, 221.) It emerges from the medulla oblongata between the olivary and restiform bodies by from 10 to 15 funiculi, which contain about 9000 fibres. Some of these, especially those distributed to the larynx and stomach, are motor, but the larger part of the motor nerves contained in the trunk of the pneumogastric are derived from the Spinal accessory, which gives a very large communicating branch to it shortly after its exit from the skull, and just above the ganglion of the trunk. The nerve presents two ganglia, the ganglion of the root, which is small, and includes only a few of the fibres, and a plexiform enlargement containing some ganglion cells in which the whole of the fibres are implicated. (Fig. 227.) The *ganglion of the root* is connected with the ganglion of the Glosso-pharyngeal, but the function of the connecting twig is unknown. A small meningeal branch joins with the vaso-motor branches from the sympathetic, and supplies the occipital and lateral sinuses. The presence of this nerve perhaps explains

the vomiting that is apt to occur in cases of strong congestion of the head, and in inflammation of the dura mater.* The *auricular* branch is given off from the ganglion of the root, and is connected with the branch from the facial. It is sensory in function, and is distributed to the auditory meatus. The attacks of coughing and of vomiting that have been occasionally reported as a consequence of the presence of foreign bodies in the meatus are attributed to irritation of this nerve. *The ganglion of the trunk* is connected with the spinal accessory, sympathetic and hypoglossal nerves, and with the loop between the first and second cervical nerves. From its upper part it sends motor and sensory branches to the pharyngeal plexus, which supply the three constrictors of the pharynx, and the tensor and levator palati muscles. Strong irritation applied to the plexus may induce reflex vomiting. The functions of the *two laryngeal nerves* have already been sufficiently considered (§ 275), but it may be here repeated that the superior laryngeal nerve, after receiving some branches from the superior cervical ganglion of the sympathetic, supplies vaso-motor branches to the superior thyroid artery; motor branches to the crico-thyroid muscle; sensory branches to the larynx, the excitation of which induces coughing; centripetal fibres, stimulation of which inhibits respiration by closure of the glottis; and lastly, pressor fibres, augmenting blood-pressure by stimulating the vaso-motor centre. The inferior laryngeal nerve supplies motor fibres to the pharynx, œsophagus, and trachea, and to the muscles of the larynx, with the exception of the crico-thyroid. It also contains fibres acting inhibitorily on the respiratory centre. The *depressor* nerve (§ 226), which is given off partly from the superior laryngeal nerve and partly from the trunk of the pneumogastric, contains centripetal fibres, which exert an inhibitory influence on the vaso-motor centres, diminishing the blood pressure in the splanchnic area, and retarding the pulse. The *cardiac branches* of the pneumogastric contain inhibitory, motor, and sensory fibres for the heart. The *pulmonary branches* of the pneumogastric are joined by branches of the sympathetic, after forming an anterior and posterior plexus, some of the branches of which contain ganglion cells, give motor branches to the unstriated muscular tissue of the trachea, bronchi, and bronchia; vaso-motor nerves to the pulmonary vessels, probably chiefly, if not altogether, derived from the first dorsal ganglion of the sympathetic; sensory fibres for the pulmonary mucous membrane throughout; centripetal fibres through which the respiratory centre is excited. The *œsophageal* fibres (forming the plexus gulæ) are both motor and sensory. The *gastric plexus*, formed by the pneumogastric and sympathetic fibres, the left pneumogastric contributing the largest share, is probably essentially motor, but contains some centripetal fibres which excite the salivary secretion. The larger part of the right vagus enters the cœliac plexus, from which fibres accompanying the arteries are distributed to the liver, spleen, pancreas, small intestine, kidneys, and adrenals. Those to the intestine and spleen are motor; those to the other viscera are partly centripetal and partly vaso-motor. Landois gives the following list of centripetal fibres as existing in the Pneumogastric:—Fibres acting on the *vaso-motor centre*, including pressor and depressor fibres; Fibres acting on the *respiratory centre*, including centripetal and inhibitory fibres; Fibres exerting an *inhibitory* action on the *heart*, probably acting in a reflex manner; Fibres acting on the centre for vomiting; Fibres acting inhibitorily on the pancreatic secretion; and, lastly, Fibres exciting reflectorially the formation of sugar in the Liver.

452. In regard to the functions of the *Spinal Accessory* nerve, also, there has been great difference of opinion; the peculiarity of its origin and course

* Landois, "Lehrbuch der Physiologie des Menschen," 1880, p. 684.

having led to the belief, that some very especial purpose is answered by it. It may be said to have three roots of origin (Lockhart Clarke)—one from the anterior grey substance of the Spinal Cord, a second from the nucleus of the Hypoglossal nerve, and a third from the tract of vesicular substance in the Medulla Oblongata, common to it and the Vagus nerve. (Fig. 220, xi.). The trunk contains from 2000 to 2500 tubules. The predominance of motor fibres in its roots, its inosculation with the Pneumogastric, and its probable reception of sensory fibres from the latter, whilst imparting to it motor filaments, have been already referred to. As its trunk passes through the foramen lacerum, it divides into two branches; of which the internal, after giving off some filaments that assist in forming the pharyngeal branch of the Vagus, becomes incorporated with the trunk of that nerve, supplying to it the inhibitory cardiac fibres which run in the Vagus; for if the roots of the spinal accessory be torn out, the inhibitory fibres undergo fatty degeneration, and after the lapse of five or six days stimulation of the Vagus is no longer followed by an inhibitory effect on the movements of the heart, whilst extirpation of the spinal accessory roots is immediately followed by acceleration of the pulse. The external division of the spinal accessory proceeds outwards, and is finally distributed to the sterno-mastoid and trapezius muscles, some of its filaments inosculating with those of the cervical plexus. It receives from the cervical nerves fibres ministering to the special muscular sense of the muscles it supplies. When the external branch is irritated, before it perforates the sterno-mastoid muscle, vigorous convulsive movements of that muscle and of the trapezius are produced; but the animal does not give any signs of pain, unless the nerve be firmly compressed between the forceps, or be included in a tight ligature. Hence it may be inferred that the functions of this nerve are chiefly motor, and that its sensory filaments are few in number. Further, when the nerve has been cut across, or firmly tied, stimulation of the lower end is attended by the same convulsive movements of the muscles: whilst stimulation of the upper end in connection with the spinal cord, after section of the Pneumogastric Nerves, is unattended with any muscular movement. Hence it is clear that the contractions in the sterno-mastoid and trapezius muscles, occasioned by irritating it, are of a direct, not of a reflex character; though the movements which occur in the laryngeal and pharyngeal muscles, on stimulation of the centric extremity, are unquestionably reflex in their nature. The functions of this nerve in regard to Respiration were examined by M. Cl. Bernard;* who has arrived at the conclusion that the Spinal Accessory is essentially a motor nerve, whose action is not exclusively requisite for the *ordinary* movements of respiration, these being provided for by the Pneumogastric and ordinary Spinal nerves; but that its special function is to bring the respiratory movements into accordance with the requirements of Animal life, adapting the actions of the muscles of the larynx and thorax to the production of *voice*, or to general muscular *effort*. The internal branch, which is specially distributed, with the fibres of the Pneumogastric, to the pharynx and larynx, is peculiarly subservient to the former of these purposes; and the external to the latter. This conclusion is sufficiently in accordance with the results obtained by other experimenters, to be received as a probable explanation of the facts which have been observed by them.

* 'Récherches Expérimentales sur les Fonctions du Nerf Spinal,' in "Archives de Médecine," 1844. See also M. Bernard's "Leçons sur la Phys. du Système Nerveux," tom. ii. p. 279 *et seq.*, 1858. M. Vulpian, "Rev. des Cours Scient.," tom. iii. p. 754; and Heidenhain, "Stud. des Physiolog. Inst. zu Breslau," 165, p. 115. Heidenhain, Schiff and Hilton think the Spinal Accessory ministers to both the ordinary respiratory and to the phonetic movements of the larynx.

453. The *Hypoglossal* nerve, or *Motor Linguæ*, the only one that now remains to be considered, contains from 4500 to 5000 nerve-fibres. Its origin is shown in Figs. 220 and 221. That the distribution of this nerve is restricted to the muscles of the tongue, is a point very easily established by anatomical research; and accordingly we find that, long before the time of Sir C. Bell, Willis had spoken of it as the nerve of the motions of articulation, whilst to the Lingual branch of the 5th pair he attributed the power of exercising the sense of taste; and he distinctly stated, that the reason of this organ being supplied with two nerves, is its double function. The inference that it is chiefly, if not entirely a *motor* nerve, which has been founded upon its anatomical distribution is supported also by the nature of its origin, which is usually from a single root, corresponding to the anterior root of the Spinal nerves. Experiment shows that when the trunk of the nerve is stretched, pinched, or galvanized, violent movements of the whole tongue, even to its tip, are occasioned; and also that similar movements take place after division of the nerve, when the cut end most distant from the brain is irritated. When this nerve is divided on one side, the tongue, on the patient being directed to put it out, is projected *towards* the palsied side: this is due to the want of action of the Lingual muscles of that side, which do not aid in pushing-forward the tip; the point is consequently directed only by the muscles of the other side, which will not act in a straight direction, when unantagonized by their fellows; on retraction it is drawn towards the sound side. It is a curious fact, however, that in paralysis from disease the Hypoglossal nerve seems not to be always palsied on the same side with the Facial, but sometimes on the opposite side, an explanation of which may perhaps be found in the disease affecting the decussating fibres described by Duval.* In regard to the degree in which this nerve possesses sensory properties, there is some difference of opinion among physiologists, founded, as it would seem, on a variation in this respect in different animals. Indications of pain are usually given when the trunk is stimulated after its exit from the cranium, and when the tongue is pinched after division of the 5th, but these proceed from its free anastomosis with the loop of the first two cervical nerves, which not improbably impart sensory fibres to it. In some Mammalia, as in the ox, cat and rabbit, the Hypoglossal nerve has been found to possess a small posterior root with a ganglion; in the last named animal, Valentin states that the two trunks pass out from the cranium through separate orifices, and that, after their exit, one may be shown to be sensory, and the other to be motor. Hence, this nerve, which is the lowest of those that originate in the cephalic prolongation of the spinal cord generally known as the Medulla Oblongata, approaches very closely in some of the higher Vertebrata to the regular type of the spinal nerves; and in the frog and some other Amphibia, it is not a cranial nerve at all, but is represented by the first pair of cervical nerves, and though in Man it still manifests an irregularity, in having in general only a single root, yet a double origin has been observed in one instance by Vulpian, whilst the irregularity is often shared by the first cervical nerve, which also has sometimes an anterior root only.†—The Hypoglossal nerve is distributed not merely to the tongue, but to

* It may be questioned, however, whether the Hypoglossal is really paralyzed on the opposite side from the Facial in such cases. An instance has been communicated to the Author by Dr. W. Budd, in which the Hypoglossal nerve was completely divided on one side; and yet the tip of the tongue, when the patient was desired to put it out, was sometimes directed *from* and sometimes *towards* the palsied side; showing that the muscles of either half are sufficient to give any required direction to the whole.

† See Vulpian's 'Essay on the Posterior or Ganglionic root of the Hypoglossal nerve in various animals,' "Journal de la Physiologie," 1862, p. 5.

the muscles of the neck which are concerned in the movements of the larynx;* and the purpose of this distribution is probably to associate them in those actions which are necessary for articulate speech. Though *all* the motions of the tongue are performed through the medium of this nerve, yet it would appear, from pathological phenomena, to have at least two distinct connections with the nervous centres; for in many cases of paralysis, the masticatory movements of the tongue are but little affected, although the power of articulation may be much injured or totally destroyed; and the converse is occasionally noticed. The Hypoglossal nerve, according to Vulpian,† contains vaso-motor fibres, the irritation of which causes the vessels supplying the submaxillary gland to contract. Its section is followed by the dilatation of these vessels.

454. The *general homology* of the Cephalic nerves, considered with reference to the ordinary Spinal, constitutes a study of much interest. It appears, from what has been already stated, that the Pneumogastric, Spinal Accessory, Glosso-pharyngeal, and Hypoglossal nerves, may be considered nearly in the light of ordinary Spinal nerves. They all take their origin exclusively in the Medulla Oblongata; and the want of correspondence in position between their roots and those of the Spinal nerves, is readily accounted for, by the alteration in the direction of the columns of the Spinal cord, which not only decussate laterally, but, as it were, antero-posteriorly (§ 456). The Hypoglossal, as just stated, not unfrequently possesses a sensory in addition to its motor root. The Glosso-pharyngeal, which is principally an afferent nerve, has a small motor root; but most of the motor fibres which answer to it are to be found in the Pneumogastric. That the Pneumogastric and Spinal Accessory together represent a Spinal nerve, may be regarded as probable from what has been already said of their relations.—Leaving these nerves out of the question, therefore, we proceed to the rest. Comparative anatomy, and the study of Embryonic development, alike show that the Spinal Cord and Medulla Oblongata constitute the most essential part of the nervous system in Vertebrata; and that the Cerebral Hemispheres are superadded, as it were, to this. At an early period of development, the Encephalon consists chiefly of four vesicles, which correspond with the ganglionic enlargements of the nervous cord of the Arthropoda, and mark four divisionsof the Cerebro-Spinal axis; and, in accordance with this view, the Osteologist is able to trace, in the bones of the cranium, elements which present an analogy to those that would form four vertebræ, in a much expanded and altered condition. The four pairs of nerves of special sensation,—Auditory, Gustatory, Optic, and Olfactory,—make their way out *through* these four cranial vertebræ respectively. At a later period of development other nerves are interposed *between* these; which, being *intervertebral*, are evidently more analogous to the Spinal nerves, both in situation and function. A separation of the primitive fibres of these takes place, however, during the progress of development, so that their distribution appears irregular. Thus the greater part of the sensory fibres are contained in the large division of the Trigeminus; whilst of the motor fibres, the anterior set chiefly pass forwards as the Oculo-motor and Patheticus; and of the posterior, some form the small division of the Trigeminus, and others unite with the first pair from the Medulla Oblongata to form the Facial. This last fact explains the close union which is found in Fishes and some Amphibia, between that nerve and those proceeding more directly from the Medulla Oblongata. According to Valentin, the Glosso-pharyngeal is the sensory portion of the first pair from the Medulla

* The muscles supplied by the Hypo-glossus are the Lingualis, Stylo-glossus, Hyo-glossus Genio-hyoid, Genio-hyglossus, Thyro-hyoid, Sterno-hyoid, Sterno-thyroid and Omo-hyoid.

† "Gaz. Hebdomadaire," 1873, No. 21.

Oblongata, of which the motor part is chiefly comprehended in the Facial nerve. Although we are accustomed to consider the Fifth pair as *par éminence* the Spinal nerve of the head, the foregoing statements, founded upon the history of development,* show that the nerves of the Orbit really belong to its motor portion; they may consequently be regarded as altogether forming the *first* of the *intervertebral* nerves of the cranium. The Facial and Glosso-pharyngeal appear to constitute the *second;* whilst the Par Vagum and Spinal Accessory, forming the *third* pair, intervene between this and the two Spinal, of which the Hypoglossal may be considered as the first.

455. *Functions of the Spinal Axis.*—In considering the functions of the Spinal Cord, we have to regard it under two aspects;—in the first place, as a *conductor* of nervous force between the Nerve-trunks and the Encephalic centres;—and in the second place, as itself *an independent centre* of nervous power. As a mere conductor of nervous force, its functions are the same as those of a Nerve-trunk:† for if it be divided, all the parts of the body which are solely supplied by nerves arising below the point of section are completely paralyzed, as far as regards sensibility and voluntary movement; no impressions made upon them having the least power to affect the consciousness, and no exertion of the will being able to determine contraction of their muscles. This state of *paraplegia*, which may be experimentally induced in animals, is frequently exhibited in Man as a result of injury or of disease which seriously implicates the Spinal Cord; and as it has been shown that among the lower animals complete reunion of the Cord may take place after complete division, as indicated by the entire restoration of its functional powers and the complete redintegration of its structure,‡ so have we reason to believe that a similar regeneration may take place to a considerable extent in Man, this being marked by the gradual return of sensibility and power of voluntary movement in the lower limbs which had been at first completely paralyzed. This regeneration is of course less likely to occur in cases of disease, when the parts around are in an unhealthy state, than when the paralysis is due to injury, which all the restorative powers of the system are engaged in repairing; but it is to be remembered, that as the injuries which are likely to cause such lesions of the Cord are nearly always attended with severe concussion (it being very rare for the Cord to be accidentally wounded by the penetration of a sharp instrument between the vertebræ, in the mode in which experiments are made upon animals), some of their first effects are attributable to the *shock* which it has sustained; so that the partial recovery which takes place at an early period must not be regarded as the result of regeneration of nervous tissue, which requires a much longer time for its completion. —The conducting power of the entire Spinal Cord being thus established, we have next to inquire whether any difference in endowment can be shown to exist in its several columns.

456. *The Spinal Cord considered as a conductor of sensory impressions and motor impulses.—The posterior columns.*—The posterior columns present two groups of fibres. A median set, known as Goll's column (*c*, Fig. 228), which consists of fibres connecting the posterior roots of the spinal nerves with the grey

* On this point, as well as on the functions of the Cephalic nerves generally, see Prof. Valentin, "De Functionibus Nervorum Cerebralium et Nervi Sympathici," Bernæ, 1839.

† Valentin ("Die Zuckungsgesetze des lebenden Nerven und Muskels," 1863, p. 86) observes that the whole spinal cord behaves like a large nerve on applying electrical stimulation to it, though its irritability is very rapidly exhausted.

‡ See M. Brown-Séquard, in "Gazette Médicale," 1849, No. 45, and 1850, No. 30; also the "Comptes Rendus de la Société de Biologie," 1849, 1850.

nucleus of the funiculus gracilis of the medulla oblongata, whilst the second set, constituting Burdach's cuneate column (*d*), is composed of horizontal fibres of the posterior roots passing to the grey substance, and of longitudinal fibres of the posterior roots and the grey substance ascending to the medulla oblongata. The concurrent testimony of nearly all obervers shows that the posterior columns are highly sensitive, the slightest irritation applied to their surface causing the animal (in the case of the rabbit, dog, and others) to give indications of pain; whilst, after division, stimulation of their cut surfaces not only causes pain, but in many instances induces convulsive movements. The pain is attributable, not to the fibres of the columns themselves, but to the posterior roots of the nerves which traverse them. For, if the Spinal Cord be laid bare, and a few minutes allowed to elapse to permit the immediate effects of the shock and exposure to pass off, the sensibility of the skin of the hind limbs will be found to be everywhere perfect. If a section be now made through the posterior columns (C P, Fig. 229) by passing a tenaculum from side to side and cutting down upon it, and any nerve (N) connected with a part of the cord below the section be stimulated as by pricking, the cries and movements of the animal show clearly that the conduction of painful impressions is not materially interfered with. On the other hand, if after the same preliminary proceedings, the whole of the Spinal Cord be divided transversely (CAL, SG, Fig. 230), with the exception of the posterior columns (CP), it will be found that the sensibility of the posterior limbs is entirely abolished. It is clear, therefore, that the posterior columns are not essentially formed by the continuation of the posterior roots of the spinal nerves. The circumstance that after division of these columns the surface of both the caudal and cephalic segments of the cord is acutely sensitive, is considered by M. Brown-Séquard to be due to the fact that some of the sensory fibres of the posterior roots (Fig. 239) ascend, whilst others descend a little way in these columns before crossing to the opposite side. The view which has been of late gaining ground is that they consist essentially of commissural fibres (as seen in Fig. 231 and at F, Fig. 239), which bring different segments of the cord into connection, and thus effect the co-ordination of complicated reflex movements. On this view, sensory impressions are conducted by the posterior roots to the ganglionic cells in the posterior cornua of the grey substance; from these cells commissural fibres are given off which ascend in the posterior, and perhaps also in the anterior white columns. A communication is thus established with the cells from which the motor fibres are given off that emerge with the anterior roots, and

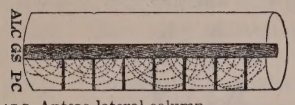
different groups of muscles are in this way brought into combined action. In support of this view is the fact that if the posterior columns are divided at several successive planes, the movements of locomotion become more and more disordered in proportion to the number of the sections (Fig. 231), whilst it is well known that locomotor ataxy, in which affection the power of locomotion and of co-ordinating movements is remarkably impaired, is associated with disease of these columns. In addition it appears that every lesion of them in the lower part of the cord causes a permanent loss of tactile sensibility.*

Fig. 231.



ALC, Antero-lateral column.
GS, Grey substance, and PC, posterior column divided at several points.

Antero-lateral columns.—These columns contain both motor and sensory fibres. They may be subdivided into the pyramid columns (*a* and *g*, Fig. 228), the anterior column proper (*b*), the mixed lateral columns (*e* and *f*), and the cerebellar column (*h*). The pyramid columns connect the grey matter of the Spinal Cord with the ganglion of the pes of the cerebral peduncle, and through this with the convolutions of the cerebrum. The anterior column proper and the mixed lateral columns act as commissures between the reflex centres in the grey matter of the cord and in the medulla oblongata; they contain also the fibres which, ascending in the cord, are the direct continuation of the anterior roots of the spinal nerves. They probably conduct volitional impulses to the groups of motor cells (L, Fig. 239) in the anterior cornua of the grey substance. The cerebellar columns connect the cerebellum with the grey substance of the spinal column, probably with Clarke's columns. Another important set of motor fibres running in the lateral columns is the *vaso-motor* tract, the fibres of which run to the ganglion cells of the grey substance, and then emerge from the cord with the anterior roots, after which they are either directly distributed to the vessels, or join the rami communicantes and enter the sympathetic plexus by which the vessels are surrounded. The fibres subservient to the inhibition of tactile reflex actions descend through the anterior columns of the cord.† The volitional motor fibres, though responding readily to their natural stimulus, answer but slowly to direct irritation. Feeble indications of sensibility can be obtained on irritating them, which has been attributed by Claude Bernard to the presence of recurrent fibres from the posterior roots. Convulsive movements occur in disease (Sclerosis, Charcot) of these columns. If a section of the cord be made dividing

* Schiff, "Centralblatt," 1872, p. 774. See also "Lond. Med. Record," Jan. 15, 1873. Landois, "Lehrbuch der Physiologie," 1880, p. 713. Schiff agrees with Sanders Ezn, who has found that the sensory fibres of the posterior roots in the lumbar region run obliquely upwards for two or three inches before they enter the posterior columns. The posterior colums of the lumbar region in animals (dogs) contain the sensory nerves of the organs of generation, pelvis, anus, and tail. The tactile nerves of the feet lie in other regions of the cord. Hence lesions of the posterior columns in the upper part of the lumbar segment cause anæsthesia in the region of the anus, while the sensation and motion of the posterior extremities remain normal.

† Schiff believes that in lesions of almost any part of the cord a compensatory assumption of the functions of the injured parts by those left intact may take place. The only exception being in the case of the posterior columns. He proposes the term 'Kinesodic' (κίνησις, motion, ὁδός, a path) substance for the tissue by which motor impulses are conveyed along the spinal cord, and he believes the smallest portion is capable of transmitting motor impulses in any direction.

the anterior and lateral columns, all voluntary power on the side of the section is lost. Some diminution, though not entire abolition of voluntary control over the movements of the posterior extremities of the same side is caused by division of the posterior columns and grey substance; the reason for which is clear from an examination of Fig. 233. It is here seen that section of the antero-lateral column (*a b*) divides all the fibres connecting the motor cells in the anterior horns of the grey substance with the brain; whilst section of the grey substance and posterior columns (*c d*) only destroys a certain number of the cells and their communications with the brain, those above and below remaining uninjured, and therefore retaining their activity. Section of one antero-lateral column does not produce quite complete paralysis of the parts on the same side supplied by nerves issuing from the cord behind the section, and it would seem probable that some of the motor fibres run in the anterior parts of the grey substance. In the region situated above the last three cervical vertebræ there is a strand of white substance in the lateral column which serves as the path by which the motor impressions exciting the thoracic movements in respiration are conducted. Lesions of these strands cause absolute and permanent paralysis of the respiratory movements, never compensated by any of the other parts of the cord. Section of the lateral column in the upper cervical region causes, along with a greater or less anæsthesia, complete immobility of the ribs during respiration. *The fibres which transmit motor impulses decussate almost exclusively at the lower part of the Medulla Oblongata.* (See *a r*, Fig. 234.) Hence, if a section of one-half of the Spinal Cord be made (as at 3, Fig. 234), loss of movement on the *same side* occurs, in consequence of the division of the ascending motor fibres (*a r*) from the anterior roots; whilst if the section be made at the level of the decussation of the anterior pyramids (as at 2), paralysis of the muscles of both sides is produced; lastly, if a section be made a little higher (as at 1), paralysis of the muscles of the opposite side results. The presence of various groups of *sensory* fibres in the antero-lateral columns may be regarded as established. Amongst these the most important are those which conduct sensations of *temperature, pressure,* and of *muscular sensibility*,—*i.e.*, the degree of contraction of the muscles. These appear to enter the cord with the posterior roots of the spinal nerves, and to join the ganglion cells in the posterior cornua, from which they pass into the lateral column of their own side, and ascend to the higher centres. *Afferent pressor* fibres also enter the cord with the posterior roots of the spinal nerves, and ascend in the lateral columns. These, after undergoing complete decussation, terminate in the vaso-motor centre, situated in the medulla oblongata. *Depressor* fibres must also be contained in the cord, but the precise position they occupy is unknown. Division of the anterior columns of the cord is followed by a

remarkable tendency to spasmodic contraction in the muscles below the section.

The Grey Substance of the Spinal Cord.—The grey substance of the cord is undoubtedly the channel through which most sensory and painful impressions are conducted to the brain, and in it are contained at different levels those groups of ganglionic cells or nerve centres, which preside over certain special functions. It is remarkable that it does not respond to direct mechanical or electrical stimulation, so that, notwithstanding that it contains so many sensory fibres, it may be pricked, pinched, or electrically irritated, without any indications of pain being given by the animal. This peculiarity, first pointed out by V. Deen, has led Schiff to apply the term *œsthesodic** to it, and he believes that it is capable of conducting in any direction either transverse or longitudinal. It will, however, respond to chemical stimuli, such as the direct application of salt, and the motor centres in it can be excited to action by venous blood, by blood of a higher temperature than 40° and by some poisons.

Fig. 235.

That sensory impressions are chiefly conducted through the grey substance, is shown on the one hand by retaining it intact, whilst all the white columns are divided (Fig. 235), when the sensibility of the hind limbs will be found to be but slightly impaired; and on the other hand by dividing the grey substance alone (Fig. 236), when the sensitiveness of the posterior extremities will be found to be seriously impaired. But it can be further shown by experiment, that some of the sensory fibres of the posterior roots of the spinal nerves do not ascend on their own side, but cross over to the opposite side, either immediately, or after a short ascending or descending course. Thus, if a series of sections be carried from without inwards, the first of which divides the cord as far as to the imaginary line A, Fig. 236, and the succeeding cuts be made progressively deeper and deeper as to B, C, D, and E, it will be found on testing the sensibility of the animal, that the hind limb of the side opposite to that on which the section is made, becomes progressively less and less sensitive. But if the nerve fibres ministering to common sensation on both sides decussate in the spinal cord, it must follow, that on making a longitudinal section from above downwards, along the whole length of the cord, dividing it into two lateral halves, sensibility of both sides of the body should be extinguished, for such a section would obviously divide all the sensory nerves, and, according to M. Brown-Séquard, this is actually the result obtained. Other observers,† however, though admitting there is great diminution of sensibility after a longitudinal division of the cord, maintain that distinct evidence of the conduction of sensory impressions may still be obtained. Perhaps the discrepancies in the results of the operation in the hands of different experimenters are due to different animals having been used; for M. Brown-Séquard has himself observed, that the decussation of the sensory fibres is neither so complete or immediate in Reptiles and Birds as in Mammals, and he has further noticed, that it does not seem to be so perfect in the lumbar as in the dorsal region.‡ He is of opinion that whilst the sensory

‡ Op. cit., p. 37.

fibres of the posterior roots in part run at once to the opposite side of the grey substance, some of them ascend and others descend for a short distance in the grey substance before decussating. Thus, if in one animal the posterior columns be divided above the origin of a particular pair of nerves, and the posterior columns be then dissected back for a short distance (Fig. 237),

Fig. 237.

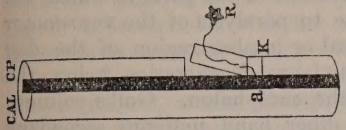

Fig. 238.

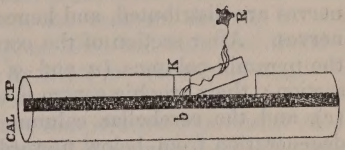

whilst in a second animal a section be made immediately below the origin of the same pair of nerves, and the same dissection be made (Fig. 238), in the former case the flap will only communicate with the grey substance by its lower extremity, and in the latter by its upper extremity. In both instances the animal will continue to give indications when the nerve (R) is pinched, that sensory impressions are still conveyed to the sensorium; thus showing that some of the fibres descend whilst others ascend in the posterior columns, for some distance before entering the grey substance, following in the two cases the course marked in the figures by the lines R, a, R, *b*. By making sections beginning at K, two centimetres from the point to which the posterior column had been reflected, where sensation was found to be still acute, and gradually approximating the attached portion of the posterior column till sensation was found to be abolished, Brown-Séquard ascertained that in the dog the posterior roots after their entry into the posterior columns spread upwards and downwards for a distance of four or five centimetres, or from an inch and a half to one inch and three-quarters before entering the grey substance. Some sensory fibres which enter motor ganglionic cells of the anterior cornua, and are subservient to reflex acts, seem to decussate nearly in the same plane as that at which they enter the cord.* Whilst it would appear that the smallest longitudinal column or transverse layer of the grey substance remaining intact, may serve to a certain limited extent as a means for the conduction of the sensory impressions of either side, it is certain that the central portions of the grey substance are the most effective in the transmission of sensations, much more so at all events than either the anterior or posterior cornua (Brown-Séquard). A very remarkable result of section of one half of the Spinal Cord is that, besides the anæsthesia which is established on the opposite side of the body, there is produced a state of exalted sensibility or *hyperæsthesia* on the same side.† This condition, made apparent by the cries of the animal on the slightest pricking or pinching of the skin, begins to appear a few hours after the operation, rapidly attains its full intensity, and

continues to be well marked for from 17 to 22 days in dogs, and from 12 to 16 days in cats; after which, according to Schiff,* it gradually decreases, until at length the sensibility falls below its normal acuteness. M. Brown-Séquard has, however, observed it to persist in guinea-pigs, though not in a very high degree of intensity, for many months after the operation. The cause of this phenomenon has not been accurately determined. It is certainly accompanied by an increased flow of blood and increased temperature of the parts to which the nerves are distributed, and hence may be due to paralysis of the vaso-motor nerves. After section of the cord in the dorsal or lumbar region of the dog the pyramid-columns (*a* and *g*, Fig. 228) undergo degeneration below the section; their trophic centre is therefore in the encephalon. Goll's column, (*c*), and the cerebellar column (*h*), on the other hand undergo secondary degeneration from below upwards, after section of the cord, and their trophic centre is probably in the ganglia of Clarke's column (x, Fig. 228). Those fibres which do not degenerate after section are probably commissural fibres.

457. *The Cord as an independent centre.*—We have now to consider the Spinal Cord as an independent centre of nervous power, and to inquire whether the movements which are excited through its 'reflex' activity necessarily involve sensation. These movements are most characteristically displayed when the Spinal Cord is cut off from communication with the higher nervous centres; probably rather because the paths pursued by sensory impressions to the higher centres present less resistance, and are, therefore, more readily followed under ordinary circumstances (§ 459), than because (as some suppose) the impulses to reflex movements are ordinarily neutralized and rendered inoperative by an effort of the Will. It is true that those reflex actions of the Spinal Cord, which are necessary to the maintenance of Organic life, and which are equally performed whether the Spinal axis be in communication with the higher Encephalic centres or not, are continually modified or temporarily suspended by the Will; but this is only when we consciously bring the Will to bear upon them; and it is no less certain that we are *not* continually making any such exertions, in order to antagonize movements, which (as we learn from pathological evidence)† would be continually excited but for this neutralizing influence, if such a doctrine were correct.—The readiest demonstration of the independent power of the Spinal Cord is derived from the motions exhibited by the limbs of animals, when irritation is applied to them after section of the Spinal Cord at some point above the entrance of their nerves. Such movements are termed *reflex movements*, and the fact that the sensory impressions after their arrival at the Cord are reflected from it as motor impulses, and that the movements are not the product of direct stimulation applied to the part irritated, is shown by their complete cessation when the nerve trunks are divided, or the substance of the Spinal Cord is broken down. Thus, if a frog be decapitated, its body remains supported on its limbs in the usual position, and will recover this if it be disturbed; irritation of the feet will cause it to leap; and tickling the cloaca with a probe will excite

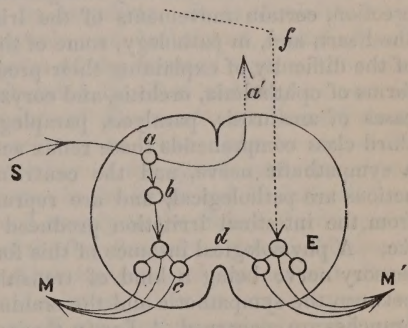
* Op. cit., p. 275.

† See, for example, the case of 'Softening of the Spinal Marrow,' recorded by Dr. Nairne in the "Med.-Chir. Trans.," vol. xxxiv.; in which a portion of the Cord at least an inch long, situated opposite the third and fourth dorsal vertebræ, was "so soft that the slightest pressure of the finger broke it up," being nearly in a fluid state through its whole thickness; yet the patient felt *pain* in his lower limbs, showing that the power of *upward* transmission remained; and although he had lost all voluntary control over the muscles of the lower part of the body, yet they were affected with incessant *choreic* movement (which, according to Dr. Hughlings Jackson, "Edin. Med. Journ.," Oct. 1868, p. 294, originates in embolism of the vessels of the Sensory Ganglia), and these movements were affected in such a marked manner by *emotions*, as plainly to indicate a *downward* transmission of motor power.

efforts to push away the instrument.* So, again, a dog in which the Spinal Cord has been divided in the dorsal region is yet capable of being excited to scratch itself with the posterior limbs, to urinate, and to perform other complex acts. It is to be observed that a slight irritation applied to the peripheral *extremities* of the afferent nerves, is a more powerful excitor of reflex action than a much stronger impression, which occasions acute pain, applied to their *trunks;* thus Mr. Grainger found that he could remove the entire hind leg of a Salamander with the scissors, without the creature moving, or any muscular contraction being produced, if the Spinal Cord had been first divided; yet that by irritation of the foot, especially by heat, in an animal similarly circumstanced, violent convulsive actions were excited in the legs and tail. This fact is important, not only as showing the comparatively powerful effect of impressions upon the cutaneous surface, but also as proving how little relation the amount of reflex action has to the intensity of sensation.

Every reflex act involves the presence of a sensory nerve, a centre composed of ganglionic cells and a motor nerve. An impression made upon the peripheric extremity of the sensory nerve is conducted towards the centre, composed of one or more ganglion cells, where it is converted into an impulse which travels along a motor or secretory nerve, and excites the muscle or gland to which it is distributed to activity. The sensory fibre is hence often called the 'centripetal' or 'afferent' nerve, whilst the other is called 'centrifugal' or 'efferent.' A stronger stimulus must be applied to a sensory nerve to induce a reflex act than is requisite to be applied directly to the motor nerve to cause the same muscle or group of muscles to contract. An example of reflex action is seen in the 'tendon reflex' of the knee, in which, if the legs are crossed and a sharp tap be given to the ligamentum patellæ, the 'quadriceps extensor' muscle instantly contracts; the rapidity and vigour of the contraction enabling important conclusions to be drawn in regard to the functional activity of the Cord. It would seem probable that the sensory or centripetal nervous fibres terminate in the ganglionic cells of the posterior horns of the grey substance of the Cord (Fig. 240). From these, processes are given off, one of which ascends on the opposite side to the sensory ganglia at the base of the Brain, whilst others terminate in cells that are in direct connection with those lying in the anterior

Fig. 240.



s. Sensory root. m. Motor root.

The ordinary course of a sensory impression to the brain is through the ganglion cell, *a*, and fibre, *a'*, which crosses to the opposite half of the cord. In the event of this being divided, the impression is transmitted through an intermediate ganglion cell, *b*, to groups of motor cells in the anterior cornua, *c*, and is thence transmitted through a motor nerve, M, to the muscles of the same side. If the impression be still stronger, the muscles of the opposite side are called into reflex action through the communicating fibre, *d*. The group of motor cells may also be called into action by the voluntary nerve, *f*, which decussates at the lower part of the Medulla Oblongata.

* It has been pointed out by Messrs. Todd and Bowman ("Physiological Anatomy," vol. i. p. 315), that the Spinal Cord of the male frog, at the season of copulation, naturally possesses a state of most extraordinary excitability. The thumb of each anterior extremity at this season becomes considerably enlarged, as is well known to Naturalists. "This enlargement is caused principally by a considerable development of the papillary structure of the skin which covers it; so that large papillæ are formed all over it. A male frog, at this season, has an irresistible propensity to cling to any object, by seizing it between his anterior extremities. It is in this way that he seizes upon, and clings to the female; fixing

horns of the grey substance. Generally speaking, sensory impressions follow the former and simplest path, and any movements that may occur are directed by and subordinate to the will; but if these ascending fibres are divided, then the purely reflex action of the Spinal Cord is exhibited, and the impression is transmitted to one cell or to a group of cells communicating with those in the anterior horn of its own side. If the impression be strong, it is transmitted to the opposite side through the connecting fibres that pass from the cells of one anterior horn, or possibly of one posterior horn, to those of the other. The motor cells of the Cord are brought into communication with the Brain, partly by fibres passing directly to the hemispheres, but chiefly through the intermediation of the cells in the Corpora Striata. The different kinds of reflex action have been well formulated by M. Küss.* They may be classified according to the direction in which both the centripetal and the centrifugal impulse passes. 1. Many of the ordinary reflex actions take place both centripetally and centrifugally through spinal nerves, examples being afforded in deglutition, coughing, sneezing, walking, and the action of the salivary glands, &c., and in pathology by vomiting, tetanus, and epilepsy. 2. A second class almost as numerous includes those reflex actions which take place centripetally through a cranio-spinal nerve, and centrifugally through a motor nerve of the sympathetic system, and most frequently a vaso-motor branch. As examples of this kind of reflex action may be given the excitation of the salivary and gastric glands, blushing or pallor of the skin, erection, certain movements of the iris, certain modifications in the beats of the heart, and, in pathology, some of those phenomena which, in consequence of the difficulty of explaining their production, are called metastatic, as certain forms of ophthalmia, orchitis, and coryza, due to reflex hyperæmia, and certain cases of amaurosis, paralysis, paraplegia, &c., due to reflex anæmia. 3. A third class comprehends those reflex actions in which the centripetal nerve is a sympathetic nerve, and the centrifugal a cranio-spinal. Most of these actions are pathological, and are represented by the convulsions that occur from the intestinal irritation produced by worms, reflex eclampsia, hysteria, &c. A physiological instance of this form occurs in respiration, the vagus or sensory nerve being a kind of transition nerve, bridging over the interval between the sympathetic and the cranio-spinal nerves, so far as its pulmonary branches are concerned. 4. Lastly, there are reflex actions in which both the centripetal and centrifugal conductors are branches of the sympathetic system. Such are the obscure actions that preside over the secretion of the intestinal juices, those which unite the various generative functions, the dilatation of the pupils owing to worms, and many pathological phenomena. From experiments on frogs and other animals, Pflüger has laid down the following "laws" of reflex action:—

his thumbs to each side of her abdomen, and remaining there for weeks, until the ova have been completely expelled. An effort of the Will alone could not keep up the grasp uninterruptedly for so long a time; yet so firm is the hold, that it can with difficulty be relaxed. Whatever is brought in the way of the thumbs, will be caught by the forcible contraction of the anterior limbs; and hence we often find frogs clinging blindly to a piece of wood, or a dead fish, or some other substance which they may chance to meet with. If the finger be placed between the anterior extremities, they will grasp it firmly; nor will they relax their grasp until they are separated by force. If the animal be decapitated whilst the finger is within the grasp of its anterior extremities, they still continue to hold on firmly. The posterior half of the body may be cut away, and yet the anterior extremities will still cling to the finger; but immediately that the segment of the Cord, from which the anterior extremities derive their nerves, has been removed, all their motion ceases. This curious instinct only exists during the period of sexual excitement; for at other periods the excitability of the anterior extremities is considerably less than that of the posterior."

* "Cours de Physiologie," 1873, p. 62.

1. *The law of unilateral reflection.*—In accordance with this law it follows that when, in consequence of irritation of one or more sensory nerves, movement takes place *on one side*, it is always on the *same* side as that to which the irritation was applied.

2. *The law of symmetry.*—It may further be demonstrated that when the impression is sufficiently strong to be irradiated to the muscles of the opposite side, these are always congenerous with those excited to action on the irritated side.

3. *The law of intensity.*—The movements on the irritated side are sometimes equalled in intensity by those of the opposite side, but if they are not equal they are always of superior vigour.

4. *Law of reflex irradiation.*—Lastly, in the *Spinal Cord*, the motor nerve excited is always on the same plane as the sensory nerve that has been irritated, but if the sensory irritation be so powerful as to be propagated beyond this point, it always affects the nerves above and never those below. In the case of the reflex movements due to the Encephalon, however, the irradiation takes place from above downwards towards the Medulla Oblongata, which possesses the power of generalizing all reflex movements; whenever the irradiated excitation in its upward course reaches the Medulla Oblongata, all the nerves arising from the Encephalon are affected.

It is noticeable also that the reflex activity is greatest in young animals. It varies in the different classes of animals, appearing to be most strongly developed in Birds, then in Mammals, and least in Fishes. It is exalted by opium, alcohol, nicotin, and especially by strychnia. It is diminished by acetate of zinc, chloral hydrate, hydrocyanic acid, belladonna, digitalis,* and bromide of potassium.† Like other parts of the nervous system the cells ministering to reflex action can be exhausted by effort and require rest to recover their properties. The experiments of Küssmaul and Tenner‡ show that interruption of the blood supply contrary to what might be expected, has a tendency to exalt the reflex excitability of the spinal cord, though to a much less extent than the nervous centres in the Brain and Medulla Oblongata; complete suppression of the blood supply to the Spinal Cord rapidly causes complete paralysis. In the case of the frog the increased excitability can be demonstrated by removing the cerebral hemispheres of the animal and allowing one of the feet to dip into a weak acid solution; after the lapse of a certain time the leg is withdrawn by a reflex act. If now the lobi optici be moistened with blood, and the experiment be repeated, a longer time is found to elapse before the movement occurs. Reflex acts are greatly enfeebled, or are altogether absent, when the blood is overcharged with oxygen, so that the reflex contractions consequent on the administration of strychnia, brucia, thebaia, and caffein are suppressed, in animals to which they have been given, by vigorous artificial respiration.§ Reflex acts are performed more rapidly than voluntary acts; more quickly by the corpora quadrigemina than by the medulla oblongata, and more quickly by the medulla oblongata than by the spinal cord. Reflex actions can also be inhibited by powerful stimulation of a sensory nerve, and also by certain poisons, as curare, digitalis, and chloroform. The time occupied in the performance of a reflex act is independent of the strength of the stimulus. The time occupied in the performance of a reflex act on the same side of the body as that on which the irritation is applied is

* Weil, "Centralblatt," 1871, p. 839. † Meihuisen, "Centralblatt," 1873, p. 88.

‡ "On the Nature and Origin of Epileptiform Convulsions," New Syd. Soc. Translation, 1859, p. 54.

§ See Leube and Uspensky, "Centralblatt," 1868, pp. 41 and 677; Uspensky, Reichert, and Du Bois-Reymond's "Archiv," 1868, p. 401.

shorter than on the opposite side, and the longer period required in the latter instance is termed the 'period of reflex conduction.' In the frog the time occupied in the performance of a reflex act on the *same* side varies from 0·008 to 0·005 sec. But to perform a reflex act on the opposite side requires a space of time longer by one-third. This difference, however, becomes very short, or almost imperceptible, when the irritation applied is very strong. Exhaustion of the spinal cord prolongs the duration of the 'reflex time.' The rapidity of conduction is not augmented by strychnia.* Cold retards it. Reflex actions may be inhibited by the will. Thus, whilst a sudden and loud sound occurring unexpectedly causes a start or contraction of the muscles generally, the body can be kept motionless by an effort of the will, if we are prepared for its occurrence. In like manner the contraction of the orbicularis palpebrarum when the conjunctiva is touched can be controlled or prevented by a determination to keep the eyes open, and the strong disposition to smile when the nose is lightly tickled can be overridden by the will. Some reflex acts, and especially those which are not performed under the influence of the will, such as the movements of the Iris and the act of delivery, cannot be suppressed by the will. The inhibition of reflex acts may also be effected by the powerful stimulation of any sensory nerve; thus the movements consequent on tickling may be prevented by biting the tongue, and this is observed even if the nerve be the one which itself excites the reflex action as in the case of rubbing the nose to prevent sneezing. Violent pain inhibits speech and locomotion as is seen in *tic*. An inhibitory centre, known as Setschenow's centre, is situated in the Frog in the lobus opticus of each side, the removal of which is followed by increased reflex excitability of all the parts below the section, and a similar centre is believed to exist in all Vertebrata.

458. That the movements executed by the limbs of the lower animals, when these are no longer connected by the Spinal Cord with the Encephalon, but remain in nervous connection with the Cord itself, do not take place through the intermediation of sensation, might be supposed to be sufficiently proved by the simple fact, that division of the Cord in Man, and hence by inference in the lower animals, reduces the parts below to a state of complete insensibility. But, on the other hand, the very performance, by decapitated animals of inferior tribes, of actions which had not been witnessed in Man under similar circumstances, has been held to indicate that the Spinal Cord in them has an endowment which *his* does not possess. The possibility of such an explanation, however unconformable to that analogy throughout organized nature, which, the more it is studied, the more invariably is found to guide to truth, could not be disproved. Whatever experiments on decapitated animals were appealed to, in support of the doctrine that the Encephalon contains the only seat of sensibility, could be met by a simple denial that the Spinal Cord is everywhere as destitute of that endowment as it appears to be in Man. The cases of profound Sleep and Apoplexy might be cited as examples of reflex action without consciousness; but these have been met by the assertion, that in such conditions, sensations are *felt*, though they are not *remembered*. It is difficult, however, to apply such an explanation to the case of anencephalous human infants (in which all the ordinary reflex actions have been exhibited, with an entire absence of brain), without supposing that the Medulla Oblongata is the seat of a sensibility which we know that the lower part of the Spinal Cord does not possess; and of this there is no evidence whatever. —Experiments on the lower animals, then, and observation of the phenomena

* See Rosenthal, Ueber Reflexe,' "Centralblatt f. d. Med. Wiss," 1877, p. 8.

manifested by apoplectic patients and anencephalous infants, *might* lead to the conclusion that the Spinal Cord does not itself possess sensibility, and that its reflex actions are independent of sensation. At this conclusion, Unzer, Prochaska, Sir G. Blane, Flourens, and other physiologists had arrived; but it was not until special attention was directed to the subject by Dr. M. Hall, that facts were obtained by which a positive statement of it could be supported. For the question might have been continually asked,—If the Spinal Cord in Man be precisely analogous in function to that of the lower Vertebrata, why are not *its* reflex phenomena manifested, when a portion of it is severed from the rest by disease or injury? The answer to this question is twofold. In the first place, simple division of the cord with a sharp instrument leaves the separated portion in a state of much more complete integrity, and therefore in a state much more fit for the performance of its peculiar functions, than it ordinarily is after disease or violent injury; and as the former method of division is one with which the Physiologist is not likely to meet in Man as a result of accident, and which he cannot experimentally put in practice, the cases in which reflex actions would be manifested are likely to be comparatively few. But secondly, a sufficient number of such instances *have* now been accumulated to prove that the occurrence is by no means so rare as might have been supposed; and that nothing is required but patient observation to throw a great light on this interesting question from the phenomena of disease. A most valuable collection of such cases, occurring within his own experience, has been published by Dr. W. Budd.*

459. So many cases of this kind have now occurred, that it may be considered as a demonstrated fact, that the Spinal Cord, or insulated portions of it, may serve in Man, no less than in the lower animals, as the centre of very energetic reflex actions, when the Encephalic power which ordinarily operates through it is suspended or destroyed, or when it is prevented from influencing the Spinal nerves by such an injury to the Cord above their points of connection with it, as prevents the transmission of nervous polarity: and it is further evident that these movements are not more dependent upon Sensation than they are upon the Will, since they may be excited without the consciousness of the individual, even when this is fully directed to the part.† And we thus have adequate ground for the assertion, that the movements which may be called forth by stimulation in the states of profound Sleep or Coma, are not to be held to indicate that conscious sensation is even momentarily excited; since we know that the reflex power of the Spinal Cord may be called into action by impressions which do not travel onwards to the sensorium, or which are powerless to affect the consciousness even when they arrive there. These abnormal reflex actions of the Spinal Cord of Man, though often powerful, have much less regularity and apparent *purposiveness*, than have the movements executed by the lower Vertebrata (as the Frog, § 457) after decapitation or section of the cord; the latter approaching, in respect to these qualities, to the reflex movements of Arthropoda—as is well seen in the following experiment, which is much relied on by those who hold that the Spinal Cord is the

* "Medico-Chirurgical Transactions," vol. xxii.

† The Author was informed by his friend Sir James Paget, that among the notes left by John Hunter (which furnished some of the materials for the admirable Catalogue of the Pathological portion of the Hunterian Museum drawn up by Sir James Paget), there was the record of a case of paraplegia, in which it appeared that Hunter had witnessed reflex movements of the legs in which sensation did not participate. When the patient was asked whether he felt the irritation by which the motions were excited, he significantly replied—glancing at his limbs,—"No, Sir; but you see *my legs* do."

seat of sensorial functions.* If a frog be decapitated and acetic acid be applied over the internal condyle of the femur, the animal will wipe away the acid with the foot of the same side; but if this be cut off, after some ineffectual efforts, and a short period of hesitation, it will perform the same action with the foot of the opposite side. The explanation seems to be that (in accordance with the laws laid down by Pflüger) when the skin of one side of the body is irritated, the motor nerves of that side respond to the impression, but this being prevented and the sensory impression continuing, the impression is radiated to the motor ganglia of the opposite side, the muscles supplied by which are accordingly brought into play. We have here exhibited the results of a mechanical disposition of parts, and not the operation of a conscious intelligence. It must not hence be inferred, however, that there is any essential difference in the endowments of the Spinal Cord, between Man and the lower animals; or that any *psychical* agency exists in the latter case which is wanting in the former. We have already seen that the existence of even the most perfectly adapted combination of different muscular actions, all obviously bearing upon a definite object, cannot in itself justify our attributing this combination to design or voluntary choice on the part of the organism that executes it (§ 404); whilst, on the other hand, to remove these movements in any case from the category of *automatic* actions, would be to assign to the Spinal Cord a power of consciously selecting and directing them, such as we have every reason for believing to be limited to the higher parts of the Cerebro-Spinal centres. Now the very *uniformity* of the movements in question, or the slight variation in effect which has been observed to follow the application of different stimuli, is itself an indication that they do *not* proceed from any purposive choice, but depend upon the special endowments of those centres of reflex action, whence the impulses that call them forth immediately issue to the nerves: and hence the more marked adaptiveness of the reflex actions performed by many of the lower tribes of animals, can only be held to indicate that a larger share of such adaptation is effected in them by what may be termed the *mechanism* of their nervous centres, and that less is left to voluntary choice and direction, which can only be safely trusted where a considerable amount of intelligence exists to guide it;—a conclusion which accords well with what has been already stated, respecting the structural differences that seem to exist between the Spinal Cord of Man, and that of the inferior Vertebrata. A peculiar condition described by Schiff† as Analgesia may here be alluded to. It consists in the retention of the capability of perceiving sensations of *touch*, though the most severe injuries to nerves produce no sensations of pain. This condition may be induced, according to Schiff, by division of the whole Spinal Cord with the exception of the posterior columns, also by rapid abstraction of blood; and it may be observed in the early stages of the administration of ether or chloroform. It seems to be questionable, however, whether this is not rather to be considered as a state of blunted common sensibility. As a sequel to the preceding consideration of the Spinal Cord as a conductor of motor and sensory impressions, and as an independent centre, the following

* See Pflüger, "Die sensorischen Functionen des Rückenmarks," Berlin, 1853; see also an able review in the "Med.-Chir. Review" for Jan. 1864, in which the above experiment is quoted. The doctrine of the independent volitional as well as sensorial power of the Spinal Cord is ingeniously sustained in Mr. G. H. Lewes's "Physiology of Common Life," vol. ii.; whilst the opposite side is taken in a review upon that work contained in the "Med.-Chir. Review," vol. xxvi. 1860, p. 423.

† "Physiologie," 1859, p. 252.

summary by M. Brown-Séquard* of the results in Man of any injury damaging the whole transverse thickness of a small portion of one lateral half of the cord is instructive. There may be observed under these circumstances:—A. On the same side—1. Paralysis of voluntary motion; 2. Hyperæsthesia for sense of contact, for tickling, for pain, and for temperature in the paralyzed parts; 3. An anæsthetic zone of small extent, corresponding to the parts supplied by nerves which take their origin from that part of the Spinal Cord situated immediately below the lesion; 4. Hyperæsthesia in a greater or less extent of surface above the zone of diminished sensibility; 5. Absolute or relative elevation of temperature in the paralyzed parts, and often also in those parts of which the sensibility is exalted, but not in the parts which are not paralyzed; 6. Phenomena indicating paralysis of the origins of the great sympathetic nerve in the neck, when the lesion has occurred in the cervico-brachial enlargement. B. On the opposite side—1. Complete anæsthesia as regards contact, tickling, pain, and temperature in the parts which correspond to those that are paralyzed on the opposite side; 2. Perfect preservation of the voluntary movements and of the muscular sense; 3. A zone of exalted sensibility of small extent and feeble in degree, situated in the parts above those the sensibility of which is diminished. From his numerous observations, he believes he is justified in drawing the conclusion already stated (§§ 456, 457), that complete decussation of the conductors of the various kinds of sensibility occurs in the cord, with the exception of those which convey the muscular sense.

460. Experiment has shown that although the grey matter of the spinal cord forms a continuous column throughout its whole length, a certain localization of function exists in it by means of which different segments are devoted to the performance of definite functions, and these may be regarded as separate centres. About eight of these centres have been distinguished—namely, 1. The centre for effecting dilatation of the pupil which is situated in the lower part of the cervical and in the upper part of the dorsal region of the spinal cord, extending as low as to the third dorsal vertebra. It is excited by the absence of light, both pupils dilating simultaneously when one eye is covered. Unilateral extirpation of this region of the cord causes the iris of the same side to contract. The motor fibres emerge in the anterior roots of the two lower cervical and two upper dorsal nerves, and enter the cervical sympathetic nerve. 2. The sweat centre (§ 377). 3. The ano-spinal centre which governs the act of defæcation and is situated in the dog at the level of the 5th lumbar vertebra. The afferent fibres of this centre are the hæmorrhoidal and the inferior mesenteric nerves; the efferent are contained in the pudendal plexus, and are distributed to the sphincter ani muscle. 4. The vesico-spinal centre. The centre for the sphincter vesicæ lies in the spinal cord of the dog at about the level of the 5th lumbar vertebra, and in the rabbit at the level of the 7th. The centre for the detrusor urinæ is, in rabbits, opposite the fourth lumbar vertebra.† 5. The centre for erection of the penis. This lies in the lumbar region of the cord. The afferent fibres are the sensory nerves of the penis; the efferent are the remarkable nervi erigentes, stimulation of which effects dilatation of the vessels of the penis, and which issue in company with the first, second, and third sacral nerves; and the branches distributed to the erector penis and transversus perinei muscles. 6. The centre for emission of semen. This, which is named Budge's "centrum genito-spinale" is also situated in rabbits

* "Journal de la Physiologie," vol. vi., Oct. 1863, published in December, 1865, pp. 124, 232, and 581; and "Archives de Physiologie," 1868, p. 610.

† Budge, "Physiologie," 1862, p. 510.

opposite the fourth lumbar vertebra. The afferent fibres are the sensory dorsal nerves of the penis. The efferent fibres emerge with the fourth and fifth lumbar nerves, and passing into the great sympathetic are distributed to the vasa deferentia and vesiculæ seminales, whilst others issue with the third and fourth sacral nerves and entering the perineal nerves, are distributed to the accelerator urinæ muscle, by which the semen is propelled from the urethra with considerable force. 7. The centre for parturition. This like the two former lies in the lumbar region, and both the afferent and efferent fibres run in the uterine plexus. 8. The vaso-motor centre. This which might more correctly be described as a series of centres governing the contraction as well as the dilatation of the vessels of certain regions or districts extends through the whole length of the spinal axis. All of these centres, in addition to the afferent fibres by which their reflex activity is ordinarily called into play, are connected with other centres in the Medulla oblongata and Brain, which are capable of exerting a powerful influence either in still further stimulating them or in arresting or inhibiting their action. When, however, the specific energy of the reflex centre is fully exerted, the superior centres cease to act upon them, and the automatic and co-ordinated character of the acts performed in subordination to them becomes manifest. This is strikingly shown in the phenomena of parturition. In this act the movements seem to be to a certain extent only dependent upon the Spinal cord; for, as will be shown hereafter (CHAP XVIII., Sect. 3), the contractions of the Uterus, which are alone sufficient to expel the fœtus when there is no considerable resistance, are not to be regarded as altogether 'reflex;' and it is only in the co-operation of those associated muscles which come into play in the second stage of labour, when the head is passing through the os uteri and is engaged in the pelvic cavity, that the assistance of the Spinal cord and its nerves is called in. These movements, like those of Defecation, may be to a certain extent promoted or restrained by voluntary effort; but when the exciting influence (the pressure of the head against the parietes of the vaginal canal) has once been fully brought into operation by the uterine contractions, the Will has little power over them, either in one way or the other. The antagonizing influence of the sphincter vaginæ seems, like that of the sphincter ani, to be dependent upon the Spinal cord; and thus it happens that when its tension and that of other muscular parts has been destroyed by death, whilst the uterus still retains its contractility, the power of the latter has sufficed for the completion of the parturient process, the child being expelled after the respiratory movements have ceased.

461. The endowments of the *Medulla Oblongata* do not seem to differ from those of the Spinal cord in any other respect than in the special nature of the reflex movements to which it ministers. This part of the Cranio-spinal axis has been regarded by some Physiologists, indeed, as the peculiar seat of vitality; since, although the other encephalic masses may be withdrawn from above, and nearly the whole of the Spinal cord may be removed from below, without the destruction of life, yet a complete stop is put to the current of vital action when the Medulla oblongata is destroyed. But the dependence of the vital activity of the body generally upon the functional integrity of this part of the nervous system, is simply consequent upon the fact that the Medulla oblongata contains the chief ganglionic centre of the Respiratory movements;* upon the integrity of which, as already shown (CHAP. IX. Sect. 3), the continuance of the Circulation is dependent, and with this, the maintenance of

* Brown-Séquard considers that the whole base of the Encephalon in Man is implicated in Respiration ("Central Nervous System," p. 191).

the organic functions generally. Where, however, as in the Frog, the respiratory activity of the skin is equal to or greater than that of the lungs, the removal of the Medulla oblongata is not attended by fatal results, and M. Brown-Séquard* has kept frogs thus mutilated, alive for eight months. Besides the respiratory, the following Ganglionic centres are situated within the Medulla oblongata:—1. The centre for effecting closure of the lids by reflex action, the afferent fibres being contained in the optic nerves and in those branches of the Fifth which are distributed to the conjunctiva and to the skin of the lids. The efferent fibres are contained in the Facial nerves, and are distributed to the orbicularis palpebrarum, corrugator supercilii, and other muscles of the face, which can exert a protective influence over the eye. This centre can be excited by an effort of the will. 2. The centre for sneezing, the afferent nerves for which are contained in the olfactory and in the Fifth pairs of nerves; whilst the efferent are contained in the spinal nerves distributed to the muscles of expiration. This centre cannot be called into action by the will. 3. The centre for coughing, the sensory fibres of which run in the vagus, whilst the motor are distributed to the expiratory muscles. 4. The centre for sucking, the afferent fibres of which run in the Fifth, and perhaps in the Glosso-pharyngeal nerves, and the motor or efferent in the branches of the Seventh pair supplying the lips. Those of the Hypoglossal to the tongue and those of the third division of the Fifth to the elevators and depressors of the lower jaw. 5. The centre for the movements of Mastication. The afferent and efferent nerves being the same as the preceding, with the addition of motor fibres from the Facial, supplying the buccinator muscle. 6. The centre for the salivary secretion, as is shown by stimulating the floor of the fourth ventricle, which causes a flow of saliva. This diminishes if the chorda tympani be divided, and ceases when the cervical sympathetic is also cut. 7. The centre for the movements of deglutition. The afferent fibres here are branches of the Fifth, Glosso-pharyngeal and Vagus nerves distributed to the mouth, gums, and pharynx, and the motor nerves are branches of the motor nerves entering into the formation of the pharyngeal plexus. 8. The centre governing the act of vomiting. 9. The centre controlling the dilatator pupillæ muscle and the smooth muscles of the orbit and lids. The fibres run partly through the Fifth and partly through the spinal cord to the cilio-spinal region, from whence they pass into the cervical sympathetic. 10. The centre of mimetic expression. 11. The centre of speech—so far as this is connected with the movements of the lips, tongue, and larynx. 12. The centres governing the movements of the heart (accelerating and inhibitory ganglia). 13. The dominant or chief part of the vaso-motor centre. 14. A centre exerting a co-ordinating influence upon the reflex centres of the spinal cord. 15. A convulsive centre, which, on being excited by the circulation through it of venous blood, or by sudden withdrawal of blood, or by mechanical lesion, liberates impulses which induce violent general convulsions. 16. The centre controlling the secretion of sweat, according to Salkowsky.

Olivary Bodies.—It is remarked by Lockhart Clarke† that it is probable the Olivary bodies are not only the centres through which different movements are co-ordinated for expressing the passions and emotions, but that they are the motor centres through which different movements are effected by sudden, violent, or peculiar impressions on the special senses; for they are intimately connected with all the sensory ganglia of the Medulla,—with the grey tubercle (trigeminus), the vagal nucleus, the post-pyramidal and restiform nuclei (auditory ganglia),

* "Central Nervous System," 1860, p. 191.

† "Philosophical Transactions," 1863, p. 319.

and the corpora quadrigemina (optic ganglia) through the fillet, and not improbably with the parts about the root of the olfactory bulb, since he has been able to trace the olivary columns nearly to the anterior perforated space. As regards the functions of the several strands composing the Medulla oblongata, little is known, excepting that the anterior pyramids are the conductors for voluntary motor impulses. The Corpora restiformia, which constitute the inferior penduncles of the Cerebellum, do not appear, according to M. Brown-Séquard,* to give passage to any of the conductors of *sensory* impressions proceeding from the trunk, limbs, or head. It is remarkable, however, that after they have been transversely divided, hyperæsthesia is produced in every part of the trunk and limbs. On the whole the Spinal cord, with its encephalic prolongation, may be said to supply by its 'reflex power' *the conditions requisite for the maintenance of the various muscular movements which are essential to the continuance of the organic processes;* and, as Dr. Hall has pointed out, it especially governs the various orifices of ingress and egress.

462. The Spinal Axis is not merely the instrument whereby the movements essential to the maintenance of the organic functions are sustained; it is also subservient to other muscular actions, whose character is essentially *protective.* Thus it was ascertained by Dr. M. Hall† that, if the functions of the Brain be suspended or destroyed without injury to the Spinal cord and its nerves, the Orbicularis muscle will contract, so as to occasion the closure of the eyelids, upon their tarsal margin being touched with a feather. This fact is interesting in several points of view. In the first place, it is a characteristic example of an adaptive action, occurring under circumstances in which volition cannot be imagined to guide it, and in which there is no valid reason to believe that sensation directs it. Further, it explains the almost irresistible nature of the tendency to winking, which is performed at short intervals by the contraction of the Orbicularis muscle; this is evidently a reflex action, capable of being in some degree restrained (like that of respiration) by the will, but only until such time as the stimulus (resulting perhaps from the collection of minute particles of dust upon the eyes, or from the dryness of their surface in consequence of evaporation), becomes too strong to be any longer resisted. The nervous channel through which this action is performed, is completed by the first branch of the Fifth and the Portio Dura of the Seventh. Again, we have in sleep or in apoplexy an example of this purely-spinal action, unbalanced by the influence of the will, which, in the waking state, antagonizes it by calling the levator palpebræ into action. As soon as the will ceases to act, the lids droop, and close over the eye so as to protect it; and if those of a sleeping person be separated by the hand, they will be found presently to return. Hence, as in studying the respiratory and other movements, we are led to perceive that it is the Brain alone which is torpid during sleep, and whose functions are affected by this torpidity. As Dr. M. Hall very justly remarks, "the Spinal system never sleeps;" it is constantly in activity; and it is thus that, in all periods and phases of Life, the movements which are essential to its continued maintenance are kept up without sensible effort.—The closure of the pupil against a strong light, is another movement of the same protective tendency. The contraction of the pupil is immediately caused by the Third pair, or Motor oculi, as is easily shown by irritating the trunk of that nerve and observing the result; but the stimulus which excites it is conveyed through the Optic nerve. Yet although the contraction of the pupil is usually in close accordance with the *sensation* occasioned by the impression of light upon

* "Philosophical Transactions," 1868, p. 27.

† "Memoirs on the Nervous System," 1837, p. 61.

the retina, yet there is evidence to prove that the sensation of light is not always necessary: for even when the sight of both eyes has been entirely destroyed by amaurosis, the normal actions have been witnessed in the pupil, in accordance with the varying degrees of light impinging on the retina. Such cases seem to indicate that the motion results from an *impression* upon the retina, which impression being conducted to the Sensorium ordinarily produces a sensation; but that even where no sensation is produced, on account of a disordered state of the part of the ganglionic centre in which the Optic nerve terminates, if the central tract which connects that nerve with the Third pair retain its integrity, the reflex contraction of the pupil may still be excited through it. The rarity of the occurrence is easily accounted-for, by the fact that in most cases of amaurosis the disease lies in the retina or in the trunk of the nerve, and thereby checks both its spinal and its encephalic actions.—Although we are not at present acquainted with any similar protective movements in the Human being, designed to keep the organ of Hearing from injury, yet there can be little doubt that those which we are constantly witnessing in other animals possessed of large external ears, are reflex actions excited by the irritation applied to them. In regard to the Nose, we find a remarkably complex action—that of Sneezing—adapted to drive-off any cause of irritation (§ 281). The stimulus is conveyed, in this case, not through the Olfactory nerve, but through the Fifth pair; so that it is not dependent upon the excitation of the sensation of Smell. The act of Coughing, also, may be regarded as of a protective character; being destined to remove sources of irritation from the air-passages. Many of the automatic movements performed by the limbs of Frogs and other animals, when their connection with the brain has been cut off, appear destined to remove these parts from sources of irritation or injury; and they may thus be rightly placed under the same category.

463. The fact that Sensation is very commonly *associated with* the reflex action we have been considering, being produced by the impression that excites them, has led many to suppose that it necessarily participates in them; a doctrine which we have seen to be untenable. But the question not unnaturally arises, *why* Sensation should so constantly participate in these operations, if not essential to them; and the answer to this question is to be found in the fact, that it is only through sensation that a higher set of actions, mental and bodily, is called into play, which is essential to the *continued maintenance* of those belonging to the present category. Illustrations of this truth might be drawn from any of the functions already noticed; but the ingestion of food will supply us with one of the most apposite. We have seen that the act of Deglutition is in itself independent of sensation; anything that comes within the grasp of the pharyngeal constrictors being conveyed downwards by their reflex contraction, just as anything which touches the arms of a Polype is entrapped by them and drawn into the stomach. But this action is attended with sensation, in the ordinary condition of the higher Animal, apparently in order that guidance may be thus afforded in the performance of those other movements of prehension, mastication, &c., by which the food may be brought within reach of the apparatus of deglutition; and the sensations which are linked with these are among the influences which prompt to those higher mental operations, whereby food is provided for the digestive apparatus to make use of. The Cœlenterate is dependent for its supplies of aliment upon what the currents in the surrounding fluid, or other chances, may bring into its neighbourhood; and if these should fail, it starves. The anencephalous Infant, again, can swallow, and even suck; but it can execute

no other movements adapted to obtain the supply of food continually necessary for its maintenance, because it has not a mind which sensations could awake into activity. The sensation connected with excito-motor actions has not only this important end, but it frequently contributes to enjoyment, as in Suction and in Emissio Seminis. The sensation accompanying the actions of this class, moreover, frequently affords premonition of danger, or gives excitement to supplementary actions destined to remove it, as in the case of Respiration; for where anything interferes with the due discharge of the function, the uneasy sensation that ensues occasions unwonted movements, which are more or less adapted to remove the impediment, in proportion as they are guided by judgment as well as by consciousness. Again, sensation often gives warning against inconvenience, as in the excretory functions; and here it is very evident, that its purpose is not only (if it be at all) to excite the associated muscles necesary for the excretion, but actually to make the Will set up the antagonizing action of the sphincters (§ 101).

464. We have now to inquire how far the independent action of the Spinal cord is concerned in the general muscular movements of Man, and especially in the locomotive actions of his inferior extremities. On this point, it is obvious that we must not be guided by the analogy of the lower animals; since the locomotive and other movements of Man are for the most part volitional and purposive, and he has to acquire by experience that control over his muscular apparatus which is necessary to enable him to perform them; whilst in Invertebrata generally, and in a large part of the lower Vertebrata, it is evident that the movements of progression, &c., which are characteristic of each species, come under the general category of automatic actions, and are provided for in the original organization of its nervous centres, being performed without any education, and under circumstances which render the notion of a purpose on the Animal's own part quite untenable. In so far as these instinctive movements require the guidance and direction of sensations, they must be referred to the 'consensual' group; but clear evidence is afforded by the continuance of many of them after the removal of the centres of sensation, that they are excito-motor in their character, and that they require no higher centre than the ganglia which correspond to the Spinal cord of Man.* There can be little doubt that the habitual movements of locomotion, and others which have become 'secondarily automatic,' may be performed by Man (under particular circumstances) through the agency of the Spinal cord alone, under the guidance and direction of the Sensorial centres, or even without such guidance; the required condition being, that the influence of the Cerebrum should be entirely withdrawn. Thus, numerous instances are on record, in which soldiers have continued to *march* in a sound sleep; and the Author has been assured by an intelligent witness, that he has seen a very accomplished pianist complete the performance of a piece of music in the same state.† A case has been mentioned to him by his friend Dr. William Budd, of a patient labouring under the form of epilepsy in which there was simply a temporary suspension of consciousness without convulsion, who, whenever the paroxysm came on, persisted in the kind of movement in which he was engaged at the moment; and thus on one occasion fell into the water through continuing to walk onwards, and frequently (being a

* See "Princ. of Comp. Phys.," §§ 649–654.

† In playing by memory on a musical instrument, the *muscular* sense often suggests the sequence of movements with more certainty than the *auditory;* and since the impressions derived from the muscles may prompt and regulate successional movements, without affecting the consciousness, there is no such improbability in the above statement as might at first sight appear.

shoemaker by trade) wounded his fingers with the awl in his hand, by a repetition of the movement by which he was endeavouring to pierce the leather. Such facts as these add great strength to the probability that when the Cerebral power is not suspended, but merely directed into another channel, as in the states of Reverie or Abstraction, and the attention is entirely drawn-off from the movements of locomotion, the continuance of these is due to the independent automatic action of the Spinal cord, the *direction* being given to them by the Sensory ganglia. This point, however, will be more fully considered hereafter; at present it may be remarked, that, when a regular train of movements is being performed under such conditions, every single action may be probably regarded as affording the stimulus to the next; each contact of the foot with the ground, in the act of walking, exciting the muscular contractions which constitute the next step;* and each movement of the musician prompting that which has customarily followed it, after the same fashion. Dr. Broadbent has called attention to an important law in reflex action, namely, that movements which are normally associated together, as for example, the contractions of the irides on exposure to light, are bilaterally co-ordinated in each centre.

465. Now in all these cases it seems reasonable to infer that the same kind of connection between the excitor and motor nerves comes to be formed by a process of gradual development, as originally exists in the nervous systems of those animals whose movements are entirely automatic; this portion of the nervous system of Man being so constituted, as to *grow-to* the mode in which it is habitually called into play. Such an idea is supported by all that we know of the formation and persistence of *habits* of nervo-muscular action. For it is a matter of universal experience that such habits are far more readily acquired during the periods of infancy, childhood, and youth, than they are after the attainment of adult age; and that, the earlier they are acquired, the more tenaciously are they retained. Now it is whilst the organism is growing most rapidly, and the greatest amount of new tissue is consequently being formed, that we should expect such new connections to be most readily established; and it is then, too, that the assimilative processes most readily take-on that new mode of action, which often becomes so completely a 'second nature,' as to keep up a certain acquired mode of nutrition through the whole subsequent life. It is an additional and most important confirmation of this view, to find that when a nerve-trunk has been cut across, the re-establishment of its conductive power which takes place after a certain interval is effected, not by the re-union of the divided fibres, but by the *development* of a new set of peripheral fibres in the place of the old ones (which undergo a gradual degeneration), this development proceeding from the point of section, and the central fibres remaining unaltered.†—That an actual continuity of nerve fibres, however, is not requisite for the establishment of those connections between excitor and motor nerves, in which the central organs take part, seems probable from the fact that under particular circumstances we find the influence of such impressions radiating in every direction, and extending to nerves which they do not ordinarily affect. Still there can be no doubt that the nerve-force is disposed to pass in special *tracks;* and it seems probable that while some of these are originally marked

* The truth of this view seems to the Author to be strongly supported by observation of the mode in which infants learn to walk; for it may often be observed that long before they can stand, they will instinctively perform the movements of walking, if they be so supported that the feet touch the ground.

† See Dr. Waller's important researches on the Reproduction of Nervous Substance, in Müller's "Archiv," 1852, Heft iv.

out for the automatic movements, others may be gradually worn-in (so to speak) by the habitual action of the Will; and that thus, when a train of sequential actions primarily directed by the Will has been once set in operation, it may continue without any further influence from that source.

466. Another manifestation of the independent power of the Spinal cord, is seen in its influence on *Muscular Tension.*—The various muscles of the body, even when there is the most complete absence of effort, maintain in the healthy state of the system a certain degree of firmness, by their antagonism with each other; and if any set of muscles be completely paralyzed, the opposing muscles will draw the part on which they act out of its position of repose; as is well seen in the distortion of the face which is characteristic of paralysis of the facial nerve on one side. This condition has been designated as the *tone* of the Muscles; but this term renders it liable to be confounded with their *tonic contraction*, which is also concerned in maintaining their firmness, but which is a manifestation of the simple contractility of their tissue, and is exhibited alike by the striated and the non-striated forms of muscular fibre, but more especially by the latter. On the other hand, the condition now alluded to, which may perhaps be appropriately termed their *tension*, is the result of a moderate though continued excitement of that contractility, through the nervous centres. It has been proved by Dr. M. Hall that the Muscular Tension is dependent, not upon the influence of the Brain, but upon that of the Spinal cord, as the following experiments demonstrate.—"Two Rabbits were taken; from one the head was removed; from the other also the head was removed, and the spinal marrow was cautiously destroyed with a sharp instrument: the limbs of the former retained a certain degree of firmness and elasticity; those of the second were perfectly lax."—Again: "The limbs and tail of a decapitated Turtle possessed a certain degree of firmness or tone, recoiled on being drawn from their position, and moved with energy on the application of a stimulus. On withdrawing the spinal marrow gently out of its canal, all these phenomena ceased. The limbs were no longer obedient to stimuli, and became perfectly flaccid, having lost all their resilience. The sphincter lost its circular form and contracted state, becoming lax, flaccid, and shapeless. The tail was flaccid, and unmoved on the application of stimuli."* It is further remarked by Messrs. Todd and Bowman, that "a decapitated frog will continue in the sitting posture through the influence of the spinal cord; but immediately this organ is removed the limbs fall apart."—This operation of the Spinal cord is doubtless but a peculiar manifestation of its ordinary reflex function. A curious experiment by M. Brown-Séquard† shows that this effect is not due to loss of contractility in the muscles; for although, after the division of the Spinal cord, there is a temporary diminution in their power, after a short interval the muscles when stimulated to contract will not only raise an equal but even a greater weight than before, the effect lasting in healthy frogs for 24 hours or more. Thus, two frogs, A and B, had weights fastened to the hind-legs until they were unable to raise them; the weighting amounted in each case to 925 grains. Immediately after divisionof the Cord they were able to raise—

	5 min. after.	15 min. after.	25 min. after.	1 hour after.	2 hours after.	4 hours after.	24 hours after.	48 hours after.
A, 308 grains.	694	925	1223	2003	2160	2160	2314	2314
B, 154 grains.	463	617	925	1540	1851	2003	2160	2160

* "Memoirs on the Nervous System," 1837, p. 93. † "Comptes Rendus," 1847.

We shall hereafter see how much the influence of the Will in producing the active contraction of a muscle is dependent upon sensations received from it; and it seems highly probable that the impression of the state of the muscle, conveyed by the afferent fibres proceeding from it to the Spinal cord, is sufficient to excite this state of moderate tension through the motor nerves arising from the latter. Such a view derives probability from the fact, which must have fallen under the observation of almost every one, that most reflex actions become increased in energy if resistance be made to them. Of this we have familiar examples in the action of the expulsor muscles which operate in defecation, urination, and parturition, if, when they are strongly excited, their efforts be opposed by spasmodic contraction of the sphincters, or by mechanical means. Many forms of convulsive movement exhibit the same tendency, their violence being proportional to the mechanical force used to restrain them. Here it is evident that the *impression of resistance* conveyed to the Spinal cord is the source of the increased energy of its motor influence; from which we may fairly infer that the moderate resistance occasioned by the natural antagonism of the muscles, is the source of their continued and moderate tension, whilst they are under the influence of the Spinal cord. This constant though gentle action serves to keep up the nutrition of the muscles which are paralysed to the will; and this is still more completely maintained, if the portion of the nervous centres with which they remain connected be so unduly irritable that the muscles are called into contraction upon the slightest excitation, and are thus continually exhibiting twitchings, startings, or more powerful convulsive movements. It is upon the continuance of the nutrition of the muscles that the persistence of their contractility depends; and hence the Spinal cord has an indirect influence upon this peculiar property, which is more likely to be retained when the muscle is still subject to the influence of the Spinal cord, though cut off from that of the Brain, than when it is completely paralysed by the entire severance of its connection with the nervous centres.

3. *Of the Sensory Ganglia and their Functions.—Consensual Movements.*

467. At the base of the Brain in Man, concealed by the Cerebral hemispheres, and connected with them through the mass of fibres known as the Corona radiata, but still readily distinguishable from them, we find the series of ganglionic masses which have been already mentioned as being in direct connection with the nerves of sensation, and which appear to have functions quite independent of those of the other components of the Encephalon. These are the olfactory and optic ganglia (Corpora quadrigemina), with the auditory and gustatory centres contained in the Medulla oblongata. The structure of the Corpora quadrigemina consists of nerve-cells, together with oblique, transverse, and longitudinal nerve-fibres resting on an arched transparent lamina, which forms the roof of the Sylvian Aqueduct.* A large portion of the optic tract is connected with the nates. The evidence obtained from anatomy, physiological experiment, and pathology, supports the view that the corpora quadrigemina, though not the centres of conscious vision, are centres of co-ordination of retinal impressions with special motor reactions.† After their removal, vision is completely abolished, and the pupils cease to act. Destruction of one optic lobe abolishes the vision of the opposite eye. In addition, destructive lesions of the Corpora quadrigemina

* Lockhart Clarke, "Proceedings of the Royal Society," June 20, 1861.

† See Ferrier, "The Functions of the Brain," 1876, p. 70.

cause disorders of equilibrium and defective co-ordination of the movements required for locomotion.* Electrical stimulation of the nates or posterior tubercle of one side causes the pupil of the opposite side, and then that of the same side, to become widely dilated. The eyeballs are directed upwards. The head is moved in the same direction as the eyeballs. There is retraction of the ears, and ultimately opisthotonos. Stimulation of the testis, or anterior tubercle, produces similar effects, with, in addition, cries. Dr. Ferrier regards them as the centres especially concerned in the reflex expression of feeling or emotion.—But besides these, at the base of the Cerebral hemispheres, we find two other large ganglionic masses on either side, through which nearly all the fibres appear to pass that connect the Hemispheres with the Medulla oblongata—namely, the *Thalami optici* and the *Corpora striata.* Now, although these are commonly regarded in the light of appendages merely to the Cerebral Hemispheres, it is evident from the large quantity of vesicular matter they contain, that they must rank as independent ganglionic centres; and this view is supported alike by the evidence of Comparative Anatomy, and by that afforded by the history of Development. For it is certain that the size of the Thalami optici and Corpora striata presents no more relation, in different tribes of animals, to that of the Cerebrum, than does that of the ganglia of Special Sense; and they may even present a considerable development, when the condition of the Cerebrum is quite rudimentary. Thus, in the Osseous fishes, a careful examination of the relations of the body, which is known as the Optic lobe makes it apparent that this is the representative, not merely of the proper Optic ganglion of Man, but also of the Thalamus opticus; whilst, again, the mass which is designated as the Cerebral lobe is chiefly homologous with the Corpus striatum of higher animals. The nature of the latter body is made apparent, in the higher Cartilaginous fishes, by the presence of a ventricle in its interior; the floor of this cavity being formed by the Corpus striatum, whilst the thin layer of nervous matter which forms its roof is the only representative of the Cerebral hemisphere. So in the Human embryo of the 6th week, we find a distinct vesicle for the Thalami optici, interposed between the vesicle of the Corpora quadrigemina and that which gives origin to the Cerebral hemispheres; whilst the Corpora striata constitute the floor of the cavity or ventricle which exists in the latter, this being as yet of comparatively small dimensions.—Now, as already pointed out (§ 445), we may distinguish in the Medulla oblongata and Crura cerebri, a *sensory* and a *motor* tract, by the endowments of the nerves which issue from them. The sensory tract may be traced upwards, until it almost entirely spreads itself through the substance of the Thalamus. Moreover, the Optic tracts and the peduncles of the Olfactory nerves may be shown to have a distinct connection with the Thalami, the former by the direct passage of a portion of their roots into these ganglia, and the latter through the medium of the Fornix. Electrical stimulation of one Corpus striatum and lenticular nucleus causes general convulsions of the muscles on the opposite side of the body without evidence of pain, whilst if these parts be destroyed, there is complete loss of voluntary power over the muscles of the opposite side of the body with preservation of the sensibility. Ferrier was unable in his experiments to detect any muscular movements on electrical stimulation of the Optic thalami. Hence we may fairly regard the *Thalami optici* as the chief focus of the *Sensory* nerves, and more especially as the ganglionic centre of the nerves of *common* sensation, which ascend

* See Serres, "Anatomie Comp. du Syst. Nerveux," 1827; McKendrick, "Trans. Roy. Soc. Edinb.," 1873; and Ferrier, loc. cit., p. 75.

to it from the Medulla oblongata and Spinal cord.—On the other hand, the *Corpora striata* are implanted on the *Motor* tract of the Crura cerebri, which descend into the Pyramidal columns; and their relation to the fibres of which that tract is composed, appears to be essentially the same as that which the Thalami bear to the sensory tract. The Corpora striata are connected with each other, on the median plane, by the *anterior* commissure; whilst the Thalami optici are united by the *soft* and the *posterior* commissures. The Corpus striatum and Thalamus opticus of the same side are very closely connected by commissural fibres, stretching from one to the other; and, if the preceding account of the respective offices of these bodies be correct, they may be regarded as having much the same relation to each other as that which exists between the posterior and anterior peaks of vesicular matter in the Spinal cord;* the latter issuing motor impulses in respondence to sensations excited through the former. They are also intimately connected with other ganglionic masses in their neighbourhood, such as the 'locus niger,' and the vesicular matter of the 'tuber annulare;' which, again, are in close relation with the vesicular matter of the Medulla oblongata.

468. It has been commonly supposed that the fibres of the Crura cerebri, after entering the Corpora striata and Thalami optici, pass continuously through these bodies, receiving 'reinforcements' of additional fibres from their ganglionic matter; and that they then radiate to the internal surface of the grey matter of the Cerebral hemispheres. Such would certainly be the conclusion to which a superficial examination of their course would lead. But very strong reasons exist for the belief that the fibres of the Crura cerebri for the most part terminate in the vesicular substance of the Corpora striata and Thalami optici; and that the radiating fibres of the Hemispheres take a fresh departure from these ganglia, serving, in fact, the part of commissures to connect *their* vesicular substance with that of the Cerebral ganglia.† And this view, as we shall hereafter see, is in complete accordance with the existence of a very decided *physiological* separation between these two sets of organs. A different view is proposed by others, according to which the motor fibres forming the corona radiata,‡ are divisible into two groups, the fibres of one of which are the channel of involuntary movements, and, after traversing the Optic thalami and Corpora quadrigemina, descend in the tegmentum of the crus cerebri without decussating till they have reached the Spinal cord, in the grey matter of which they cross and issue with the anterior roots. The other group is the channel for voluntary movements. The fibres pass from the cortex cerebri to the corpus striatum and lenticular nucleus, and, descending in the pes of the crus cerebri, form the decussation of the anterior pyramid. Still another view has lately been propounded by Flechsig,§ to the effect that the pyramids of the Medulla oblongata traverse the pons, the pes or basis of the crus cerebri, and the internal capsule without being interrupted by the presence of any ganglion cells till they reach the cortex cerebri; the fibres forming these columns would probably be the conductors of voluntary impulses.—Altogether it is very evident that a series of true ganglionic centres exist at the base of the Encephalon, which are really as distinct from either the Cerebrum or Cerebellum as the latter are from each other; and as these centres are in immediate connection with the nerves both of *special* and

* This was first pointed-out by Messrs. Todd and Bowman, in their "Physiological Anatomy," vol. i. pp. 347–350.

† See especially Messrs. Todd and Bowman's "Physiological Anatomy," vol. i. p. 277 and Prof. Kölliker's "Mikroskopische Anatomie," Band ii. § 118.

‡ Hermann, "Handbuch," vol. i. p. 304.

§ "Centralblatt f. d. Med. Wiss.," 1877, pp. 35, 614.

of *general* Sense, they may be appropriately designated the *Sensory Ganglia*. —An inquiry into the distribution and endowments of their nerves will assist us in the determination of the functions of the central organs in which they terminate.

469. *Nerves of Special Sense.*—Through the First pair, or *Olfactory* nerve, the roots of which have been traced to the cortex of the *gyrus uncinatus*, to the frontal portion of the *gyrus fornicatus*, and to the *corpus striatum*, are transmitted the impressions made by odorous emanations upon the surface it supplies; and it is not susceptible to impressions of any other kind. Anatomical examination of the distribution of this nerve proves that it is not one which directly conveys motor influence to any muscles, since all its branches are distributed to the membrane lining the nasal cavity; and experimental inquiry leads to the same result, for no irritation of the peduncles or branches excites any muscular movement. Further, no irritation of any part of this nerve excites reflex actions through other nerves. Again, it is not a nerve of 'common' sensation; for animals exhibit no signs of pain when it is subjected to any kind of irritation. Neither the division of the nerve, nor the destruction of the olfactive ganglia, seems to inconvenience them materially. They take their food, move with their accustomed agility, and exhibit the usual appetites of their kind. The 'common' sensibility of the parts contained in the olfactive organ is in no degree impaired, as is shown by the effect of irritating vapours; but the animals are destitute of the sense of smell, as is shown by the way in which these vapours affect them; for at first they appear indifferent to their presence, and then suddenly and vehemently avoid them as soon as the Schneiderian membrane becomes irritated. Moreover, if two dogs, with the eyes bandaged, one having the olfactory nerves and ganglia sound, and the other having had them destroyed, are brought into the neighbourhood of the dead body of an animal, the former will examine it by its smell; whilst the latter, even if he touches it, pays no attention to it. This experiment Valentin* states he has repeated several times, and always with the same results. Further, common observation shows that *sensibility to irritants*, such as snuff, and *acuteness of smell*, bear no constant proportion to one another; and there is ample pathological evidence, that the want of this sense is connected with some morbid condition of the olfactory nerves or ganglia.—It is well known that Magendie has maintained, that the Fifth pair in some way furnishes conditions requisite for the exercise of the power of smell; asserting that, when it is cut, the animal is deprived of this sense. But his experiments were made with irritating vapours, which excite sternutation or other violent muscular actions, not through the Olfactory nerve but through the Fifth pair; and the experiments of Valentin, just related, fully prove that the animals are not sensitive to *odours*, strictly so called, after the Olfactory nerve has been divided. The acuteness of the true sense of smell is lessened by section of the Fifth pair; but this is because the Schneiderian membrane is then no longer duly moistened by its proper secretion, and when dry it is less susceptible of the impressions made by those minute particles of odoriferous substances, to which the excitement of the sensation must be referred. A number of cases have, however, been collected by Claude Bernard, and especially a well-authenticated one (Marie Lemmens), in which, whilst no failure of the sense of smell was observed during life, the complete absence of the olfactory nerve was ascertained on post mortem examination.

470. That the Second pair, or *Optic* nerve, has an analogous character, appears alike from anatomical and experimental evidence. The roots of this

* "De Functionibus Nervorum Cerebralium," &c., Bernæ, 1839.

nerve may be traced to the *stratum zonale* and posterior part of the *optic thalamus*, to the *corpus geniculatum externum*, and perhaps also to the internum and to the *nates* or anterior pair of the corpora quadrigemina. The cortical cerebral centre is situated at the apex of the occipital lobe. No chemical or mechanical stimulus of the trunk produces *direct* muscular motion; nor does it give rise, so far as can be ascertained, to indications of pain; whence it may be concluded that this nerve is not one of 'common' sensation. That the ordinary sensibility of the eyeball remains, when the functions of the Optic nerve are completely destroyed, is well known; as is also the fact, that division of it puts an end to the power of vision. Valentin states that, although the Optic nerve may, like other nerves, be in appearance completely regenerated, he has never been able to obtain any evidence that the power of sight has been in the least degree recovered. He remarks that animals suddenly made blind exhibit great mental disturbance, and perform many unaccustomed movements; and that the complete absence of the power of vision is easily ascertained. Morbid changes are sometimes observed to take place in eyes whose Optic nerve has been divided; but these are by no means so constant or so extensive as when the Fifth pair is paralyzed; and they may not improbably be attributed to the injury occasioned by the operation itself to the parts within the orbit.

471. The Optic nerve, though analogous to the Olfactory in all the points hitherto mentioned, differs from it in one important respect—that it has the power of conveying impressions which excite *reflex* muscular motions. This is especially the case in regard to the Iris, the ordinary actions of which are regulated by the degree of light impinging on the retina. The fibres of the optic nerve that reflectorially excite the branches of the third nerve distributed to the Iris undergo partial or complete decussation in the chiasma optici.* When the Optic nerve is divided, contraction of the pupil takes place; but this does not occur if the connection of this nerve with the third pair, through the nervous centres, be in any way interrupted. After such division (if complete), the state of the pupil is not affected by variations in the degree of light impinging on the retina; except in particular cases, in which it is influenced through other channels. Thus, in a patient suffering under amaurosis of one eye, the pupil of the affected eye is often found to vary in size, in accordance with that of the other eye; but this effect is due to the action of light on the retina of the sound eye, which produces a motor change in the third pair on both sides. Further, as already shown (§ 462), the *impression* only of light upon the retina may give rise to contraction of the pupil, by reflex action, when the Optic nerve is itself sound; whilst no *sensations* are received through the eye, in consequence of disease in the sensorial portion of the nervous centres. Although the contraction of the pupil is effected by the influence of motor fibres which proceed to the sphincter of the Iris from the third pair of nerves, *through* the Ophthalmic ganglion (its dilatation, as we shall hereafter see) depends upon the influence it derives from the Sympathetic system, of which that ganglion forms part.—Besides the contraction of the pupil, another action of a 'reflex' character is produced through the Optic nerve—namely, the contraction of the Orbicularis muscle under the influence of strong light, or when a foreign body is suddenly brought near the eye. But this cannot be excited without a consciousness of the visual impression; in fact, it is a movement of a 'consensual' kind, produced by the painful sensation of light, which gives rise to the condition well characterized by the term *photophobia*.

* See Knoll, "Centralblatt," 1372, p. 265.

The involuntary character of it must be evident to every one who has been engaged in the treatment of diseases of the eyes; and the effect of it is aided by a similarly involuntary movement of the eyeball itself, which is rotated upwards and inwards, to a greater extent than the Will appears able to effect. —Another reflex movement excited through the visual sense is that of Sneezing, which is induced in many individuals by the sudden exposure of the eyes to a strong light: of the purely autonomic character of this movement there can be no question, since it cannot be imitated voluntarily; and that it is not excito-motor is proved by the fact that it is not excited unless the light be *seen.**

472. There is a further peculiarity, of a very marked kind, attending the course of the Optic nerves; this is the crossing or 'decussation' which they undergo more or less completely, whilst passing between their ganglia and the eyes. In some of the lower animals, in which the two eyes (from their lateral position) have entirely different spheres of vision, the decussation is complete; the whole of the fibres from the right optic ganglion passing into the left eye, and *vice versâ*. This is the case, for example, with most of the Osseous Fishes (as the cod, halibut, &c.); and also, in great part at least, with Birds.† In the Human subject, however, and in animals which, like him, have the axes of both eyes directed to the same object, the view entertained by many excellent anatomists and microscopists up to a recent period was that suggested by Hannover‡—namely, that the *posterior* border of the Optic Chiasma is formed exclusively of *commissural* fibres, which pass from one *optic ganglion* to the other, without entering the real optic nerve; whilst the *anterior* border of the Chiasma is composed of fibres, which seem, in like manner, to act as a commissure between the two *retinæ;* passing from one to the other, without any connection with the optic ganglia. The tract which lies between the two borders, and occupies the *middle* of the Chiasma, Hannover considers to be the true Optic Nerve; and in this he thought that a portion of the fibres decussates, whilst another portion passes directly from each Optic ganglion into the corresponding eye. The fibres proceeding from the ganglia to the retinæ, constituting the proper Optic Nerves, he distinguished into an internal and an external tract. Of these the *external*, on each side, he maintained, passes directly onwards to the eye of *that* side: whilst the *internal* crosses over to the eye of the *opposite* side. The distribution of these two sets of fibres in the retina of each eye respectively, would thus be such that, as Mayo concluded, the fibres from either optic ganglion is distributed to *its own side* of *both* eyes; the right optic ganglion being thus exclusively connected with the outer part of the retina of the right eye, and with the inner part of the retina of the left; whilst the left optic ganglion is connected exclusively with the outer side of the left retina, and with the inner side of the right. Now as either side of the eye receives the images of objects which are on the other side of its axis, it follows, if this account of the distribution of the nerves be correct, that in Man, as in the lower animals, each ganglion receives the impressions of objects situated on the *opposite* side of the body. This view is supported by the fact that extirpation of one eye in Man, as well as in Dogs and Cats (Baumgarten, Gudden), one half of both optic nerves atrophy; and it has also been shown that an antero-posterior section of the Chiasma in Cats is only followed by

* A patient was for some time in the London Hospital, in whom there was such an undue impressibility of the retina, that she could not remain in even a moderate light without a continual repetition of the act of Sneezing.

† See Solly on "The Human Brain," 2nd edit., p. 288. ‡ "Das Auge," 1852.

partial blindness. It is equally certain that varieties exist in regard to the decussation of the optic nerves in both man and animals; for other researches* seem to prove that the *decussation of the optic nerves is sometimes complete in Man*, though the fibres pursue a wavy course, which might readily lead to the assumption of the existence of the commissures and tracts above mentioned. In accordance with this is the observation of M. Brown-Séquard† that section of one optic tract causes complete amaurosis of the opposite eye, whilst an antero-posterior section of the Chiasma produces complete blindness of both eyes. A few rare cases have also been recorded in Man in which no decussation existed, so that the right optic tract became the right optic nerve, and *vice versâ*, with good vision.‡ It is possible, of course, that in such cases the decussation may have taken place in the brain. Cases have also been observed in Man in which disease of one optic tract has been accompanied by failure of vision in the corresponding upper (lower) union or outer parts of both retinæ, which necessitates a different distribution of the fibres. Where the decussation exists, its purpose may be to bring the visual impressions, which are so important in directing the movements of the body, into proper harmony with the motor apparatus; so that the decussation of the motor fibres in the pyramids being accompanied by a decussation of the optic nerves, the same effect is produced as if neither decussated—which last is the case with Invertebrate animals in general. The view maintained by Hannover receives some support from the interesting observation of Towne, that a blending of two colours occurs if their images are simultaneously presented to the *inner* side of one retina and the *outer* side of the other retina, but not otherwise.§

473. The functions of the *Auditory* nerve, or *Portio Mollis* of the Seventh, are easily determined, by anatomical examination of its distribution, and by observation of pathological phenomena, to be analogous to those of the two preceding. This nerve arises from two nuclei, the cells of which communicate. (Figs. 220, 221.) They are situated in the floor of the Fourth ventricle, at its broadest part. The anterior nucleus, which is specially connected with the Portio intermedia Wrisbergii,‖ appears to contain vaso-motor fibres. Part of the fibres arising from it runs to the cerebellum in its middle peduncle. The white striæ medullares seen on the floor of the Fourth ventricle run to the opposite pedunculus cerebelli; and some fibres, though their exact course is not known, run in the cerebral peduncle and extend to an acoustic centre in the occipital region of the cortex cerebri. Atrophy or lesion of the trunk destroys the sense of Hearing; whilst irritation of it produces auditory sensations, but does not occasion pain. From experiments made upon the nerve before it leaves the cranial cavity, it appears satisfactorily ascertained that this nerve is not endowed either with common sensibility or with the power of directly stimulating muscular movement. Nor can any obvious reflex actions be induced by stimulation of this nerve; but it seems nevertheless by no means improbable, that the muscles which regulate the tension of the Tympanum are called into action by impressions made upon it and reflected through the auditory ganglion, in the same manner as the diameter of the pupil is regulated through the optic nerve. In the involuntary start, however, which is

* Biesiadecki, "Wien. Akad. Sitz.-ber.," Band xlii., 1861, p. 86. Mandelstamm, "Centralblatt f. d. Med. Wiss., 1873, No. 22. Michel, "Archiv f. Ophthalmol.," Band xix. Heft 2, 1873.

† Brown-Séquard, "Archives de Physiologie," 1872, p. 261. ‡ Vesalius. Caldani. Lösel.

§ For additional facts bearing on this subject, see the observations of Mr. Towne 'On the Stereoscope and Stereoscopic Results,' in "Guy's Hospital Reports" for 1862, p. 69, and 1863 p. 103. ‖ Landois, "Physiologie," 1880, p. 681.

occasioned by a loud and sudden sound, we have an example of a *consensual* movement excited through the Auditory nerve, which is evidently analogous to the closure of the eyes to a strong light. In certain morbidly-impressible states of the nervous system, as will be presently shown, the effect of sounds on the motor apparatus is far more remarkable.—It has been attempted by Flourens to show that the portion of the Auditory nerve which proceeds to the Semicircular canals has functions altogether different from that portion which supplies the Vestibule and Cochlea, and that it plays an important part in the maintenance of the equilibrium of the body, a subject that will be subsequently discussed.

474. The nerves which minister to the sense of *Taste* are destitute of the peculiarities which distinguish the preceding; being no other than certain branches of ordinary afferent nerves,—the Fifth Pair and Glosso-pharyngeal (§§ 447–450)—the peculiar endowments of which seem to depend rather upon the structure and actions of the papillæ at their peripheral extremities, than upon anything special in their own character; for, as in the case of the ordinary nerves of 'common' sensation, mechanical irritation applied to them calls-forth indications of pain.—From the observations and experiments of M. Cl. Bernard and others,* it appears that the Facial nerve (portio dura of the Seventh) supplies some condition requisite for the sense of Taste, through the branch known as the Chorda tympani, which is the motor nerve of the Lingualis muscle and Sub-maxillary gland (§ 105). When paralysis of the Facial exists in Man, the sense of taste is very much impaired on the corresponding side of the tongue, provided that the cause of the paralysis be seated above the origin of the Chorda tympani from its trunk. Similar results have been obtained from experiments upon other animals. The effect may possibly be attributable to an interference with the secretion of saliva.

475. *Nerves of Common Sensation.*—To the sense of *Touch* all the afferent nerves of the body (save the nerves of special sense) appear to minister; in virtue—according to the doctrine already propounded—of the direct connection of certain of their fibrils with the *Sensorium Commune.* But the degree in which they are capable of producing Sensations does not bear any constant relation to their power of exciting reflex actions. Thus, the Glosso-pharyngeal is not nearly so *sensitive* as the Fifth pair; though more powerful as an *excitor* nerve. The Vagus appears to have even less power of arousing sensory changes; although it is the most important of all the excitors to reflex action. So, again, the afferent nerves of the inferior extremities, in Man, are less concerned in ministering to sensations, than are those of the superior; and yet they appear to be much more efficient as excitors to muscular movement.—These differences may be accounted for, by supposing that the proportion which the fibres having their centre in the ganglionic matter of the Spinal Cord, bears to that of the fibres which pass on to the Sensorium, is not constant, but is liable to variation in different nerves; the former predominating in the Vagus and the Glosso-pharyngeal, whilst the latter are more numerous in the Fifth Pair, and in most of the Spinal nerves.

476. *Motor Nerves.*—No motor nerves issue from the Sensory Ganglia with the same directness that afferent nerves proceed towards them; but the reflex actions of these centres find a ready channel in the motor nerves of the Cranio-Spinal axis generally. For, as we have seen (§ 445), the motor tract of the Crura cerebri, which is in connection with the motor Encephalic nerves, and

* "Archives Générales de Médecine," 1844. See also Lussana, Neumann, Roux, Juzani, and Baragiola.

also (through the vesicular substance of the Spinal cord) with the anterior roots of the Spinal nerves, passes up into the Corpora striata and Corpora quadrigemina. Although the direct connection of the other ganglia of Special Sense with the Motor columns is at present a matter of presumption only, yet this presumption is strongly supported by the analogy of the Optic ganglia; the distinctness of this connection in *their* case being easily accounted for, when it is remembered in how great a degree the general movements of the body are guided by the visual sense.

477. *Functions of the Sensory Ganglia.*—We have now to consider what deductions may be drawn with regard to the functions of the Sensory ganglia in Man, from the facts supplied by Comparative Anatomy, by Experimental inquiry, and by Pathological phenomena. The determination of these functions may seem to be the more difficult, as it is impossible to make any satisfactory experiments upon the ganglionic centres in question, by isolating them completely from the Cerebral hemispheres above, and from the Medulla oblongata and Spinal cord below. But the evidence derived from Comparative Anatomy appears to be in this case particularly clear; and, rightly considered, affords us nearly all the information we require. In the series of "experiments prepared for us by Nature," which is presented to us in the descending scale of animal life, we witness the effects of the gradual change in the relative development of the Sensory ganglia and Cerebral hemispheres, which are presented to us in descending through the Vertebrate scale; and the results of the entire withdrawal of the latter, and of the sole operation of the former, which are exhibited in the higher Invertebrata (see §§ 447, 450),* and we are thus led by the very cogent evidence which Comparative Anatomy supplies, to regard this series of Ganglionic centres as constituting the real *Sensorium;* each ganglion having the power of rendering the Mind conscious of the impressions derived from the organ with which it is connected. If this position be denied, we must either refuse the attribute of consciousness to such animals as possess no other Encephalic centres than these; or we must believe that the *addition* of the Cerebral hemispheres, in the Vertebrate series, *alters* the endowments of the Sensory ganglia—an idea which is contrary to all analogy.

478. So far as the results of Experiments can be relied on, they afford a corroboration of this view. The degree in which animals high in the scale of organization can perform the functions of life, without any other centres of action than the Ganglia of Special Sense, the Medulla oblongata, and the Cerebellum, appears extraordinary to those who are accustomed to regard the Cerebral hemispheres as the centre of all energy. Not only Reptiles, but Birds and Mammals, may survive for many weeks or even months (if their physical wants be duly supplied) after the removal of the entire Cerebrum.† It is difficult to substantiate the existence in them of actual *sensation;* but

* It is worthy of special notice, that the development of the Cephalic ganglia in the Invertebrata always bears an exact proportion to the development of the *eyes;* the other organs of special sense being comparatively undeveloped; whilst these, in all the higher classes at least, are instruments of great perfection, and are evidently connected most intimately with the direction of the movements of the animals. Of this fact we have a remarkable illustration in the history of the metamorphosis of Insects; the eyes being almost rudimentary, and the Cephalic ganglia comparatively small, in most Larvæ; whilst both these organs attain a high development in the Imago, to whose actions the faculty of sight is essential.

† Flourens, "Récherches Expérimentales sur les Propriétés et les Fonctions du Système Nerveux," 2nd edit., 1845. Hertwig, "Exper. de effect. læsion. in partibus Encephali," Berol., 1826. Magendie, "Leçons sur les Fonctions du Système Nerveux," Paris, 1839. Longet, "Traité de Physiologie," tom ii. partie 2, 1860, p. 411.

some of their movements appear to be of a higher kind than those resulting from mere excito-motor action. So long as the animal is kept at perfect rest, and not excited by any stimulus, tactile or otherwise, so long does it remain quiet and immovable. It is only when stimulated that it begins to move. One of the most remarkable phenomena exhibited by such a being, is the power of maintaining its equilibrium, which can scarcely exist without consciousness.* If it be laid upon the back, it rises again: if pushed, it walks. If a Bird thus mutilated be thrown into the air, it flies; if a Frog be touched, it leaps; if thrown into the water it swims. It swallows food and liquid, when they are placed in its mouth; and the digestive operations, the acts of excretion, &c., take place as usual. If the back or interscapular region be touched it croaks.† Frogs without Cerebrum, Optic thalami or Optic lobes no longer croak on stroking the back, and lose the power of maintaining their equilibrium when the board on which they are placed is slowly inclined. In the case of a Pigeon experimented on by Malacorps, which is recorded by Magendie, there appears sufficient proof of the persistence of a certain amount of sensation. Although the animal was not affected by a strong light suddenly made to fall upon its eyes, it was accustomed, when confined in a darkened or partially-illuminated room, to seek out the light parts; and *it avoided objects that lay in its way.* In the same manner, it did not seem to be affected by sudden noises; but at night, when it slept with its eyes closed and its head under its wing, it would raise its head in a remarkable manner, and open its eyes, on the slightest noise; speedily relapsing into a state of complete unconsciousness. Its principal occupation was to preen its feathers and scratch itself. And Longet mentions that a Pigeon from which he had removed the entire Cerebrum, gave many indications of consciousness of light; for not only did the pupil contract, but the lids closed, when a strong light was suddenly made to fall upon the eye, the animal having been previously kept in darkness; and *when a lighted candle was made to move in a circle before it, the animal executed a corresponding movement with its head.*‡—The condition of such beings seems to resemble that of a Man, who is in a slumber sufficiently deep to lose all distinct *perception* of external objects, but who is yet conscious of *sensations*, as appears from the movements occasioned by lights or by sounds, or from those which he executes to withdraw the body from an uneasy position.

479. The results of other experiments made upon the Sensory ganglia themselves, and upon the organs from which they derive their impressions, confirm this view; by showing that the ordinary movements are seriously perturbed, and that in some instances a new set of automatic movements is induced, when the normal relations between the sensory and motor apparatus are disarranged. Of the functions of the ganglia of special sense, those of the *Corpora Quadrigemina* are the chief which have been examined experimentally. These ganglia are connected with the *motor* columns of the spinal cord on each side by a strand of fibres thrust aside by the decussation

* Eckhard "Handbuch der Physiologie," Band i. 1879, p. 117.

‡ It must not be forgotten that, in such experiments, the severity of the operation will of itself occasion a suspension or disturbance of the functions of parts that remain; so that the *loss* of a power must not be at once inferred from the absence of its manifestations. But the *persistence* of a power, after the removal of a particular organ, is a clear proof that it cannot be the peculiar attribute of that organ. See Voit's experiments on Pigeons, which, after removal of the hemispheres, recovered sufficiently to perform all their ordinary acts except that of feeding themselves. "Sitzungsber. der Bair Acad. Math. Phys. Cl." 1868.

of the pyramids, which, passing upwards and embracing the olivary body, ascends through the pons, and enters the lateral and posterior part of the testes. The decussation of some of the fibres of these strands forms the roof of the aqueduct of Sylvius. They are connected with the sensory *columns* of the cord through the tegmentum and the Optic thalami. It is probable that fibres of both optic tracts arise* from them. The experiments of Flourens and Hertwig have shown that the connection of these bodies with the visual function, which might be inferred from their anatomical relations, is substantiated. The partial loss of the ganglion on one side produces partial loss of power and temporary blindness on the opposite side of the body, without necessarily destroying the mobility of the pupil; but the removal of the larger portion, or complete extirpation of it, occasions permanent blindness and immobility of the pupil, with temporary defect of the power of co-ordinating muscular movements on the opposite side. This temporary disorder of the muscular system sometimes manifests itself in a tendency to rotation, as if the animal were giddy; but no disturbance of consciousness appears to be produced; and Hertwig states that he never witnessed the convulsions, which Flourens mentions as a consequence of the operation, and which were probably occasioned by his incision having been carried too deeply. As Longet has justly remarked, it is difficult, if not impossible, to remove one or both of these ganglionic masses, without doing such an injury to the Crura cerebri on which they repose, as shall in great degree account for such disturbed movements (§ 483). Irritation of *one* of the Corpora quadrigemina has been observed, both by Flourens and Longet, to produce contraction of the pupils of *both* eyes. Budge has corroborated Flourens' statements, adding that it is only when the lesion affects the inner part of the Corpora quadrigemina, that paralysis of the Iris occurs, and that this paralysis is on the side opposite to the lesion. Renzi admits there is temporary, but denies that there is any permanent, loss of contractility of the Iris. Knoll† found that irritation of one of the Nates caused dilatation of both pupils, but especially of that of the same side, and that lesions of the corpora quadrigemina were without effect on the iris, as long as the optic tracts were untouched; but when these were damaged between the corpora quadrigemina and the chiasma, blindness with paralysis of the opposite iris occurred. Lesions of the optic nerve on the distal side of the chiasma caused paralysis of the Iris of the same side, showing that the fibres of the optic nerve which excite reflectorially the iridal branches of the third nerve, undergo complete decussation in the chiasma. Irritation of the right anterior Corpus, first causes both eyes and then the head to turn to the left, and *vice versâ*. Ferrier found that in rabbits a slight puncture caused the animal to start suddenly and bound away as if alarmed. Electrical stimulation caused retraction of the ears, elevation of the tail, extension of the jaws, clenching of the teeth, and on increasing the strength of the stimulus, opisthotonos. Brunton noticed in Birds increase of the blood pressure, prolongation of the cardiac beats, and deeper respiration. Knoll, operating on Rabbits, did not observe any alteration in their motility after injuries inflicted upon these bodies, but other observers‡ have shown that the optic lobes in Frogs and in Birds, and the corpora quadrigemina in Mammals, exert a powerful influence in effecting the harmony and co-ordination of muscular movements and in maintaining the equilibrium of the body. The results of experiments are partly confirmed by Pathological phenomena in Man; for there are many

† "Centralblatt f. d. Med. Wiss.," 1872, p. 265.

‡ Cayrade, "Journ. de l'Anat.," 1868; McKendrick, loc. cit.; Ferrier, loc. cit.

instances on record in which blindness has been one of the consequences of disease in one or both tubercles; and in some of the cases in which the lesion extended to parts seated beneath the tubercles, disturbed movements were observed.—The subservience of these bodies to the exercise of the visual sense, appears, on the whole, to be the point best established in regard to their functions; and considering the degree in which this sense is concerned in the regulation of the general movements of the body, it is not surprising that lesions of its centre should occasion a perversion of these movements. This appears the more probable from the fact, that in animals whose Sensory ganglia bear so large a proportion to the whole Encephalon, that we must look upon them as the principal centres of motor activity, instead of being chiefly concerned (as in Man) in the mere guidance of movements whose origin is Cerebral, lesions of the organ of sense from which the impressions that excite the sensori-motor impulses are derived, produce a corresponding disturbance. Thus Flourens found that a vertiginous movement may be induced in Pigeons by simply blinding one eye; and Longet produced the same effect by evacuating the humours of the eye.

480. It is probably on the same principle that we are to account for the remarkable results obtained by Flourens* from section of the portion of the Auditory nerve proceeding to the semicircular canals. Section of the horizontal semicircular canal in Pigeons, on both sides, induces a rapid jerking horizontal movement of the head, from side to side; and a tendency to turn to one side which manifests itself whenever the animal attempts to walk forwards. Section of a vertical canal, whether the superior or inferior, of both sides, is followed by a violent vertical movement of the head. And section of the horizontal and vertical canals, at the same time, causes horizontal and vertical movements. Section of either canal on one side only, is followed by the same effect as when the canal is divided on both sides; but this is inferior in intensity. The movements continue to be performed during several months, but cease immediately if the Thalami optici be removed (Löwenberg). In Rabbits, section of the horizontal canal is followed by the same movements as are exhibited by Pigeons; and they are even more constant though less violent. Section of the anterior vertical canal causes the animal to make continued forward 'somersets;' while section of the posterior vertical canal occasions continued backward 'somersets.' The movements cease when the animal is in repose; and they recommence when it begins to move, increasing in violence as its motion is more rapid.—These curious results are supposed by M. Flourens to indicate that the nerve supplying the semicircular canals does not minister to the sense of hearing, but to the direction of the movements of the animal; whilst M. Cyon† refers them to the circumstance that in order that an animal should preserve its equilibrium, it should have a correct idea of the position of its own head, and that the semicircular canals supply this information in consequence of each canal having a definite relation to space. But they may also be explained upon the supposition, that the normal functions of the semicircular canals is to indicate to the animal the *direction* of sounds, and that its movements are partly determined by these; so that a destruction of one or other of them will produce an irregularity of movement (resulting, as it would seem, from a sort of giddiness on the part of the animal), just as when one of the eyes of the bird is covered or destroyed, as in the experiments previously cited. Goltz‡ has recently maintained that

* Op. cit. See also Böttcher, "Centralblatt f. d. Med. Wiss.," 1873, p. 72; and Löwenberg, idem, p. 278; Waldeyer, idem, 1872, p. 385.

† Pflüger's "Archiv," Band viii. p. 325. ‡ Ibid., Band iii. 1870, p. 172.

the position of the head is judged of by the animal from the pressure exerted by the endo-lymph on one side or the other of the semicircular canals; and that when the endo-lymph has escaped by section of the canals, neither the eye nor the muscular sense can supply the deficiency—the movements of the body are on this view secondary, and are due to the inability of the animal to judge of its relation to surrounding objects from the position of its head; on the other hand, a definite perception of the position of the head may be necessary to the maintenance of equilibrium; and this perception has its origin in the semicircular canals, each canal having a certain determinate relation to certain positions.* The derangement of motion consequent upon division of the semicircular canals, Cyon classifies under three heads:—1. Derangements of equilibrium, as a direct result of the injury. 2. Violent movements, resulting from the irritation consequent on the abnormal sense of hearing induced thereby. 3. Consecutive symptoms, occurring some days after the operation, from the resulting inflammation of the cerebellum.

481. The numerous experiments which have been made for the purpose of determining the functions of the Thalami optici and Corpora striata, have not yielded any very satisfactory results; chiefly on account of the impossibility of completely isolating them in such a manner as to limit the operation (whether this be section, removal, or irritation) to them alone. Thus it is impossible to remove them, either separately, or conjointly, without first removing the Cerebral hemispheres; and the Thalami cannot be entirely removed without dividing the stratum of fibres which traverse their deeper portion in their passage to the Corpora striata. The relations of the Thalami optici to the *visual sense* are not certainly known; for (according to the affirmation of Longet) they may be completely destroyed in Mammals and Birds, without destruction of sight or loss of the activity of the iris; whilst irritation of one or both of them produces no contraction of the iris. Renzi,† however, found that removal of the posterior part of the Optic thalamus of one side was followed by blindness and permanent dilatation of the pupil of the opposite eye, whilst Lussana and others have observed blindness of the opposite eye in cases of injury of the Thalamus in which the optic tracts and the adjoining region of the Thalamus had not been damaged. Hughlings Jackson has recorded a case in which lesion of the posterior part of the Optic thalamus was associated during life with left-sided hemiopia of both eyes. The loss of sight with dilatation and immobility of the pupil, which is frequently observed in cases of apoplectic effusions into the substance of the Thalami, may no doubt be sometimes due to the compression of the Optic nerves which lie beneath them; but there seems good reason to believe that the Thalami really constitute centres for visual impressions, since animals still clearly retain a certain amount of vision after the removal of the whole of both hemispheres. Evidence also exists to show that they have some relation to the other special senses; for although these are to some extent retained after the removal of the Optic thalami, yet there are many pathological cases showing impairment of the tactile and auditory senses with lesion of their substance. These bodies appear to possess a very decided influence on the power of *voluntary movement;* for although an animal maintains its balance, and can be made to move onwards, after the removal of the Cerebral hemispheres, and even after the removal of the Corpora striata, yet if either of the Thalami optici be removed, the sensibility and power of voluntary movement are destroyed on the *opposite* side of the body, and the animal

* See also Abstract, Knapp's "Archives of Ophth. and Otol.," 1874, p. 137.

† "Annali Universale," vol. clxxxix. p. 419.

consequently falls over to that side (Longet). If incisions equal in depth and direction be made simultaneously into certain parts of the Optic thalamus of each side in frogs from which the brain has been removed, an uncontrollable impulse to move forwards is observed; but if the incisions be not symmetrical the animal keeps turning to one side in a circular manner (*évolution du manége*): according to Longet and Lafargue, this movement is directed in the rabbit towards the opposite side; whilst Flourens states that in the frog its direction is towards the injured side; and according to Schiff* the destruction of the three anterior fourths of this organ in the rabbit determines this movement towards the injured side, whilst that of the posterior fourth determines the movement towards the opposite side. Brown-Séquard attributes the rolling movements in many of these cases to certain muscles being in a state of spasm, in other instances to vertigo. Both Schiff and Lancerotte† regard the Optic thalamus as containing a centre for the fore limb. Nothnagel‡ entirely destroyed both Thalami in rabbits without removal of the Cerebrum, and declares that they only differed from uninjured animals in not withdrawing the forepaws when these were stretched out horizontally in front of them, or if one Thalamus only was destroyed, in retaining the opposite leg in this position. No mechanical irritation of the Thalami produces either signs of pain or muscular movement; and this fact might at first appear to negative the doctrine that these organs are the ganglia of common sensation.§ But it must be borne in mind that the production of pain by mechanical injuries is by no means a universal phenomenon in the case of the nerve-*trunks* which minister to sensation—the olfactory, optic, and auditory nerves being exempted; and it need occasion still less surprise, therefore, that a nervous *centre* should be destitute of this kind of impressibility, which we have seen to be wanting also in the Spinal cord.

482. The effects of lesions of the Corpora striata are less distinctly marked. These bodies contain two masses of grey matter, a *nucleus caudatus* or intra-ventricular nucleus, and a *nucleus lenticularis*, or extra-ventricular nucleus.‖ (See Fig. 244). It is supposed by some, but it is purely hypothetical, that the corpora striata are the automatic centres of locomotion. The spring of their action lies in the functional activity of the cerebral hemispheres—that is, in the will; but when once started they may continue to act automatically, the exertion of the will being no longer required for the continuance of their movements, though it is, of course, always ready to hasten, arrest, or modify them. Nothnagel¶ found that puncture of a certain point of the nucleus caudatus of the corpus striatum, or its destruction by the injection of a minute portion of strong chromic acid caused rabbits, after a short interval, to leap and run forwards till they fell from exhaustion, and he applied the name 'nodus cursorius' to this spot. Destruction of the adjoining parts of the nucleus caudatus by the same means caused peculiar disturbance of the

‡ Nothnagel, "Virchow's Archiv," Band lxii. p. 203.

§ Nothnagel ("Centralblatt," 1874, p. 577) states that from numerous experiments on Rabbits he has satisfied himself—1. That the optic thalami have nothing to do with the innervation of voluntary movements. 2. That after their extirpation, no disturbance of cutaneous sensibility can be demonstrated. 3. That they appear to have a definite relation to the muscular sense.

‖ Ferrier ("West Riding Lunatic Asylum Rep.," vol. iii. p. 95) found that electrical stimulation applied to one corpus striatum caused pleurosthotonos, the flexors preponderating over the extensors, but this has not been corroborated by Glikz (Eckhard's "Beiträge," Band vii. p. 177) whose investigations were superintended by Eckhard.

¶ Virchow's "Archiv," Band lvii. pp. 184, 209.

movements of the legs.* Carville and Duret observed temporary paralysis of the muscles of the opposite side after extirpation of one nucleus caudatus. Mechanical stimulation of the *Lenticular nucleus*, acording to Nothnagel, causes deviation of the legs outwards and pleurosthotonos. In lesions limited to the caudate and lenticular nuclei the muscles of the opposite side are paralyzed, probably by compression of the fibres forming the internal capsule; but this paralysis is only temporary, and when the blood is absorbed, recovery takes place. When the lesion affects the posterior part of the lenticular nucleus, the sensory fibres of the internal capsule may undergo compression, and then, in addition to the motor paralysis, there is hemi-anæsthesia of the opposite side. It was affirmed by Magendie† that there exists in them a motor power which excites *backward* movement, and that a corresponding power of exciting *forward* movement exists in the Cerebellum; that these two powers ordinarily balance one another; but that, if either organ be removed, the power of the other will occasion a continual automatic movement, the removal of the Corpora striata causing an irresistible tendency to forward progression, whilst the division of the peduncles of the Cerebellum (according to him) occasions the reverse movement. These assertions, however, have not been confirmed by other experimenters. The results of removal of the Corpora striata with the anterior part of the Cerebral hemispheres are for the most part negative;‡ for the animal usually remains in a state of profound stupor, although still retaining the erect position; and it is only when irritated by pinching or pricking that it will execute any rapid movements. Burdon-Sanderson§ has shown that by direct irritation of the Corpus striatum, movements of the muscles of the opposite side can be produced, and that there is a certain correspondence in the groups of muscles that can thus be called into play, and those that are excited by irritation of definite regions of the intact cerebral hemispheres: on irritating the deepest part of the Corpus striatum, the animal opened its mouth, and alternately thrust out and retracted the tongue.‖

483. The fibrous tracts which connect these ganglionic masses with the Medulla oblongata are designated the *Crura cerebri*. These contain four sets of fibres, of which some connect the Spinal cord with the Encephalic centres; others, springing from the grey substance of the Medulla oblongata and Pons, run towards the hemispheres; a third set arise from the grey matter of the cerebral peduncles and run forwards to the cerebrum and backwards to the cerebellum; and others again extend from the corpora quadrigemina to the cerebrum. These several fasciculi are arranged so as to form an anterior layer named the *basis*, or *crusta*, of the cerebral peduncle, which is chiefly composed of motor fibres, though the outermost strand, sometimes called the fasciculus of Meynert, is sensory; and a superior or posterior layer, named the *tegmentum*, which is composed of sensory or afferent fibres. Between the two layers are darkly pigmented ganglion cells, constituting the *locus niger*. The sensory fibres of the tegmentum enclose the *red nucleus*, which is connected both with the cerebellum and the corpora quadrigemina. If the Crura cerebri are completely divided, the result, as might be anticipated, is the

* Carville and Duret "Sur les fonctions des Hêmisphéres Cérébraux," and Eckhard and Schwann, ("Hermann's Handbuch der Physiologie," 1878, Band ii. Th. 2. 132,) throw doubt on the existence of this *nodus cursorius*.

§ "Centralblatt," 1874, p. 513.

‖ Hitzig ("Centralblatt," 1874, p. 548) criticises Dr. Sanderson's statements.

annihilation of sensibility and of the power of voluntary movement in the body generally.* When, however, the Crura cerebri of a rabbit are not completely divided, but one of them is partially cut through a little in front of the Pons Varolii, the animal is said by Longet and Schiff to exhibit a constant tendency to turn towards the side opposite to that of the lesion, so that it performs the circular *évolution du manége ;* the diameter of its circle of movement being smaller in proportion as the incision approaches the edge of the Pons. But if one of the Crura be completely divided, the animal then falls over on the opposite side ; the limbs of that side being paralysed to the influence of the Encephalic centres, though they may be still caused to exhibit reflex motions. Hence it appears that the circular movements which are performed after incomplete lesions of the Crus cerebri and Thalamus opticus of either side, are due to the weakening of the sensori-motor apparatus of the opposite side, whereby the balance of the muscular actions of the two sides is destroyed. Nearly the same results have been obtained on this point by Longet, Lafargue, and Schiff. Afanasieff† found that in the course of two or three weeks an animal, in which one of the cerebral peduncles had been divided, was able to run straight forward. The section causes complete paralysis of the oculo-motorius on the same side, and imperfect paralysis of the facial nerve on the opposite side. Besides diminished sensibility of the body and head, it also produces contraction of the arteries, which lasts for 10 or 15 days, and is more marked in the ear of the *same* side. At the moment of section the blood pressure is increased, and the pulse retarded, and in half an hour the temperature of the body falls 3° F. Division of both peduncles destroys the power of voluntarily relaxing or constricting the sphincter ani, as well as of relaxing the constrictor urethræ.

484. Considerable importance is attached by some Physiologists to the part of the Encephalon known as the *Tuber annulare*, to which the name of *Mesocephaln* has also been given. This is not altogether synonymous with the *Pons Varolii*, as some Anatomists have represented it; for while the latter consists of transverse fibres which form the commissure between the hemispheres of the Cerebellum, surrounding and passing between the longitudinal fibres of the Sensory and Motor tracts which constitute the Crura cerebri, the Tuber annulare (which exists in animals whose Cerebellum has no hemispheres) is a projection from the surface of the proper Medulla oblongata, containing a considerable nucleus of vesicular matter. M. Brown-Séquard‡ has drawn the following conclusions respecting the functions of this part of the Encephalon, chiefly based on pathological evidence :—1. That the restiform bodies and their prolongations into the Pons, and into the Cerebellum, are not, as has been supposed, the conductors of sensory impressions. 2. That whilst hyperæsthesia occurs on the same side of the body when the Spinal cord is injured, especially in its posterior part, it appears on the opposite side of the body when a section is made either of the anterior or posterior surface of the Pons; and this he believes to favour his view of the decussation of the sensory fibres in the Cord, and to be opposed to the old view of the decussation of these

* It is considered by Longet that these functions are not *completely* destroyed, because the animals on whom this operation has been performed still retain some power of movement, and respond by cries to impressions that ordinarily produce pain. There is no proof, however, that such actions are other than 'excito-motor;' they certainly cannot in themselves be admitted as proving the persistence of consciousness in the lower segment of the Cerebro-Spinal axis. (See Brown-Séquard, "Central Nervous System," 1860, p. 225; and Schroeder v. d. Kolk, Syd. Soc. Trans., 1859, p. 76.)

† "Wien. Med. Wochensch.," pp. 137, 153, 169, and 185.

‡ "Journ. de la Physiol.," vol. i. p. 762; vol. ii. p. 121.

fibres below the Tubercula quadrigemina, or in the substance of the Pons itself. 3. The transmission of sensory impressions in the Pons appears to be chiefly effected by its central portion, whilst the anterior portion is chiefly instrumental in the conduction of the mandates of the Will to the Muscles. The experiments of Longet led him to the conclusion that the Tuber annulare, the structure of which is very complicated, is an independent centre of sensation and of motor power. He states that convulsive movements are excited by irritating it, and especially by the transmission of an electric current through its substance. These movements, according to Dr. Todd, appear to be of a different character from those which are excited by the application of the same stimulus to the Spinal cord and Medulla oblongata; for he states that while the convulsions excited by the transmission of an interrupted current through the parts just named, are *tetanic*, the muscles being thrown into a state of *fixed* contraction—those which ensue when the current is transmitted through the region of the Mesocephalon and Corpora quadrigemina, are *epileptic*, being combined movements of *alternate* contraction and relaxation, flexion and extension, affecting the muscles of all the limbs, of the trunk, and of the eyes, which roll about as in epilepsy.* Others† regard it as a centre for the automatic movements and muscular action required for locomotion and for standing, as well as for the perception of sensations of taste and of hearing.

485. The evidence afforded by Pathology regarding the functions of these Ganglionic masses is not altogether self-consistent; but this arises, probably, from the circumstance that the effects of morbid changes (particularly of sanguineous effusions) in any part of the Encephalon, extend themselves to other parts than those in which the obvious lesions are found; as is abundantly proved by the great variety of phenomena which present themselves as the results of lesions apparently similar, and by the similarity of the phenomena that are frequently consequent upon lesions of very different parts. It is established by abundant evidence that disease of the Corpora striata, or Thalami optici, or hæmorrhage into these bodies, produces hemiplegia, or paralysis of the opposite side. This paralysis, however, is not uniform, but affects chiefly the arm and leg, and in a less degree the face, whilst sensation is usually only slightly affected, or escapes altogether. An ingenious attempt has been made by Dr. Broadbent‡ to explain the phenomena observed in these cases. He observes that the relative situation of the two ganglia (Corpus striatum and Optic thalamus) will in some measure account for the circumstance that sensation so frequently escapes when motor power is lost; since the Corpus striatum—the motor ganglion—is in front of and external to the Thalamus, and may therefore easily be extensively damaged without involving the latter, or the fibres passing from it to the Cord. The Thalamus—the sensory ganglion—on the other hand, lying behind the Corpus striatum, and upon the fibres connecting it with the Cord, can scarcely be seriously affected without injury to those fibres or the Corpus striatum itself. Again, the Optic thalamus, according to hypothesis, standing with respect to the Corpus striatum in the relation of a sensory to a motor nerve-nucleus, it would almost follow that severe injury to the former would paralyze the latter by inhibitory influence, even when the injury was confined to the Thalamus, and did not reach the Corpus striatum directly or indirectly. Lastly, the experiments of M. Brown-Séquard may be referred to, as showing that, in the case of the Spinal cord, a very much more completed estruction of the grey matter is requisite

* Lumleian Lectures, 'On the Pathology and Treatment of Convulsive Diseases,' in "Medical Gazette," May 11, 1849. † Fort, "Physiologie Humaine," 1880, p. 63.
‡ "Med.-Chir. Rev.," April, 1866.

to destroy sensation entirely than is requisite for the abolition of the power of motion. Dr. Broadbent considers that the partial character of the paralysis may further be referred to the mode of functional activity of the muscles affected as compared with those which escape, and believes it may be shown that where the muscles of the corresponding parts on opposite sides of the body constantly act in concert, and seldom if ever independently, the nerve nuclei of these muscles are so connected by commissural fibres as to be *pro tanto* a single nucleus. This combined nucleus will have a set of fibres from each Corpus striatum, and will usually be called into action by both; but it will also be capable of being excited by either singly, though more or less completely according as the commissural connection between the two halves is more or less perfect. In support of this statement, it may be observed that those muscles which are commonly associated in their movements like the ocular muscles, are not paralyzed; those of the cheek, on the other hand, exhibit a degree of independence of action, and are slightly paralyzed; and lastly, the muscles of the arm and leg, which are almost completely independent in their action, are most severely affected. It is found also that in unilateral convulsion or spasm, the movements are bilateral in those parts which escape paralysis in Hemiplegia—*i.e.*, the combined nucleus transmits the irregular one-sided impulse along the nerves of both sides.

486. In employing the information derived from the foregoing sources as a guide in the inquiry into the part performed by the Sensory ganglia in the ordinary operations of the Cerebro-spinal system, we have to distinguish, as in the case of the Spinal Cord, between their operation as independent centres, and their action in subservience to the Cerebrum, which is superposed upon them.—We have seen reason to conclude that, in their former capacity, they are to be regarded as the true seat of *Sensation* (*i.e.* the material instruments through which the consciousness becomes affected by external impressions), and as the instrument, in virtue of their own 'reflex' power, of that class of Instinctive or Automatic movements, which require to be prompted and guided by sensations, and which cannot, therefore, be referred to the excito-motor group. But although it is sufficiently obvious that such movements constitute the highest manifestations of Animal life in the Invertebrata generally, and that they are but little modified by any higher principle of action even in the lower Vertebrata, yet it is no less obvious that in adult Man, in whom the Intelligence and Will are fully developed, we have comparatively little evidence of this independent reflex action of the Sensory ganglia:—all those automatic actions which are *immediately* necessary for the maintenance of his Organic life, being provided for by the excito-motor portion of the apparatus, so that although sensation ordinarily accompanies most of them, it is not essential to them; whilst those which are necessary to provide more *remotely* for its requirements, are for the most part committed to the guidance of his Reason. For the impressions which have been brought by the afferent nerves to his Sensorium, and which have there produced sensations, do not in general react at once upon the motor apparatus (as they do in those animals in which the Sensory ganglia are the *highest* of the nervous centres), but usually transmit their influence upwards to the Cerebrum, through whose instrumentality they give rise to ideas and reasoning processes, which operate upon the motor apparatus either emotionally or volitionally. And it is for the most part only when this upward transmission is checked, either by the non-development or the functional inactivity of the Cerebrum, or by its complete occupation in some other train of action—or, on the other hand, when the reflex action of the Sensory ganglia is called into play with unusual potency—

that we have any manifestations of the *sensori-motor* or *consensual* mode of operation in Man, that are at all comparable in variety or importance to those instinctive acts which are so remarkable in the lower animals.

487. Still, sufficient evidence of the existence of this class of reflex movements may be drawn from observation of the actions of Man in his ordinary condition; examples of it being furnished (as we have seen) by the closure of the eyes to a dazzling light, the start caused by a loud and unexpected sound, and the sneezing excited by sensory impressions on the Schneiderian membrane or on the Retina. To these may be added the vomiting produced by various sensory impressions, as the sight of a loathsome object, a disagreeable smell, a nauseous taste, or that peculiar feeling of want of support which gives rise to 'sea-sickness,' especially when combined with the sight of continually-shifting lines and surfaces, which itself in many individuals disposes to the same state; the involuntary laughter which is excited by tickling, and also that which sometimes bursts forth at the provocation of some sight or sound to which no ludicrous idea or emotion can be attached; the yawning which is excited by an internal sensation of uneasiness (usually arising from deficient respiration), or by the sight or sound of the act as performed by another; and those involuntary movements of the body and limbs, excited by uneasy sensations (probably muscular), which are commonly designated as 'the fidgets.' When the reflex activity of the Sensory ganglia is more strongly excited, in consequence either of an unusual potency of the sensory impressions, or of an unusual excitability of this part of the nervous centres, a much greater variety of sensori-motor actions is witnessed. The powerful involuntary contraction of the orbicularis and of the muscles which roll the eyeball upwards and inwards, in cases of excessive irritability of the retina is one of the best examples of this kind; but another very curious illustration is afforded by the involuntary abridgment of the excito-motor actions of respiration, when the performance of these is attended with pain—the dependence of this abridgment upon the direct stimulus of sensation, rather than upon voluntary restraint, being obvious from the fact that it often presents itself on *one* side only, a limitation which the Will cannot imitate. Again, there are certain Convulsive disorders which appear to depend upon an undue excitability of these centres, the paroxysms being excited by impressions which act through the organs of sense, and are not thus operative unless the patient be conscious of them; thus in Hydrophobia, we observe the immediate influence of the sight, sound, or contact, of liquids, or of the slightest currents of air, in exciting muscular contractions: and in many Hysteric subjects, the sight of a paroxysm in another individual is the most certain means of its induction in themselves. A remarkable case of this general exaltation of purely sensorial excitability has been recorded by Dr. Cowan, who gives the following account of its phenomena, which can scarcely be referred to any other than this category. "The shadow of a bird crossing the window, though the blind and bed-curtains are closed, the displacement of the smallest portion of the wick of a candle, the slightest change in the firelight, induce a sudden jerking of the spinal muscles, extending to the arms and legs when violent, and this without the slightest mental emotion of any kind beyond a consciousness of the movement. At times the vocal organs are implicated, and a slight cry, quite involuntary, takes place. At these periods the patient is unusually susceptible of all noises, especially the least expected and least familiar. Movements in the next house inaudible to others, the slightest rattle in the lock of a door, tearing a morsel

of paper, and a thousand little sources of sound not to be catalogued, induce results similar to those of visual impressions."*

488. It is, however, when the Cerebrum is not in a state which renders it capable of receiving and acting-upon Sensorial impressions, that we find the independent reflex activity of the Sensory ganglia most strikingly displayed. Thus, in the Infant for some time after its birth, it is obvious to an attentive observer, that a large part of its movements are directly prompted by sensations to which it can as yet attach no distinct ideas, and that they do not proceed from that *purposive* impulse which is essential to render them voluntary. This is well seen in the efforts which it makes to find the nipple with its lips; being probably guided thereto at first by the smell, but afterwards by the sight also; when the nipple has been found, the act of suction is purely excito-motor, as already explained. So in the Idiot whose brain has never attained its normal development, the influence of sensations in directly producing respondent movements is obvious to all who examine his actions with discrimination; and a remarkable case has been described,† in which an entire though temporary suspension of Cerebral power, reducing the subject of it to the condition of one of the lowest Vertebrata, gave a very satisfactory proof of the independent action of this division of the Encephalic centres.

489. But we do not require to go so far in search of characteristic examples of this kind of reflex action; since they are afforded by the performance of *habitual* movements, which are clearly under Sensorial guidance, when the Cerebrum is occupied in some train of action altogether disconnected with them. An individual who is subject to 'absence of mind,' may fall into a reverie whilst walking the streets; his attention may be entirely absorbed in a train of thought, and he may be utterly unconscious of any interruption in its continuity; and yet during the whole of that time his limbs shall have been in motion, carrying him along the accustomed path, whilst his vision shall have given to those movements the direction which is requisite to guide him along a particular line, or to move him out of it for the avoidance of obstacles. As already pointed-out there seems strong reason for regarding the ambulatory movements of the limbs as in themselves excito-motor; but the *guidance* of these movements by the visual sense indicates the participation of the Sensorium in this remarkable performance.—It has been maintained by some Metaphysicians and Physiologists, that these 'secondarily automatic' actions always continue to be voluntary, because their performance is originally due to a succession of volitional acts, and because, in any particular case, it is the Will which first excites them, whilst an exertion of the Will serves to check them at any time. But this doctrine involves the notion that the Will is in a state of pendulum-like oscillation between the train of thought and the train of movement; whereas nothing is more certain to the individual who is the subject of both, than that the former may be as uninterrupted as if the body were perfectly at rest, and his reverie were taking place in the quietude of his own study. And as it commonly happens that the direction taken is that in which the individual is most in the habit of walking, it will not unfrequently occur that if he had previously intended to pursue some other, he finds himself, when his reverie is at an end, in a locality which may be very remote from that towards which his walk was originally destined; which would not be the case, if his movements had been still under the purposive direction of the Will. And although it is perfectly true that these movements can be at any time checked by an effort of the will, yet this

* "Lancet," Oct. 4, 1845. † Ibid, Nov. 15 and 29, 1845.

does not really indicate that the will has been previously engaged in sustaining them; since, for the will to act upon them at all, the *attention* must be recalled to them, and the Cerebrum must be liberated from its previous self-occupation. And the gradual conversion of a volitional into an automatic train of movements, so that at last this train, once started, shall continue to run-down of itself, will be found to be less improbable than it would at first appear, when it comes to be understood that the mechanism of both sets of actions is essentially the same, and that they merely differ as regards the nature of the stimulus which originally excites them. That the same automatic movements are not excited by the same sensations, when the Cerebrum is in its ordinary state of functional connection with the Sensorium, is a fact entirely in harmony with the principle already laid-down. The complete occupation of the mind in other ways, as in close conversation or argument, or even (it may be) in the voluntary direction of some other train of muscular movements, is no less favourable than the state of reverie to that independent action of the Automatic centres which has been now described.

490. In the state of entire functional activity of the nervous centres of Man, however, there can be no doubt that the operation of the Sensory Ganglia is entirely subordinated to that of the Cerebrum; and that it furnishes an essential means of connection between the actions of the Cerebrum on the one hand, and those of the organs of Sense and Motion on the other, by the combination of which the Mind is brought into relation with the external world. For, in the first place, it may be affirmed with certainty that no mental action can be originally excited, save by the stimulus of Sensations; and it is the office of the Sensory ganglia to form these out of the impressions brought to them from the organs of sense, and to transmit such sensorial changes to the Cerebrum. But they have a no less important participation in the downward action of the Cerebrum upon the Motor apparatus; for no voluntary action can be performed without the assistance of a *guiding sensation*, as was first prominently stated by Sir C. Bell.*—In the majority of cases, the guiding or controlling sensation is derived from the muscles themselves, of whose condition we are rendered cognizant by the sensory nerves with which they are furnished; but there are certain cases in which it is ordinarily derived from one of the special senses, and in which the 'muscular sense' can only imperfectly supply the deficiency of such guidance; whilst, again, if the 'muscular sense' be deficient, one of the special senses may supply the requisite information. The proof of this necessity is furnished by the *entire impossibility of making or sustaining voluntary efforts, without a guiding sensation of some kind.* Thus, in complete anæsthesia of the lower extremities, without loss of muscular power, the patient is as completely unable to walk as if the motor nerves had also been paralyzed, unless the deficient sensorial guidance be replaced by some other; and in similar affections of the upper extremities, there is a like inability to raise the limb or to sustain a weight. But in such cases, the deficiency of the 'muscular sense' may be made good by the visual; thus, the patient who cannot feel either the contact of his foot with the ground, or the muscular effort he is making, can manage to stand and walk by *looking* at his limbs; and the woman who cannot feel the pressure of her child upon her arms, can yet sustain it so long as she keeps her eyes fixed upon it, but no longer—the muscles ceasing to contract, and the limb drooping powerless, the moment that the eyes are withdrawn from it. Thus it is, too, that when we are about to make a muscular effort,

* See his chapter 'On the Nervous Circle which connects the Voluntary Muscles with the Brain,' in his work, "On the Nervous System of the Human Body."

the amount of force which we put forth is governed by the mental conception of that which will be required, as indicated by the experience of former sensations; just as the contractions of the muscles of vocalization are regulated by the conception of the sound to be produced. Hence, if the weight be unknown to us, and it prove either much heavier or much lighter than was expected, we find that we have put forth too little or too great a muscular effort.

491. There are two groups of muscular actions, however, which, although no less voluntary in their character than the foregoing, are yet habitually guided by other sensations than those derived from the muscles themselves. These are, the movements of the *Eyeball*, and those of the *Vocal apparatus*.—The former are directed by the visual sense,* by which the action of the muscles is guided and controlled, in the same manner as that of other muscles is directed by their own 'muscular sense;' and hence it happens that, when we close our eyes, we cannot move them in any required direction without an effort that strongly calls-forth the muscular sense by which the action is then guided. In persons who have become blind after having once enjoyed sight, an association is formed by habit between the muscular sense and the contractile action, that enables the former to serve as the guide after the loss of the visual sense; but in those who are born *perfectly* blind, or who have become so in early infancy, this association is never formed, and the eyes of such persons exhibit a continual indeterminate movement, and cannot by any amount of effort be steadily fixed in one spot, or be turned in any definite direction. A very small amount of the visual sense, however, such as serves merely to indicate the direction of light, is sufficient for the government of the movements of the eyeball.—In the production of vocal sounds, again, that nice adjustment of the muscles of the Larynx, which is requisite to the giving forth of determinate tones, is ordinarily directed by the auditory sense: being learned in the first instance under the guidance of the sounds actually produced; but being subsequently effected voluntarily, in accordance with the mental conception (a sort of inward sensation) of the tone to be uttered, which conception cannot be formed, unless the sense of hearing has previously brought similar tones to the mind. Hence it is that persons who are born *deaf* are also *dumb*. They may have no malformation of the organs of speech; but they are incapable of uttering distinct vocal sounds or musical tones, because they have not the guiding conception, or recalled sensation, of the nature of these. By long training, however, and by imitative efforts directed by muscular sensations in the larynx itself, some persons thus circumstanced have acquired the power of speech; but the want of a sufficiently definite control over the vocal muscles is always very evident in their use of the organ.—It is very rarely that a person who has once enjoyed the sense of hearing, afterwards becomes so *completely* deaf, as to lose all auditory control over his vocal organs. An example of this kind, however, has been communicated to the public by a well-known author, as having occurred in himself; and the record of his experiences† contains many points of much interest. The deafness was the result of an accident occurring in childhood, which left him for some time in a state of extreme debility; and when he made the attempt to speak, it was with considerable pain in the vocal organs. This pain probably resulted from the unaccustomed effort which it was necessary to make, when the usual guidance was wanting; being analogous to the uneasiness which we experience, when we attempt to move our eyes with the lids closed. His

* See Dr. Alison's Memoir on the 'Anatomical and Physiological Inferences from the Study of the Nerves of the Orbit,' in "Trans. of Roy. Soc. of Edinb.," vol. xv.

† See the "Lost Senses," by Dr. Kitto, vol. i. chapters ii. and iii.

voice at that time is described as being very similar to that of a person born deaf-and-dumb, but who has been taught to speak. With the uneasiness in the use of the vocal organs, was associated an extreme mental indisposition to their employment; and thus, for some years, the voice was very little exercised. Circumstances afterwards forced it, however, into constant employment; and great improvement subsequently took place in the power of vocalization, evidently by attention to the indications of the muscular sense. It is a curious circumstance fully confirming this view, that the words which had been in use previously to the supervention of the deafness, were still pronounced (such of them, at least, as were kept in employment) as they had been in childhood; the muscular movements concerned in their articulation having still been guided by the original auditory conception, in spite of the knowledge derived from the information of others that such pronunciation was erroneous. On the other hand, all the words subsequently learned were pronounced according to their spelling; the required associations between the muscular sensations and the written signs being in this case the obvious guide.

492. It is through the 'muscular sense,' in combination with the visual and tactile, that those movements are regulated which are concerned alike in ordinary progression, and in the maintenance of the equilibrium of the body. That the visual sense has, in most persons, a large share in this regulation, is evident from the simple fact, that no one who has not been accustomed to the deprivation of it, can continue to walk straight-forwards, when blind-folded, or in absolute darkness, towards any point in the direction of which he may have been first guided. But the blind man, who has been accustomed to rely exclusively upon his muscular sense, has no difficulty in keeping to a straight path; and moves onwards with a confidence which is in remarkable contrast with the gait of a man who has been deprived of sight for the occasion only. In fact, as Mr. Mayo has well remarked,* in our ordinary movements, "we lean upon our eyesight as upon crutches."—When our vision, however, instead of aiding and guiding us, brings to the mind sensations of an antagonistic character, our movements become uncertain, from the loss of that power of guidance and control over them, which the harmony of the two sensations usually gives. Thus, a person unaccustomed to look down heights, *feels* insecure at the top of a tower or a precipice, although he *knows* that his body is properly supported; for the void which he sees below him contradicts (so to speak) the tactile sensations by which he is made conscious of the due equilibrium of his body. So, again, although any one can walk along a narrow plank, which forms part of the floor of a room, or which is elevated but a little above it, without the least difficulty, and even without any consciousness of effort, if that plank be laid across a chasm, the bottom of which is so far removed from the eye that the visual sense gives no assistance, even those who have braced their nerves against all emotional distraction, feel that an effort is requisite to maintain the equilibrium during their passage over it; that effort being aided by the withdrawal of the eyes from the abyss below, and the fixation of them upon a point beyond, which at the same time helps to give steadiness to the movements and distracts the mind from the sense of its danger. The degree in which the 'muscular sense' is alone sufficient for the guidance of such movements, when the mind has no consciousness of the danger, and when the visual sense neither affords aid nor contributes to distract the attention, is remarkably illustrated by the phenomena of Somnambulism; for the sleep-walker traverses, without the least hesitation, the narrow parapet of a house, and crosses narrow and insecure

* "Outlines of Physiology," 3rd edit., p. 345.

planks, clambers roofs, &c., under circumstances that clearly indicate the nature of the guidance by which he is directed.—The dependence of our ordinary power of maintaining our equilibrium, upon the combination of the guiding sensations derived through the sight and the touch, is further well illustrated, as Mr. Mayo has pointed out (loc. cit.), by what happens to a landsman on first going to sea. "It is long before the passenger acquires his 'sea legs.' At first, as the ship moves, he can hardly keep his feet; the shifting lines of the vessel and surface of the water unsettle his visual stability; the different inclinations of the planks he stands-on, his muscular sense. In a short time he learns to disregard the shifting images and changing motions, or acquires facility in adapting himself (like one on horseback) to the different alterations in the line of direction in his frame." And when a person who has thus learned by habit to maintain his equilibrium on a shifting surface, first treads upon firm ground, he feels himself almost as much at fault as he did when he first went to sea; and it is only after being some time on shore, that he is able to resume his original manner of walking. Indeed, most of those who spend the greater part of their time at sea, acquire a peculiar gait, which becomes so habitual to them that they are never able to throw it off.

493. But further, there is very strong physiological evidence that the Sensory ganglia are not merely the instruments whereby our voluntary movements are directed and controlled, in virtue of the guiding sensation which they furnish, but that they are actually the immediate centres of the motor influence which excites muscular contractions, in obedience to impulses transmitted downwards from the Cerebrum. It has usually been considered that the Cerebrum acts directly upon the muscles, in virtue of a direct continuity of nerve fibres from the grey matter of its convolutions, *through* the Corpora striata, the motor tract of the Medulla oblongata, the anterior portion of the Spinal cord, and the anterior roots of the nerves; and that in the performance of any voluntary movement, the Will determines the motor force to the muscle or set of muscles by whose instrumentality it may be produced. To this doctrine, however, the anatomical facts already stated constitute a very serious objection; for the motor tract cannot be stated with certainty to have any higher origin than the Corpora striata; and it is impossible to imagine that the fibres which converge towards the surface of these bodies from all parts of the Cerebrum, can be so closely compacted together as to be included in the motor columns of the Spinal axis. The fact would rather seem to be, that these converging fibres bear the same kind of anatomical relation to the Corpora striata and the other Sensorial centres of motor power, as do the fibres of the afferent nerves which proceed to them from the retina, the Schneiderian membrane, and the other peripheral expansions of nervous matter; and hence we might infer that the nerve-force generated in the convolutions, instead of acting *immediately* on the motor nerves, is first directed towards the Automatic centres, and excites the same kind of motor response in them, as would be given to an impression transmitted to them through a sensory nerve. We shall find that such a view of the structural arrangements of these parts is in remarkable accordance with their functional relations, as indicated by a careful analysis of the mechanism of what is commonly regarded as 'voluntary' movement. The Cerebrum may thus call the motor apparatus into action, as the instrument either of *ideas*, of *emotions*, or of *volitional determinations;* but we must limit our present examination to *voluntary* movements alone, these having been usually regarded as in such complete antagonism to those of the automatic group, that even separate sets of nerve-fibres have been thought requisite to account

for the transmission of these two distinct orders of motor impulses to the muscles.

494. Now, in the first place, it may be asserted, with some confidence, that no effort of the Will *can* exert that direct influence on the muscles which our ordinary phraseology, and even the language of scientific reasoners, would seem to imply; but, on the other hand, that the Will is solely concerned in determining the *result;* the selection and combination of muscular movements required to bring about this result, *not* being effected by the Will, but by some intermediate agency. If it were otherwise, we should be dependent upon anatomical knowledge for our power of performing the simplest movement of the body; whereas we find the fact to be, that the man who has not the least idea of the mechanism of muscular action, can acquire as complete a command over his movements, and can adapt them as perfectly to the desired end, as the most accomplished anatomist could do. Further, we cannot, by any exertion of the Will, single out a particular muscle, and throw it into contraction by itself, unless that muscle be one which is alone concerned in an action that we can voluntarily perform; and even then we single it out by *willing* the action. Thus we can put the *levator palpebræ* in action by itself; but this we do, not by any conscious determination of power to the muscle itself, but by *willing* to raise the eyelids; and it is only by our anatomical knowledge that we know that but a single muscle is concerned in this movement. So far as our own consciousness can inform us, there is no difference between the mechanism of this action and that of the flexion of the knee- or elbow-joint; and yet in these latter movements several muscles are concerned, not one of which can be singled-out by any effort of the will, and thrown into action separately from the rest.—The idea that the Will is *directly* exerted upon the muscles called into action to produce a particular movement, may seem to derive some support from the sense of *muscular effort* of which we are conscious in making the exertion, and which we refer to the muscles which are concerned in it; but this sense of effort is nothing else than the 'muscular sense' already alluded to, which has its origin in the state of tension of the muscles, and which is no more an indication of *mental* effort directed to them, than the sensation of light or sound is an indication of a determination of voluntary power to the eyes or ears.

495. There are two cases, already referred to under another head, in which it is very easy to show that the Will is concerned with the result alone, and is not directly exerted upon the instruments by which that result is brought about: these are, the movements of the eyes, and the production of vocal tones. In neither of them are we conscious of any effort in the muscular apparatus, unless the contraction be carried beyond its accustomed extent; the ordinary movements being governed, as already remarked, not by the muscular sense, but by the visual and auditory senses respectively.—Nothing can be more simple, to all appearance, than the act of turning the eyes upwards or downwards, to one side or the other, in obedience to a determination of the Will; and yet the Will does not impress such a determination upon the muscles. That which the Will really does, is to cause the eyeballs to roll in a given direction, in accordance with a visual sensation; and it is only *when there is an object* towards which the eyes can be turned that we can move them with our usual facility. When the eyelids are closed, and we attempt to roll the globes upwards or downwards, to one side or to the other, we feel that we can do so but very imperfectly, and with a sense of effort referred to the muscles themselves—this sense being the result of the state of tension in which the muscles are placed by the effort to move the eyes without the guiding visual

sensation. Now, on the other hand, the Will may determine to fix the eyes upon an object; and yet this very fixation may be only attainable by a muscular movement, which movement is directly excited by the visual sense, without any exertion of voluntary power over the muscles. Such is the case when we determinedly look steadily at an object, while we move the head horizontally from side to side; for the eyeballs will then be moved in the contrary direction by a kind of instinctive effort of the external and internal recti, which tends to keep the retinæ in their first position, and to prevent the motion of the images over them. So, when we look steadily at an object, and incline the head towards either shoulder, the eyeballs are rotated upon their antero-posterior axis (probably by the agency of the oblique muscles) apparently with the very same purpose—that of preventing the images from moving over the retinæ (see CHAP. XV., sect. 3). Now we cannot refuse to this rotation any of the attributes which really characterize the so-called voluntary movements; and yet we are not even informed by our own consciousness that such a movement is taking place, but know it only by observation of others, or by the reflection in a mirror.

496. The muscular contractions which are concerned in the production of vocal tones, are, in like manner, always accounted voluntary; and yet it is easy to show that the Will has no direct power over the muscles of the larynx. For we cannot raise or depress the larynx as a whole, nor move the thyroid cartilage upon the cricoid, nor separate or approximate the arytenoid cartilages, nor extend or relax the vocal ligaments, by simply *willing* to do so, however strongly. Yet we can readily do any or all these things by an act of the Will exerted for a specific purpose. We conceive of a tone *to be* produced, and we *will* to produce it; a certain combination of the muscular actions of the larynx then takes place, in most exact accordance with one another; and the predetermined tone is the result. This anticipated or conceived sensation is the guide to the muscular movements, when as yet the utterance of the voice has not taken place; but whilst we are in the act of speaking or singing, the contractile actions are regulated by the present sensations derived from the sounds as they are produced.—It can scarcely but be admitted, then, that the Will does *not* directly govern the movements of the larynx; but that these movements are immediately dependent upon some other agency.

497. Now what is true of the two preceding classes of actions is equally true of all the rest of the so-called *voluntary* movements; for in each of them the power of the Will is really limited to the determination of the result; and the production of that result is entirely dependent upon the concurrence of a 'guiding sensation,' which is usually furnished by the very muscles that are called into action. It is obvious, therefore, that we have to seek for some intermediate agency, which *executes* the actions *determined* by the Will; and when the facts and probabilities already stated are duly considered, they tend strongly in favour of the idea that even voluntary movements are executed by the instrumentality of the automatic apparatus, and that they differ only from the automatic or instinctive in the nature of the stimulus by which they are excited—the determination of the Will here replacing, as the *exciting cause* of its action, the sensory impression which operates as such in the case of an instinctive movement, and which is still requisite for its guidance.

498. This view of the case derives a remarkable confirmation from the analysis of two classes of very familiar phenomena: the first consisting of cases in which movements that are ordinarily Automatic are performed by Voluntary determination, or simply in respondence to an Idea; the second consisting of those in which movements originally Voluntary come by habit

to be Automatically performed.—Of the first class, the act of Coughing is a good example. This action, which is ordinarily automatic, may also be excited by a voluntary determination; such a determination, however, is directed to the *result*, rather than exercised in singling-out the different movements and then combining them in the necessary sequence; and the Will thus seems obviously to take the place of the laryngeal or tracheal irritation, as the *primum mobile* of the series, which, in its actual performance, is as automatic in the latter case as in the former. So, again, we know that many of the automatic movements which have been already referred-to as examples of the sensori-motor group (§ 487), and which the Will cannot call-forth, may be performed in respondence to *ideas* or *conceptions*, which are Cerebral states that seem to recall the same condition of the Sensorium as that which was originally excited by the Sensory impression. Thus it is well known that the act of Vomiting may be induced by the *remembrance* of some loathsome object or nauseous taste, excited by some act of 'suggestion;' and the Author has known an instance in which a violent fit of sea-sickness was brought-on by the sight of a vessel tossed about at sea, which recalled the former experience of that state. So the Hydrophobic paroxysm may be excited by the mention of the *name* of water, which of course calls up the idea; and a tendency to yawn is in like manner frequently induced by looking at a picture of yawners, or by speaking of the act, or by voluntarily commencing the act which may then be automatically completed. The automatic performance of actions which were originally voluntary has already been fully discussed (§489); and we have therefore only to remark here, that the fact very strongly supports the view now advanced, as to the *singleness* of the mechanism which serves as the instrument of both classes of actions, and the essential uniformity of its operation in the two cases.—It would be difficult to explain either set of phenomena satisfactorily, on the hypothesis that there is a 'distinct system' of fibres for the volitional and for the automatic movements; since it is not readily to be conceived how a set of movements originally performed by the one can ever be transferred to the other; whilst, on the other hand, it is easy to understand how the same motorial action may be excited in the automatic centres, either by an *external* impression conveyed thither by an afferent nerve from a sensory surface (as that of the irritation in the air-passages, which excites the act of coughing), or by a stimulus proceeding from the convoluted surface of the Cerebellum, and conveyed along those connecting fibres which Reil with great sagacity termed the 'nerves of the *internal* senses.'

499. To sum-up, then, we seem justified in concluding that the *Cranio-spinal axis* of Man and other Vertebrata—consisting of the Sensory ganglia, Medulla oblongata, and Spinal cord—is (like the chain of cephalic and ventral ganglia of Arthropoda with which it is homologous) the immediate instrument of *all sensorial and motor changes:* that by its sole and independent action are produced all those movements which are ranked as *automatic* or *instinctive*, these being performed in respondence to external impressions which may or may not affect the consciousness; but that when acting in subordination to the Cerebrum, the Cranio-spinal axis transmits upwards to it the influence of Sensorial changes, and receives from it the downward impulses, which it directs automatically into the appropriate channel for the execution of the movements which the mind has directed. The number of purely-automatic actions diminishes in proportion to the development of the Cerebrum, and to the subjection of the Automatic apparatus to its control; but even in Man, those most closely connected with the maintenance of the organic functions, or most necessary for the conservation of the bodily structure, remain

quite independent of any mental agency, and most of them do not require consciousness for their excitation. But if the activity of the Cerebrum be suspended or be otherwise directed, without any affection of the automatic apparatus, movements which have long been habitually performed in a particular sequence, may be kept-up, when the will has once set them in action, through the automatic mechanism alone; the impressional or sensational change produced by each action, supplying the stimulus which calls forth the next.—It may further be concluded that the Sensory ganglia, which are the instruments whereby we are rendered *conscious* of external impressions, are also the seat of those simple *feelings* of pleasure and pain which are immediately linked-on to that consciousness; for it can scarcely be doubted that such feelings must be associated with particular sensations, in animals that have no ganglionic centres above these; since we must otherwise regard the whole series of the Invertebrata as neither susceptible of enjoyment, nor capable of feeling pain or discomfort. And it likewise seems probable that the Sensory ganglia are also the seat of those *perceptional* acts which bring the consciousness into direct relation with the external object that aroused the sensation; since the recognition of *externality* seems evident in the actions of the tribes just referred to.* A few remarks may here perhaps appropriately be introduced, indicating the effects of lesion of the several ganglia at the base of the brain from above downwards. In the event of lesion, as hæmorrhage, occurring in front of or above the Corpora striata, no paralysis either motor or sensory is observed unless the damage be very great. The intellectual faculties are probably always more or less affected, though it may not be easy to determine in what mode or to what degree. As will subsequently be shown, if the posterior frontal convolutions, especially of the left side, be affected, aphasia is likely to occur. If the hæmorrhage occur in the Corpus striatum, there is *motor* paralysis of the opposite side only. If in the Thalamus opticus there would be motor paralysis of the opposite side, with more or less paralysis of sensation. If in the Crus cerebri there would be paralysis of the opposite side, which might be either motor or sensory, or both; and if the muscles of the eye be paralysed, it is on the same side, and would chiefly affect those supplied by the third. If in the Pons, there would be paralysis of motion or of sensation, or of both, of the opposite side of the body and the same side of the face—in those muscles mainly supplied by the 5th and 7th, that is—there would be crossed paralysis. If in the Medulla oblongata, the great centres of respiration, deglutition, &c., would be affected, and a fatal issue soon occurs.

4. *Of the Cerebellum, and its Functions.*

500. The Cerebellum is an organ which, though confined to the Vertebrate Sub-Kingdom, is yet in peculiarly intimate relation with the Automatic apparatus. In that highest state of development which it presents in Man, we find it to consist of two *lateral* lobes or *hemispheres*, composed of nerve-fibres invested in a very peculiar manner by vesicular substance, and of a *central* lobe, also containing a combination of the vesicular and fibrous substances, which is known under the designation of the 'vermiform process.' The hemispheres are connected with each other not only by this central lobe, but also by the fibrous commissure which passes beneath the Medulla oblongata, and is known as the 'Pons Varolii.' The commissural fibres form part of the 'Crura cerebelli;' but another portion is formed by the strands which

* It may here be remarked that the term Sensation is now understood to imply the simple consciousness of an impression, whilst Perception refers that impression to something out of the *ego*. For the production of a Sensation a conscious state of the mind is all that is required; but for the exercise of the Perceptive power a certain degree of *attention* is requisite.

connect the Cerebellum with the anterior and posterior columns of the Spinal cord and Medulla oblongata; and, in addition to these, we find a fasciculus of fibres passing between the Cerebellum and the Corpora quadrigemina, the 'iter a cerebello ad testes.' The peduncle of its hemispheres on either side contains a mass of grey matter, the 'corpus rhomboideum,' or, 'dentatum,' which seems to be a ganglionic centre for the fibres that pass upwards to it from the Spinal cord. There are, then, three masses of grey matter in the cerebellum—that of the cortex, the dentated nuclei and the roof-nuclei of Stilling, situated in the medulla of the Vermiform process. The accompanying figure (Fig. 241) exhibits the appearance presented when a section of the cortex of the Cerebellum is examined, and it will be seen that it differs considerably from that of the Cerebrum given on p. 662.* The inquiries of Engel† have shown that the development of the Cerebellum is completed in infancy, and remains unaltered up to the 50th year, after which the number of the lamellæ, especially of the superior vermiform process, begins to diminish.

501. When we examine into the relative development of the Cerebellum in the different classes of Vertebrata, we find that it presents some very remarkable differences.‡ In its simpler forms, this organ is found to consist entirely of the representative of the *central* lobe of the Human Cerebellum, the hemispheres not making their appearance until we have ascended to the class of Birds. On ascending the scale of Mammiferous animals, on the other hand, we cannot but be struck with the rapid advance in the proportional size of the Cerebellum, which we observe as we rise from the lowest (which are surpassed in this respect by many Birds), towards Man, in whom it attains a development which appears enormous, even when contrasted with that of the Quadrumana. In proportion, in fact, as the extremities acquire the power of prehension, and together with this a power of application to a great variety of purposes—still more, in proportion as the animal becomes capable of maintaining the erect posture, in which a constant muscular exertion, consisting of a number of most elaborately-combined actions, is required—do we find the size of the Cerebellum, and the complexity of its structure, undergoing a rapid increase. Thus, even between the Dog and Bear there is a marked difference; the latter being capable of remaining for some time in the erect posture, and often spontaneously assuming it; whilst to the former it is anything but natural. In the semi-erect Apes, again, there is a very great advance in the proportional size of the Cerebellum; and those which most approach Man in the tendency to preserve habitually the erect posture also come nearest to him in the dimensions of this organ.—Thus on looking at the

‡ See "Princ. of Comp. Phys., § 635.—Fuller information on this point will be found in M. Serres' "Anat. Comp. du Cerveau," and M. Leuret's "Anat. Comp. du Système Nerveux." —For a general discussion of the evidence afforded by Comparative Anatomy in regard to the functions of the Cerebellum, see the "Brit. and For. Med. Rev.," vol. xxii. pp. 535–541.

size of the Cerebellum, in relation to the general motor activity of the Vertebrate classes respectively, and especially taking into account the *variety* of their respective movements, and the number of separate muscular actions which are combined in each, we can scarcely help noticing that it is in the tribes which are most distinguished in these respects, that the largest Cerebellum is usually found. Now it is evident that Man, although far inferior to many of the lower animals in the power of performing various particular kinds of movement, far surpasses them all in the number and variety of the combinations which he is capable of executing, and in the complexity of the combinations themselves. Thus, if we attentively consider the act of *walking*, we shall find that there is scarcely a muscle of the trunk or extremities which is not actively concerned in it; some being engaged in performing the necessary movements, and others in maintaining the equilibrium of the body which is disturbed by them. On the other hand, in the Horse or Camel, the muscular movements are individually numerous, but they do not require nearly the same perfect co-ordination. And in the Bird, the number of muscles employed in the movements of flight, and in directing the course of these, is really comparatively small; as may at once be perceived, by comparing the rigidity of the skeleton of the trunk of the Bird with that of Man, and by remembering the almost complete inactivity of the lower extremities during the active condition of the upper. In fact, the motions of the wings are so simple and regular, as to suggest the idea, that, as in Insects, their character is more reflex than voluntary:—an idea which is supported by the length of time during which they can be kept up without apparent fatigue, and also by the important facts which experimental research has disclosed.

502. We have next to inquire what evidence can be drawn from Experimental investigations on the same subject; and in reference to this it is desirable to remark, in the first place, that the experimental mode of inquiry is perhaps more applicable to this organ than to other parts of the Encephalon; inasmuch as it can be altogether removed with little disturbance of the actions immediately essential to life, the animals soon recovering from the shock of the operation, and seeming but little affected except in some easily recognized particulars.* It is not to be expected that there should be an exact conformity among the results obtained by all experimenters. Everyone who has been engaged in physiological experiments is aware of the amount of difference caused by very minute variations in their circumstances; in no department of inquiry is this more the case than in regard to the Nervous System; and such differences are yet more likely to occur in experiments made upon its centres than in those which concern its trunks.—The investigations of Flourens† seem the most clear and decisive in their results; and of these we shall accordingly take a general survey. He found that, when the Cerebellum was mechanically injured, the animals gave no signs of sensibility, nor were they affected with convulsions. When the Cerebellum was being removed by successive slices, the animals became restless, and their movements were irregular; and by the time the last portion of the organ was cut away, the animals had entirely lost the power of springing, flying, walking, standing, and preserving their equilibrium—in short, of performing any combined muscular movements, which are not of a simply reflex character. When an animal in this state was laid upon the back, it could not recover its former posture; but it fluttered its wings and did not lie in a state of stupor. When placed in the erect

* The principal experimenters upon this subject have been Rolando, Flourens, Magendie, Hertwig, Longet, Schiff, Brown-Séquard, Wagner, Hitzig, and Ferrier.

† "Récherches Expérim. sur les Propriétés et les Fonctions du Système Nerveux."

position, it staggered and fell like a drunken man—not, however, without making efforts to maintain its balance. When threatened with a blow, it evidently saw it, and endeavoured to avoid it. It did not seem that the animal had in any degree lost voluntary power over its several muscles; nor did sensation appear to be impaired. The faculty of *combining* the actions of the muscles in groups, however, was completely destroyed; except so far as those actions (like that of Respiration) were dependent only upon the reflex function of the Spinal cord. The experiments afforded the same results, when made upon each class of Vertebrate animals.* The results obtained by other observers are not quite in accordance with those of Flourens. Dalton and Weir Mitchell found that in pigeons from which the greater part or the whole of the Cerebellum had been removed, and which survived the immediate effects of the operation, recovery took place after the lapse of some months, so far that the animal only exhibited feebleness and incapacity for prolonged muscular exertion, but no real want of co-ordination or unsteadiness of equilibrium. Experiments of this kind made on Mammals are attended with so much injury as to prove invariably fatal; but Combetti† has recorded a case of congenital absence of the Cerebellum in a girl who could stand and walk up to a short period before her death, but who was noticed to fall frequently. Wagner found that the chief symptoms produced in Pigeons from which he had removed the whole or the greater part of the Cerebellum were—1. A remarkable tendency on the part of the animal to throw itself on one side, and to keep the legs completely extended, with an indisposition to move them, though it was still evidently capable of flexing them by an effort of the will. 2. Torsion of the head on the neck. 3. Persistent trembling of the muscles of the body generally, resembling *paralysis agitans*. 4. Vomiting frequently accompanied by liquid alvine evacuations; and 5. The animals became thinner, the feathers fell off, and the temperature was much depressed. No symptoms were observed having reference to the generative organs. The perception of sensations and the performance of psychical operations appeared to be perfect; and though the voluntary control over the muscles was somewhat impaired, it was manifestly not altogether lost. Ferrier‡ notes that when the Cerebellum is divided exactly in the middle line in an antero-posterior direction, the disturbances of equilibrium, if any, are of no marked importance, and there is none of the tendency to reeling or rotation which characterizes undefined lesion of the organ. Injury of the anterior part of the middle lobe of the Cerebellum is followed, in the monkey, by a tendency to fall forwards, whilst after lesion of the posterior part there is a tendency to fall backwards, and this last disposition is observed in cases of disease of the middle lobe. Lussana observes that the results of irritation of the Cerebellum are usually vomiting, cephalalgia, convulsions, and affections of the pupil, strabismus, amblyopia, &c.; and he believes that in every case of extensive disease of the Cerebellum there are concurrent symptoms of disorder of the muscular movements, indicative of defect or absence of the "muscular sense."

503. It was further affirmed by Magendie, that the removal of the Cerebellum, or the infliction of a deep wound in its substance on both sides, occasions the animal to move *backwards* as if by an irresistible impulse,

* They have been since repeated, with nearly corresponding effects, by Bouillaud, Hertwig, and by many other experimenters. See Wagner, in Brown-Séquard's "Journal de la Physiol.," 1861, pp. 225 and 404; Lussana in idem, 1862, p. 418, 1863, p. 170; MM. Leven and Ollivier, "Archiv. Gén. de Méd.," Nov. and Dec. 1862; Dalton, "American Journal of Med. Science," 1861, vol. xli. p 83; Brown-Séquard, "Central Nervous System," 1860; Vulpian, "Leçons sur la Physiologie du Système Nerveux," 1866; Ferrier, "The Functions of the Brain," 1876, p. 85. † "Révue Médicale," 1831. ‡ Loc. cit., p. 93.

and this he attributed to the retrograde power of the Corpora striata, which now acts without its due balance. That such a movement does *sometimes* present itself after such injuries as have been described, cannot be questioned, the fact having been confirmed by other experimenters; but it is a phenomenon of such rarity, that it cannot be rightly considered as having any direct dependence upon the injury of the Cerebellum, but must be rather set-down to some accidental complication or concurrent disturbance; more especially since, as already pointed out, the function attributed by Magendie to the Corpora striata has no real existence.—But the results of section of one of the Crura cerebelli, which were first obtained by Magendie, are much more constant; for the performance of this operation causes the animal to fall-over upon one side, and to continue *rolling upon its longitudinal axis*, even as fast (in some instances) as sixty times in a minute, the movement going on for many days without intermission. The rotation is accompanied by a remarkable deviation of the eyes. The eye on the side of the lesion looks downwards and inwards, while the eye of the sound side looks upwards and backwards. There is a remarkable difference in the statements of different experimenters, however, as regards the direction of this rolling movement; for whilst Magendie and Müller affirm that it takes place *towards* the injured side, Longet and Lafargue assert that it takes place *from* the injured side towards the opposite side. This discrepancy appears, from the experiments of Schiff,* to be due to a difference in the locality of the section; for he states that if the peduncle be divided from *behind*, the animal turns *towards* the side in which the section is made; whilst if the section be made *in front*, the animal turns *from* that side towards the opposite one. The difference is explained by Longet, by the difference in the course of the anterior and posterior fibres of the peduncles: for, according to him, the former communicate with the decussating, and the latter with the non-decussating portion of the motor tract; so that, when the former are injured, the animal loses control over the muscles of the opposite side, and when the latter, over the muscles of the same side. This rolling movement is attributed by some to the continued activity of the muscles on one side, now unbalanced by that of the muscles on the other; but if such were the case, as Longet justly remarks, it ought to occur more frequently than it does in cases of ordinary hemiplegia; and, according to that experimenter, observation shows that it rather depends on a *twisting* movement of the muscles attached to the spinal column, especially affecting its anterior portion, and dragging the posterior (as it were) after it.† Thus M. Brown-Séquard,‡ who has shown that similar rolling movements may be produced by lesions of other parts of the nervous centres, as the Spinal cord, Medulla oblongata, and Pons, observes that the movements do not resemble those effected by voluntary muscles; but that, in consequence of the tonic contraction into which some muscles are thrown, the trunk and neck of the animal are twisted as far as the bones will permit, into the form of a corkscrew. He attributes the phenomena in question, which the animal evidently endeavours to check, to the irritation of a peculiar set of nerve-fibres not usually employed by the will, the division of which does not cause paralysis, though they may serve as the conductors of powerful motor impulses to special groups of muscles. MM. Leven and Ollivier, operating on guinea-pigs, found that puncture of the Cerebellum produced well-marked movements of rotation, usually proceeding from the side injured

towards the opposite side. They did not observe any disorders of the alimentary canal similar to those noticed by Wagner and others, after ablation of portions of the Cerebellum. In his experiments on the effects of electrical stimulation of the Cerebellum in Monkeys, Ferrier found that irritation of the pyramid of the median lobe caused both eyes to turn to the side on which the stimulus was applied. Irritation of the posterior part of the upper vermiform process caused both eyes to look straight downwards. Irritation of the left side of the superior vermiform process (*declive monticuli*) caused both eyes to move downwards and to the left; irritation of the right side, downwards and to the right. Proceeding still further forwards, stimulation of the anterior extremity of the superior vermiform process in the middle line caused both eyes to move directly upwards; stimulation on the left side, both eyes upwards and to the left, without rotation; stimulation on the right side, both eyes upwards and to the right, without rotation. Stimulation of the lateral lobe on the left side caused both eyes to move upwards and to rotate to the left; on the right side it caused both to move upwards and to rotate to the right. Stimulation of the flocculus caused both eyes to rotate on their antero-posterior axes. Besides these ocular movements, certain movements of the head and limbs were produced, the movements of the head coinciding generally in direction with those of the eyes.*

504. The information supplied by Pathological phenomena, when interpreted with the cautions formerly referred to, is found on the whole to coincide with that obtained from experiment. In the first place, it fully supports the conclusion, that the Cerebellum is not in any way the instrument of *psychical* operations. Inflammation of the membranes covering it, if confined to that part, does not produce delirium; and its almost complete destruction by gradual softening does not appear necessarily to involve loss of intellectual power. "But," remarks Andral, "whilst the changes of intelligence were variable, inconstant, and of little importance, the lesions of motion, on the contrary, were observed in all the cases [of softening] except one; and in this it is not quite certain that motion was not interfered with." Yet the result of Andral's analysis of as many as ninety-three cases of disease of the Cerebellum,† is not favourable to the doctrine to which the results of experiments seem to point; but, as it has been justly remarked by Longet, the effects of disease are only partly comparable to those of experiment; since in a large proportion of chronic disorders, the changes consist in the formation of a new product, such as a tubercular or cancerous deposit, or a cyst of some kind, the gradual development of which is quite consistent with the continued functional activity of the organ, as we see by parallel phenomena elsewhere; whilst in those instances in which hæmorrhage occurs, this usually occasions either complete apoplexy or local paralysis, by its effects upon other organs. Still, several cases of chronic disease of the Cerebellum have been observed, in which *unsteadiness of gait*, without paralysis, or only giving place to paralysis at last on the occurrence of hæmorrhage, was a very marked symptom;‡ and these afford a strong confirmation of the doctrine based on the experimental researches already referred to. In a few cases in which both lobes of the Cerebellum have been seriously affected, the tendency to retrograde movement has been observed; and instances are also on record of the occurrence of

* The observations made by Hitzig, loc. cit., are very similar to those made by Ferrier.

† See his "Clinique Médicale," 2ème édit. tom. v. p. 735.

‡ Two such cases are recorded by Mr. Dunn in the "Med.-Chir. Trans.," vol. xxxii., and another by Dr. Cowan in the "Prov. Med. and Surg. Journ.," April 16, 1845; and the Author has been made acquainted with several others, by gentlemen under whose cognizance they have fallen. See also various papers by Hughlings Jackson in "Med. Times and Gazette."

rotatory movement, which has been found to be connected with lesion of the Crus cerebelli on the same side.* So far as they can be relied on, therefore, the results of the three methods of investigation bear a very close correspondence, and lead to the conclusion well expressed by Ferrier, that the Cerebellum is a complex arrangement of individually differentiated centres, which in associated action regulate the various muscular adjustments necessary to maintain the equilibrium of the body; each tendency to the displacement of the equilibrium round a horizontal, vertical, or intermediate axis acting as a stimulus to the special centre which calls into play the antagonistic or compulsory action.

505. It must not be allowed to pass unnoticed, that some Physiologists (as Foville, Pinel-Grandchamp, and Dugès) have regarded the Cerebellum as the centre of common sensation; chiefly on the ground of its connection with the posterior columns of the Spinal cord, and of the manifestations of pain which are called-forth by touching the Restiform columns. Although these facts may lead us to admit that the Cerebellum is connected with the sensorial centres, and even that it is itself *a* seat of sensibility, yet it is impossible to regard it as the exclusive seat of sensibility, consistently with the facts with which experiment and pathological observation supply us; since neither the removal of the entire organ by operation, nor its complete destruction by disease,† has been found to involve any loss of the ordinary sensorial powers. —There would seem much more probability in the idea, that it is the special seat of the "muscular sense," which has so important a share in the guidance of the co-ordinated movements (§ 492); and this notion derives confirmation from the marked structural connection which exists between the Cerebellum and the Optic ganglia (corpora quadrigemina), the purpose of which may be not unfairly surmised to be, to communicate the guidance of the *visual* sense to the organ by which the co-ordination of motions is effected, in the same manner as the impressions appertaining to the 'muscular sense' are transmitted upwards by the Restiform columns.‡ The chief objection to such a view, would seem to lie in the strong similarity between the 'muscular' sense and 'common' or 'tactile' sensation, which makes it difficult to conceive that they should have different seats in the *Sensorium commune*. But this difficulty is diminished if not removed by the reflection, that the Restiform columns appear to have the same endowments as the remainder of the Sensory tract derived from the posterior columns of the Spinal cord; and that no explanation can be given of their extreme sensitiveness to impressions (as shown by experiment), unless it be admitted that the organ in which they terminate is itself a centre of a form of sensation closely allied to that of the common or tactile kind. Possibly, however, the true termination of these fibres is in the 'corpus dentatum' of the Crura cerebelli; and the Cerebellum may react upon impressions thence transmitted to it, without being itself the instrument of communicating such impressions to the consciousness.§ Dr.

* A collection of such cases has been made by Dr. Paget, in his Paper on 'Morbid Rhythmical Movements,' in the "Edinb. Med. and Surg. Journal," 1847, vol. lxvii.—A case once fell within the Author's knowledge, in which a state of this kind, that lasted for some hours, appeared to depend upon an attack of Indigestion; the symptoms being completely relieved by vomiting, and no further indication of Encephalic disorder manifesting itself.

† See the well-known case recorded by Combetti, in the "Revue Médicale," t. ii. p. 57.

‡ This view, suggested many years since by the Author, has been recently supported in the able papers by M. Ph. Lussana in the "Journal de la Physiologie," tom. v. 1862, p. 484, and tom. vi. p. 169; and also by Mr. Robert Dunn, in his "Essay on Physiological Psychology" (London, 1858), who also places the centre of the muscular sense in the corpus rhomboidale of the Cerebellum.

§ M. Brown-Séquard ("Journ. de la Physiol.," vol. i. 1858, p. 535) and Wagner (Op. cit.)

Laycock* states that the consideration of a large and varied series of facts have led him to the conclusion that the Cerebellum with its connection downwards along the medulla oblonganta and spinal cord, and upwards into the hemispheres, is the great trophic centre. This centre may be excited to functional activity, not only by afferent impressions from the body, whether consciousness be coincident or not, but also by afferent impressions from the vast periphery of the cerebral hemispheres, and in this case also whether consciousness be coincident or not; in short, that the cerebral hemispheres are not functionally restricted to intellectual processes, as is generally held, nor the cerebellum to muscular co-ordination, but that both conjointly influence the whole of the organic processes.

506. We have now to examine, however, another doctrine regarding the functions of the Cerebellum, which was first propounded by Gall, and which is supported by the Phrenological school of physiologists. This doctrine, that the Cerebellum is the organ of the sexual instinct, is not altogether incompatible with the other; and by some it has been held in combination with it. The greater number of Phrenologists, however, regard this instinct as the *exclusive* function of the Cerebellum; and assert that they can judge of its intensity by the degree of development of the organ. We shall now examine the evidence in support of this position, afforded by the three methods of inquiry which have been already indicated.—In the first place it may be remarked, that the sexual propensity is very closely connected with various emotional states of mind, to which 'organs' are assigned by Phrenologists, and of which the Cerebellum is universally admitted to be the seat; such for instance as 'love of offspring,' 'adhesiveness,' and (in the lower animals more particularly) 'combativeness;' whilst in man it has a continual operation upon the reasoning faculties and the will. Yet the anatomical connections of the Cerebellum are peculiarly unfavourable to any such influence; these being, as we have seen, rather with the lower than with the higher portion of the Cerebro-spinal axis.—Again, the results of fair observation as to the com-

have arrived at almost purely negative results in regard to the function of the Cerebellum. The former experimenter holds that this organ is not a nervous centre for sensitive impressions nor for consciousness, nor is it even a part through which the conductors of motion or of sensation pass; for he believes that no idea, emotion, or voluntary act is suppressed as a consequence of lesion of its structure. Hence he maintains, that it is not a centre for the faculty of balancing or co-ordination of the symmetrical movements of the body, and that when paralysis is observed after lesion of its structure, it is occasioned (when the paralysis is on the opposite side of the body) by concurrent lesions of other parts, as the Pons Varolii, the Medulla oblongata, or the Cerebral peduncles; whilst, when the paralysis is on the same side, it is *usually* due to *irritation* of certain parts of the Cerebellum reacting on other parts of the Encephalon, though even from this cause the paralysis may sometimes occur on the opposite side. Though he does not admit it to be a centre for auditory or visual impressions, he acknowledges that it has a special influence on vision, having collected sixty cases of amaurosis accompanying disease of its structure. (See also on this point the works of Lussana, Luys, and Renzi.) He has, in a more recent paper ("Journ. de la Phys.," 1862, tom. v. p. 486), attributed the various effects of Cerebellar lesion, as amaurosis, vomiting, cephalalgia, dilatation of the pupil, general or local convulsive movements, epilepsy, hemiplegia, general debility and disordered movements, contraction of particular muscles, strabismus, hyperæsthesia, noises in the ears, and exaggeration of the sexual desire, to *irritation* of the Cerebellum, and not to *loss of function*. He compares these effects with those produced by worms in the intestines. Wagner believes that this organ may become the *point de départ* of a direct (not reflex) irritation for certain organic muscles, as for those of the abdominal viscera, generative organs, and also, probably, for the heart. Lussana concludes the Essay already quoted, by observing that the *muscular sense* and the *erotic sense* are the two essential functions of the Cerebellum. Prideaux, "Med. Times and Gaz.," 1864, vol. ii. p. 340, adduces evidence to show that the lateral lobes are the centres of cutaneous sensibility, whilst the central lobe is the centre of muscular sensibility.

* "Med. Times and Gaz.," July 12, 1873.

parative size of the Cerebellum in different animals, can scarcely be regarded as otherwise than very unfavourable to the doctrine in question.*—It is asserted, however, that the results of observation in Man lead to the positive conclusion, that the size of the Cerebellum is a measure of the intensity of the sexual instinct in the individual. This assertion has been met by the counter-statement of others, that no such relation exists. It is unfortunate that here, as in many other instances, each party has registered the observations favourable to its own views, rather than those of an opposite character; so that until some additional evidence of a less partial nature shall have been collected, we must consider the question as *sub judice*. It may be safely affirmed, however, that no evidence upon the affirmative side of this proposition has yet been adduced, which can be in the least degree satisfactory to the mind of any Physiologist who is competent to judge of its value. For nearly all the observations which have been paraded by Phrenologists in support of Gall's doctrine, have been based, *not* upon the actual *determination* of the size or weight of the Cerebellum in different individuals, but upon an *estimate* of its proportional development from the external conformation of the skull. Now any one who has even cursorily examined those principal types of cranial conformation which are characteristic of some of the chief sub-divisions of the Human species, must perceive that there is a no less characteristic difference between these different types in the occipital than there is in the frontal region. For whilst the occipital projection is much *greater* in the 'prognathous' skull than it is in the 'elliptical,' it is as much *less* in the 'pyramidal;' and thus while the first would be considered, according to phrenological rules, to hold a much larger Cerebellum, this organ in the latter would be regarded as necessarily very small. Now there is not only as much evidence of a strong development of the sexual propensity, in the characters and habits of the pyramidal-skulled Asiatics, as there is in regard to the elliptical-skulled Europeans, or the prognathous Negroes; but there is also anatomical evidence to show that the *size of the Cerebellum in the different races bears no relation whatever to the degree of projection of the occiput;* for the plane of this organ being somewhat oblique in the elliptical skull, is horizontal in the prognathous, and nearly vertical in the pyramidal, while the size and anatomical relations of the organ are not in the least degree affected by this difference in its position.†—Hence it may be safely affirmed, that no evidence with regard to the relation asserted to exist between the size of the Cerebellum and the intensity of the sexual propensity, has any value, save that which is drawn from the positive determination of the former by measure or weight.

507. Among the arguments adduced by Gall and his followers in proof of the connection between the Cerebellum and the sexual instinct, is one which would deserve great attention, if the facts stated could be relied on. It has been asserted, over and over again, that the Cerebellum, in animals which have been castrated when young, is much smaller than in those which have retained their virility—being, in fact, *atrophied* from want of power to act. Now it is unfortunate that vague assertion, founded on estimates formed by the eye from the cranium alone, is all on which this position rests; and it will be presently shown how very liable to error such an estimate must be. The following is a result of a series of observations on this subject, suggested by M. Leuret,‡ and carried into effect by M. Lassaigne:—The *weight* of the

* See "Brit. and For. Medical Review," vol. xxii. pp. 535–541.

† The Author's statements on this point are based on the very decided assertions of his late friend Prof. Retzius of Stockholm, who paid special attention to this inquiry.

‡ "Anat. Comp. du Système Nerveux," tom. i. p. 427.

Cerebellum, both absolutely and as compared with that of the Cerebrum, was adopted as the standard of comparison. This was ascertained in ten Stallions, of the ages of from nine to seventeen years; in twelve Mares, aged from seven to sixteen years; and in twenty-one Geldings, aged from seven to seventeen years. The average weight of the Cerebrum in the *Stallions* was 433 grammes; the greatest being 485 gr., and the least (which was in a horse ten years old) being 350 gr. The average weight of the Cerebellum was 61 gr.; the greatest being 65 gr., and the least 56 gr. The average proportion borne by the weight of the Cerebellum to that of the Cerebrum, was, therefore, 1 to 7·07; the highest (resulting from the very small Cerebrum) being 1 to 6·25; and the lowest (resulting from an unusually large Cerebrum) being 1 to 7·46. Throughout it might be observed, that the variation in the size of the Cerebellum was much less than in that of the Cerebrum.—In the twelve *mares*, the average weight of Cerebrum was 402 gr.; the highest being 432 gr., and the lowest 363 gr. That of the Cerebellum was 61 gr.; the highest being 66 gr. (which was in the individual with the smallest Cerebrum), and the lowest 58 gr. The average proportion of the weight of the Cerebellum to that of the Cerebrum was 1 to 6·59; the highest being 1 to 5·09, and the lowest 1 to 7. The proportion was, therefore, considerably higher in the perfect female than in the perfect male.—In the twenty-one *Geldings*, the average weight of the Cerebrum was 419 gr.; the highest being 566 gr., and the lowest 346 gr. The average of the Cerebellum was 70 gr.; the highest being 76 gr., and the lowest 64 gr. The average proportion was, therefore, 1 to 5·97; the highest being 1 to 5·16, and the lowest 1 to 7·44. It is curious that this last was in the individual which had the largest Cerebellum of the whole; but the proportional weight of the Cerebrum was still greater.—Bringing together the results of these observations, they are found to be quite opposed to the statement of Gall. The weight of the Cerebrum, reckoning the Cerebellum as 1, is thus expressed in each of the foregoing descriptions of animals:—

	Average.		*Highest.*		*Lowest.*
Stallions	7·07	...	7·46	...	6·25
Mares	6·59	...	7·00	...	5·09
Geldings	5·97	...	7·44	...	5·16

The average *proportional* size of the Cerebellum in Geldings, therefore, is so far from being *less* than that which it bears in entire Horses and Mares, that it is positively greater; and this depends not only on diminution in the relative size of the Cerebrum, but on its own larger dimensions, as the following comparison of *absolute* weights will show:—

	Average.		*Highest.*		*Lowest.*
Stallions	61	...	65	...	56
Mares	61	...	66	...	58
Geldings	70	...	76	...	64

The difference is so remarkable, and appears, from examination of the individual results, to be so constant, that it cannot be attributed to any accidental circumstance arising out of the small number of animals thus examined. The average weight of the Cerebellum in the ten Stallions and twelve Mares is seen to be the same, and the extremes differ but little in the two; whilst the average in the Geldings is more than one-seventh higher, and the *lowest* is considerably above the *average* of the preceding, while the highest far exceeds the highest among the entire Horses. It is curious that Gall would have been much nearer the truth if he had said that the dimensions of the

Cerebrum are usually reduced by castration; for it appears from the following Table that such is really the case:—

	Average.	*Highest.*	*Lowest.*
Stallions	433	485	350
Mares	402	432	336
Geldings	419	566	346

The weight of the largest Cerebrum of the Gelding is far above the highest of the Stallions, but it seems to have been an extraordinary case, as in no other was the weight above 490 gr. If this one be excluded, the *average* will be reduced still further, being then about 412; this may be seen, by looking over the whole Table, to give a very fair idea of the usual weight in these animals, which is therefore *less*, by about one-twentieth, than the average in the Stallion.—The increased size of the Cerebellum in Geldings may perhaps be accounted for, by remembering that this class of horses is solely employed for its muscular power, and that the constant exercise of the organ is not unlikely to develop its size; while Stallions, being kept especially for the purpose of propagation, are much less applied to occupations which call forth their motor activity.

508. It is asserted, however, by the followers of Gall, that very strong evidence of the truth of this doctrine is afforded by Pathological phenomena: excitement of the genital organs, manifesting itself in priapism, turgescence of the testes, and seminal emissions, being an ordinary concomitant of some forms of apoplexy in which the Cerebellum is affected; whilst in other cases of disease or injury involving extensive destruction of the substance of the organ, there has been a complete abatement of sexual desire. The proportion of recorded cases of disease of the Cerebellum, however, in which any affection of the genital organs has been noticed, is extremely small; for out of 178 cases which have been collected by Burdach,* only 10, or scarcely more than 1 in 18, presented any symptoms that tended to indicate a functional relation between the Cerebellum and the Genital organs. The same physiologist affirms that similar affections present themselves when the Cerebrum is the seat of the lesion; and there seems a strong probability that it is solely to the connection of these organs with the Spinal cord, that such affections of the genital apparatus are due. For erection of the penis has been noticed in a far larger proportion of cases in which the Spinal cord itself has been the seat of the lesion; thus in 15 cases in which the cervical portion of the Cord was affected, erection of the penis was observed in 8; and in 13 cases of lesion of the dorso-lumbar portion of the Cord, erection of the penis took place in 3.† It is well known that erection of the penis and emissio seminis are not infrequent phenomena of death by hanging; and this fact accords fully as well with the idea that the affection of the sexual organs is consequent upon lesion of the Cranio-spinal axis, as with the doctrine that it is due to disordered functions of the Cerebellum.—It has been suggested by Serres,‡ who collected seven cases in which excitement of the genital organs was coincident with apoplexy of the median lobe of the Cerebellum, that while the lateral lobes or hemispheres may be connected with the locomotor function, the median lobe may be the organ of the sexual instinct. Several cases have been recorded in which some such relation appeared to be indicated; and the Author has been made acquainted with at least six§ in which

‡ "Anatomie Comparée du Cerveau," tom. ii. pp. 601, 717.

§ Four such cases came under the notice of his friend, the late Dr. Simpson, of York.

an extraordinary salacity developed itself at an advanced period of life, whilst, concurrently with this, or following upon it, there was that kind of unsteadiness of gait which may be held to indicate chronic disease of the Cerebellum. In one of these cases of which the history and post-mortem appearances have been carefully recorded by Mr. Dunn,* there was strong evidence that the excitement of the sexual propensity was coincident with the irritative stage of incipient disease in the central lobe of the Cerebellum, and that the abatement of the propensity was in like manner coincident with the subsequent destruction of its substance; whilst the advance of the disease into the lateral lobes was marked by impairment of the power of co-ordination of movement. But with regard to all such cases, and others that may be ranked in the same category,† the objection of Pétrequin‡ holds good, that when disease or injury affects the median lobe of the Cerebellum, the Medulla oblongata is almost certain to be implicated in it; so that, as the evidence already referred to clearly indicates the existence of a special relation between the genital organs and the upper part of the Spinal axis, no positive proof is afforded by them that any portion of the Cerebellum has any special connection with the generative function.

509. The Author is far from denying *in toto* that any peculiar connection exists between the Cerebellum and the Genital system; but if the evidence at present adduced in support of the Phrenological position be held sufficient to establish it, in defiance of so many opposing considerations, we must bid adieu to all safe reasoning in Physiology. The weight of testimony appears to him to be quite decided, in regard to the connection of the Cerebellum with the regulation of the motor function; and as an additional argument in favour of this view, it may be stated, that the lobes of the Human Cerebellum undergo their most rapid development during the first few years of life, when a large number of complex voluntary movements are being learned by experience, and are being associated by means of the muscular sensations accompanying them; whilst in those animals which have, immediately after birth, the power of regulating their voluntary movements for definite objects, with the greatest precision, the Cerebellum is more fully developed at the time of birth. In both instances it is well formed and in active operation (so far as can be judged of by the amount of circulation through it), long before the sexual instinct manifests itself in any perceptible degree.—But neither doctrine need be maintained altogether to the exclusion of the other; and there are many among the Phrenologists of the present day, who hold, with Serres, that whilst the *hemispheres* of the Cerebellum possess the endowments now generally assigned to them by Physiologists, the *central lobe* is connected with the Genital function. If has been shown by Dr. N. S. Davis,§ however, that there is no perceptible difference in the dimensions of this central lobe, any more than in those of the hemispheres, between Bulls and Oxen; and no proof has yet been offered,

* "Medico-Chirurgical Transactions," vol. xxxii.

† Thus, a case has been communicated to the Author by Mr. Turley, of Worcester, in which the sexual desire, which had been always strong through life, but which had been controlled within the limits of decency, manifested itself, during a period of some months preceding death, in a most extraordinary degree; on *post-mortem* examination, a tumour was found on the Pons Varolii.—And he has been informed of another case by Dr. Evanson (formerly of Dublin), in which a young officer on the eve of marriage, having received a blow on the occiput by a fall from his horse, became impotent, without any other disorder of his bodily or mental powers; and in the distress consequent upon this discovery, committed suicide on the morning fixed for his wedding.

save that afforded by the pathological evidence just referred to, that any such endowment is possessed by it. That in some way or other, however, either the central portion of the Cerebellum, or some part of the Medulla oblongata, has a special connection with the Generative function, appears to the Author to be indicated with tolerable clearness by several of the Pathological phenomena already cited. The circumstance, too of which he has frequently been assured, that great application to gymnastic exercises diminishes for a time the sexual vigour, and even totally suspends desire, seems worthy of consideration in reference to such a view; for if the Cerebellum be really connected with both kinds of function, it does not seem unreasonable that the excessive employment of it upon one should diminish its energy in regard to the other. —An analysis of the nature of the Sexual propensity, however, suggests the conclusion that we are not to look in this part of the Encephalon for anything else than a seat of the sexual *sensation;* the character of which seems to be sufficiently different from that of mere *tactile* sensation, to require a distinct ganglionic centre. Such a centre would be likely to be placed in the line of the other sensory ganglia, and in close connection with them.

510. As in the case of other sensations, the Sexual, when moderately excited, may give rise to ideas, emotions, and desires, of which the Cerebrum is the seat; and these may react on the muscular system through the Intelligence and Will. But when inordinately excited, or when not kept in restraint by the Will, the sexual sensations will at once call into play respondent movements which are then to be regarded as purely automatic. This is the cause in Nymphomania and Satyriasis in the Human subject; and it is probably also the ordinary mode of operation of this sense, in such of the lower animals as have not psychical power enough to form a conception of an absent object of gratification, and cannot, therefore, be said to have sexual *desires*. Thus, like other sensations, it may act either *intelligently* or *automatically;* giving rise to *ideas*, by transmission to the Cerebrum, which ideas, associated with pleasurable feelings, originate *desires* that stimulate the Reasoning powers to devise means for their gratification, and excite the Will to the necessary actions; or, by its immediate action upon the motor-apparatus, producing respondent *movements*. —Of this double *modus operandi* we seem to have sufficient evidence. For among many of the lower tribes of animals, at the time when the generative organs are in a state of functional activity, the presence of an individual of the opposite sex indicated by the sight, smell, hearing, or touch, immediately excites the whole train of instinctive actions concerned in the reproductive operation; whilst we have no evidence in them of any voluntary exertion, resulting from the existence of a desire entertained in the absence of the object, and intended for the gratification of that desire. In Man, on the other hand, the principal operation of the sexual sensations is in awakening desires and affections, which serve as excitements to the intelligence and as motives to the Will; and it is only, under ordinary circumstances, when the two sexes have been thus brought into close relation, that the direct reaction of the sexual sensation manifests itself in automatic movements. In cases, however, in which this sensation is excited in unusual strength, it may completely overmaster all motives to the repression of the propensity, and may even entirely remove the actions from volitional control; and a state of a very similar kind exists in many Idiots, in whom the sexual propensity exerts a dominant power, not because it is in itself peculiarly strong, but because the Intelligence being undeveloped, it acts without restraint or direction from the Will.

5. *The Cerebrum, and its Functions.*

511. We come, in the last place, to consider the functions of that portion of the Nervous Centres which is evidently, in Man, the predominant organ of his whole system; being not merely the instrument of his Reasoning faculties, but also possessing a direct or indirect control over nearly all the actions of his corporeal frame, save those purely vegetative processes which are most completely isolated from his animal powers. We should be in great danger, however, of coming to an erroneous conclusion as to the real character of the Cerebrum and of its operations, if we confined ourselves to the study of the Human organism; and the history of Physiological science shows that every advance of knowledge respecting its functions has tended to *limit* them, whilst at the same time rendering them *more precise*. Thus the Brain (this term, in the old Anatomy, being chiefly appropriated to the Cerebrum) was once accounted not merely the centre of all motion and sensation, but also the source of all vitality; the different processes of nutrition, secretion, &c., being maintained, it was supposed, by a constant supply of 'animal spirits,' propagated from the brain, along the nerves, to each individual part. The more modern doctrine, that the Sympathetic System has for its special function to supply the nervous influence requisite for the maintenance of the functions of Organic life through its action on the blood-vessels, was the first step in the process of limitation; still the Brain was regarded as the centre of all the Animal functions, and no other part was admitted to possess any power independently of it. By experiments and pathological observations, the powers of the Spinal cord as an independent centre of action were next established; and it was thus shown that there is a large class of motions in which the Brain has no concern, and that the removal of the Cerebral hemispheres is not incompatible (even among the higher Vertebrata) with the prolonged maintenance of a sort of inert and scarcely conscious life. Still, it has been usually maintained, and with great show of reason, that the Cerebrum is the instrument of all *psychical* operations, and the originator of *all* the movements which could not be assigned to the reflex action of the Spinal cord. An attempt has been made, however, in the preceding pages, to show that this view is not correct; and that there is a class of actions, neither excito-motor nor voluntary, but directly consequent upon Sensations, and constituting (with the excito-motor) the truly *instinctive* actions, which may be justly assigned to certain ganglionic centres not less independent of the Cerebrum than is the Spinal cord itself. It has been further pointed out that the Cerebrum must be considered in the light of an organ *superadded* for a particular purpose or set of purposes, and not as one which is essential to life; that it has no representative among the Invertebrata (except in a few of the highest forms, which evidently present a transition towards the Vertebrate series); and that, at its first introduction in the class of Fishes, it clearly performs a subordinate part in the general actions of the Nervous System. Hence, whatever be the function, or set of functions, we assign to the Cerebrum, we must keep in view the *special* character of the organ; and we must never lose sight of the fact, that its predominance in Man does not deprive other parts of their independent powers, although it may keep the exercise of those powers in check, and may considerably modify their manifestations.

512. Before proceeding to inquire into the Physiology of the Cerebrum we may advantageously take notice of some of the leading features of its structure.*

* For further details of the minute anatomy of the Cerebral substance, see Lockhart Clarke in the "Proceedings of the Royal Society," vol. xii. No. 57. Luy's "Leçons sur la Structure du Systéme Nerveux," 1875. Hoffmann-Schwalbe, "Lehrbuch der Neurologie," 1880.

In the first place, it forms an exception to the general plan on which the elements of ganglionic centres are arranged, in having its vesicular substance on the *exterior*, instead of in the *central* part of the mass. The purpose of this is probably to allow the vesicular matter to be disposed in such a manner as to present a very large *surface*, instead of being aggregated together in a more compact mass; and by this means to admit, on the one hand, a more ready access of the blood-vessels which are so essential to the functional operations of this tissue, as well as a more ready communication, on the other, with the vast number of fibres by which its influence is to be propagated. There is no reason whatever to believe, that the relative functions of the vesicular and fibrous substances are in the least altered by this change in their relative position; indeed, the results of observation upon the phenomena of disordered Cerebral action are such as to afford decided confirmation of the doctrine now generally accepted, that the action of the Vesicular matter constitutes the *source* of nervous power, whilst the Fibrous structure has for its office to *conduct* the influence thus generated to the points at which it is to operate. The purpose of this arrangement is further evidenced by the fact, that, in all the higher forms of Cerebral structure, we find a provision for a still greater extension of the surface at which the vesicular matter and the blood-vessels may come into relation; this being effected by the plication of the layer of vesicular matter into 'convolutions,' into the sulci between which the highly vascular membrane known as the 'pia mater' dips down, sending multitudes of small vessels from its inner surface into the cortical substance. The convolutions of the Brain* are extremely complicated in their arrangement, but they can be divided into groups by certain easily recognized fissures, and are individually identified and named. The more important of them only need be described here. The outer and under surface of each hemisphere is divided into five lobes as follows. Tracing the deep Sylvian fissure outwards upon the external aspect of the hemisphere it is seen to bifurcate, one branch running upwards, the other almost horizontally backwards. Anterior to the Sylvian fissure we have the *frontal lobe*, between its two branches the *parietal lobe*, below the posterior branch the *temporo-sphenoidal lobe*, and forming the posterior extremity of the hemisphere the *occipital lobe*, while concealed within the Fissure of Sylvius is the *central lobe*, more commonly known as the Island of Reil. This last presents a few short and almost straight gyri radiating from the inner end of the fissure called the *Gyri operti*. The four other lobes are each made up of three more or less tortuous gyri. The frontal convolutions have a horizontal direction, and form three tiers, named respectively the *superior*, *middle*, and *inferior frontal* convolutions, the superior close to and parallel with the great longitudinal fissure, the inferior resting upon the orbital plate of the frontal bone. It is the posterior part of this inferior frontal convolution which has been said to be the seat of the faculty of language, and disease here to be one of the causes of aphasia. The convolutions of the parietal lobe are nearly vertical, and run up to the margin of the longitudinal fissure; between the first or anterior and the second is a well-marked sulcus, which appears early in the development of the brain, and is called the Fissure of Rolando. The temporo-sphenoidal gyri are again almost horizontal, lying parallel to the horizontal branch of the Sylvian fissure. The occipital lobe is small and not well-defined, a series of short irregular convolutions connecting it with the parietal lobe. These have received the name of annectent or bridging gyri; the

A is the supra-marginal lobule; B is the postero-parietal lobule; and β is on the bridging or annectent convolutions; R, fissure of Rolando; E, parieto-occipital fissure.

* For accurate descriptions of which see Prof. Turner's Pamphlet, 1866; Gratiolet, "Sur les Plis Cérébraux de l'Homme," &c., 1854; L. Marshall on the 'Brain of a Bushwoman,' &c., "Proc. Roy. Soc. 1863;" Quain and Sharpey's "Anatomy," vol. ii. p. 531; and Ecker's pamphlet "On the Convolutions of the Brain."

convolutions of the occipital lobe itself are irregularly horizontal, and its anterior limit is a sulcus which issues from the longitudinal fissure, and is called the parieto-occipital fissure. On the opposed flat surfaces of the hemispheres the principal convolutions seen are the *marginal convolutions*, which form the margin of the great longitudinal fissure and the *gyrus fornicatus*, which encircles the corpus callosum, commencing anteriorly near the anterior perforated space, and terminating at the point of the temporo-sphenoidal lobe. By some anatomists these two great convolutions have been subdivided.

513. The *Cortical* substance or 'grey matter' of the Hemispheres essentially consists of that *vesicular* nerve-substance, which, in the Spinal cord, as in ganglionic masses generally, is found to occupy the interior. Its usual thickness is about one-fifth of an inch; but considerable variations present themselves in this respect, as also in the depth of the convolutions. Thus, the plications are deepest, and the layer of 'grey matter' the thickest, during the period of greatest nervous energy, that is, in middle life; in infancy and in

old age, the convolutions are simpler and have fewer undulations, and the thickness of their cortical substance is much inferior; and the same is true of the adult brain of some of the least cultivated races of mankind. The structure of the cortical substance has been most carefully investigated by Mr. Lockhart Clarke.* The convolutions present on section at least seven layers of nervous substance, the concentric arrangement of which is most conspicuous at the extremity of the posterior lobe, and is rendered apparent by a slight

* See "Proceed. of Roy. Soc.," vol. xii. No. 57, and Dr. Maudsley's "Physiology and Pathology of the Mind," 1868, p. 60, from which last the account in the text is taken. A good description of the structure of the brain is also given by Arndt in Schultze's "Archiv," Band iii. p. 441, 1867. See also Cleland, "Quart. Journ. of Microscop. Sci.," 1870, p. 126; and Meynert, in Stricker's "Human and Comp. Histology," vol. ii. p. 382; Gerlach, "Centralblatt," 1872, p. 273; Rindfleisch, "Centralblatt," 1872, p. 277; Lewis and Clarke, "Proceed. Roy. Soc.," vol. xxvii. 1878, p. 38.

difference in hue. In this situation all the nerve cells are small, but differ considerably in shape, and are much more abundant in some layers than in others. In the *superficial* layer (Fig. 244), which is pale, they are round, oval, fusiform, or angular, but not numerous. The *second* layer is darker, and is densely crowded with cells of similar form and size, mingled with others that are *pyriform* and lie with their tapering ends either towards the surface or parallel with it, in connection with fibres which run in a corresponding direction. The broader ends of the pyramidal cells give off two or more processes which run partly towards the central white axis of the convolutions, and partly horizontally along the plane of the layer. The *third* layer is of a much paler colour. It is crossed at right angles by narrow and elongated groups of small cells and nuclei, intermediate to which are bundles of fibres radiating towards the surface from the central white axis of the convolutions. The *fourth* layer contains broader and more regularly arranged groups of cells and nuclei, which together with the bundles of fibres between them, present a distinctly fan-like arrangement. The *fifth* layer is pale, with a similar structure, but with the fan-like appearance less distinct. The *sixth* layer is reddish-grey, and contains similar cells to those above described, with others that are rather larger. The elongated groups of cells are fewer in number. Its deep surface blends with the central white axis of the convolution, into which its cells are scattered for some distance. The *seventh* layer is the central white stem or axis of the convolution, which gives off on every side bundles of fibres that radiate outwards, becoming exceedingly fine as they reach the surface, in consequence of some of the fibres terminating in the cells of the different layers, whilst others bend round and run horizontally, either crossing the convolution transversely, or running longitudinally in the same direction. Besides these fibres which form the central white axis of the convolution, another set springing from the same source converge or rather curve inwards from opposite sides to form arches along some of the grey layers. They appear to be partly continuous with those of the radiating or divergent set which bend round to follow a similar course. All these fibres establish an infinite number of communications in every direction, between different parts of each convolution, between different convolutions, and between these and the central white substance. In other central convolutions situated more anteriorly, the layers are less pronounced, and instead of *all* the cells of the several layers being small, a certain proportion of much larger cells are found chiefly occupying the two internal layers. These cells are pyramidal, with quadrangular bases directed towards the central white substance, and each gives off four or more processes which run partly towards the central white axis, and partly parallel with the surface of the convolution to be continuous with arciform fibres. The processes frequently subdivide into minute branches, which form part of the network between them. The apical extremity runs straight outwards, and gives off minute branches which are lost like the process itself in the surrounding network. Slight modifications occur in the vesicular structure of other convolutions. It is interesting to note that Mr. Clarke was unable to perceive any difference whatever between the cells of the convolutions in Man and those of the ape tribe.

Professor Meynert, in an elaborate essay, has recently given an anatomical description of the brain, of which the following is an outline. Many points, however, are here unavoidably omitted, especially those relating to the structure of the medulla oblongata and pons, for which the reader is referred to the original article contained in the second volume of Stricker's "Manual of Histology," translated for the Sydenham Society.

Prof. Meynert points out that the peripheric nerves of the body collectively converge towards the grey matter of the cerebral cavities, spinal cord, and medulla oblongata, and that after

passing through these with more or less interruption or segmentation in the ganglion cells, they diverge to terminate in the great expansion of grey substance which forms the cortex of the cerebral hemispheres. The entire collection of fibres he terms the "Projection system," and commences its description, not with the peripheric nerves, but from the hemispheres of the cerebrum and cerebellum. He divides it into three links, with three masses of grey matter. The first mass of grey matter is the cortex of the cerebrum, and cerebellum (C, Fig. 245), and the first link of the projection system is represented essentially by the corona radiata (1, 2, 3, and 4) which consists of fibres extending from the cerebral cortex to the ganglionic masses of the corpus striatum and optic thalamus, which constitute the second mass of grey matter. The *second link* of the projection system is composed of fibres that extend from these ganglia to the grey substance around the central cavities, which is the third grey mass, and is represented by the system of the crus cerebri (5, 7, 8). The *third link* is formed by the *nerves* which arise from the above-named grey substance of the central cavities, beginning with the origin of the third pair of cerebral nerves in the grey matter around the aqueduct of Sylvius to the nucleus of origin of the lowermost coccygeal nerve of the spinal cord.

Speaking generally, the cortex of the cerebrum presents five laminæ (Fig. 244). The first is principally composed of an equably punctated matrix, with a few small stellate cells, and near its surface numerous fine varicose nerve-fibres decussating in all directions. The second is a layer of close-set, small pyramidal corpuscles; the third is a layer of large pyramidal corpuscles; the fourth is a layer of small, close-set, irregular shaped corpuscles, and the fifth is a layer of fusiform corpuscles. The matrix, Meynert considers consists chiefly of a non-nervous substance. It has been called ependyma formation by Rokitansky, neuroglia by Virchow, connective tissue by Kölliker, coalesced ganglion cell-substance by Henle and R. Wagner, gelatinous substance by Clarke, and molecular substance by Kupffer.

Fig. 244.

Layer of large pyramidal corpuscles. 4. Layer of small, close-set, irregularly-shaped, cortical corpuscles (granule-like formation). 5. Layer of fusiform cortical corpuscles. *m*. Medullary layer.

The different parts of the same hemisphere are connected, first, by the numerous intercommunicating processes of the cells; and secondly, by a system of arcuate fibres of different lengths lying immediately beneath the cortex (a a, c c). The corresponding parts of the *opposite* hemispheres are connected by the transverse fibres of the corpus callosum. The cortex of the cerebrum is connected with that of the cerebellum by fibres passing directly from one to the other.

The *corpus striatum* consists of two nuclei—the caudate or intra-ventricular nucleus (Cs, Fig. 245)—and an extra-ventricular one, named the lenticular nucleus (Nl). The caudate nucleus is essentially connected with the olfactory lobe and bulb by connecting fibres, and is consequently small in man as compared with many animals.

The fibres forming the *first link of the projection system*, are—1. Those proceeding from the internal surface of the whole length of the cerebral hemisphere, but chiefly from the frontal lobes to the *lenticular nucleus*. 2. The stria cornea proceeding from the apex of the temporal lobe to the anterior region of the corpus striatum. 3. The fibres entering the *optic thalamus*—namely, *a*. Those arising from the frontal lobe and passing straight back between the caudate and lenticular nuclei of the corpus striatum (5, Fig. 245). *b*. Those proceeding from the walls of the Sylvian fissure and from the temporal lobes (inferior peduncle of optic thalamus). *c*. Fibres from the stria zonalis; and lastly, *d*. Those proceeding from the cortex of the gyrus fornicatus, constituting the ascending pillar of the fornix (or superior peduncle of optic thalamus). The fornix itself is the projection fasciculus of the cortex passing to the anterior eminence of the optic thalami.

The deeper-lying part of the *optic thalamus* receiving the corona radiata contains many cells, and constitutes the red nucleus of the tegmentum. This red nucleus is the first internode of a tract that originates in the cortex of the cerebrum in a fan-like form, and stretches to the cortex of the cerebellum. The processus a cerebello ad cerebrum is a free segment of this connecting tract between the two layers of cortical substance. Beneath the above-mentioned fan is a second more slender fan of the corona radiata, which is applied to the substance of Soemmerring. Posteriorly the optic thalami are connected with the

optic tracts. The optic tracts are also connected just as if they were a portion of the corona radiata with the brachium of the inferior corpus quadrigeminum. The optic tracts and nerves, therefore, are not peripheric nerves, but the retina, like the olfactory bulb, is, so to speak, an outlying portion of the cortex cerebri.

Fig. 245.

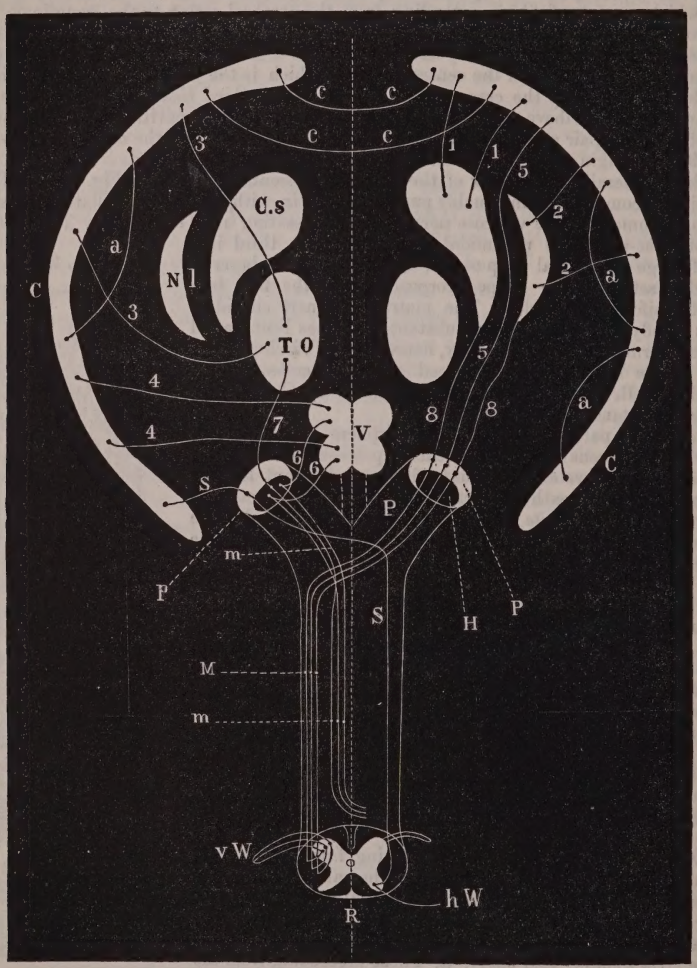

Diagram of the structure of the brain. C C, cortical substance of the cerebral hemispheres; C. s, corpus striatum; N. l, nucleus lenticularis; T. O, thalamus opticus; V, corpora quadrigemina; P, pedunculus cerebri; P, basis or crusta, and H, tegmentum; 1, 1, fibres of the corona radiata of the corpus striatum; 2, 2, those of the lenticular nucleus; 3, those of the optic thalamus; 4, 4, those of the corpora quadrigemina; 5, 5, direct strands to the cortex cerebri (Flechsig); 6, fibres from the corpora quadrigemina to the tegmentum; 7, fibres from the optic thalamus to the tegmentum; *m*, further course of these fibres; 8, fibres from the corpus striatum and lenticular nucleus to the pes of the pedunculus cerebri; M, further course of these fibres; S, S, course of the sensory fibres; R, transverse section of the spinal cord; v W, anterior roots; h W, posterior roots of the spinal nerves; a, a, association fibres; c, c, commissural fibres.

The second link of the projection system is formed by the system of the crura cerebri, which is divided into two layers with some intermediate grey substance. The inferior or anterior layer named the *crusta*, proceeds from the corpus striatum; the superior or posterior layer named the *tegmentum*, chiefly from the optic thalamus. In addition to the fibres proceed-

ing from the two nuclei of the corpus striatum, the crusta contains others derived from the substantia nigra of the ventricles and fibres which come directly from the occipital and temporal lobes. The size of the cerebral hemispheres, of the lenticular nucleus, and of the crusta cerebri, are all proportionate to one another, but there is no relation between the size of the crusta and of the tegmentum. On the contrary, the tegmentum of the crus with its ganglia, especially the corpora quadrigemina, and corpora geniculata interna, are more largely developed in proportion to the smallness of the cerebral lobes. The tegmental fibres proceeding from the optic thalamus are reinforced by others from the posterior commissure—the anterior and posterior corpus geniculatum, the cortex cerebelli, and the pineal gland, those from the latter source decussating with those of the opposite side. The innermost fibres of the crusta, after decussating in the middle line, terminate peripherally in the central grey substance of the ventricle surrounding the aqueductus Sylvii in the nates, penetrating at this point into the nucleus common to the third and fourth nerves. The most external fasciculus of the crusta passes through the decussation of the pyramids of the medulla oblongata, into the posterior column of the spinal cord.

The tegmentum is characterized by its connection with the optic tracts and fifth pair of nerves on the one hand, and with the motor columns of the spinal cord on the other, forming a region where sensory impressions are reflected as motor impulses. The fact that the ganglia of the crusta have no connection with sensorial peripheric expansions, suggests that they owe their power of exciting motor impulses to another source—namely, to the conditions of excitation of the cerebral lobes.

The organization of the crusta is completed near the anterior part of the thalamus. That of the tegmentum just below the corpora quadrigemina, the lowest of its ganglia of origin.

A large group of the radiating fibres proceeding from the occipital lobes converge to the ganglia of origin of the tractus opticus—*i.e.*, the external and internal corpora geniculata, and the corpora quadrigemina, forming a remarkably thick medullary lamina (optic radiations of Gratiolet). This mass associates itself with the posterior and *external* fasciculi of the *crusta* of the crus cerebri. But the most *external* fasciculus of the crusta, as just stated, passes through the decussation of the pyramids of the medulla oblongata, into the *posterior column* of the spinal cord, and consequently the posterior roots of the spinal nerves are represented in the same lobes of the hemispheres as the radiations of the optic tract. It is remarkable that these lobes also receive the fibres proceeding from the olfactory bulb and lobe. Another group of fibres from the cortex pass to the corpora quadrigemina, forming the brachia of the nates and testes.

The pineal gland is a ganglion of origin of the tegmentum, and is placed over the decussation of the tegmenta of the opposite sides.

At the level of the pons is a large and important region where the brachia of the cerebellum interlace with the projection system, and from this point the third link of the projection system descends. The superior peduncle is composed partly of fibres of the corona radiata, proceeding directly from the cortex of the cerebral hemispheres, and partly of the fibres from the optic thalamus and corpus striatum, all of which decussate so that the superior peduncles form a horseshoe closed in front which corresponds with the nates and testes. They constitute the *connecting* system of the cerebellum. The middle peduncle of the cerebellum is best understood by remembering that every fasciculus of the crusta terminating in the anterior division of the pons is represented by two fasciculi of the opposite middle peduncle of the cerebellum, of which one runs through the superficial, the other through the deep layer of transverse fibres of the pons.

The inferior peduncle of the cerebellum consists of fibres passing from the cerebellum to the posterior columns of the spinal cord, and includes—1. The corpus restiforme; 2. The internal division of the inferior crus cerebri, and 3. The fasciculus cuneatus and slender fasciculus.

The grey substance of the central cavities is a centre from which a large number of nerve-roots take origin. It lines the third ventricle, surrounds the aqueduct of Sylvius, expands itself in the cavity of the fourth ventricle, and encloses the central canal throughout the spinal cord; from it the third, fourth, and succeeding cerebral, and all the spinal nerves in succession take origin, and these constitute the third link of the projection system. The third nerve may in fact be taken as the type of the projection system of Meynert. The first link consists of fibres extending from the cerebrum to the lenticular nucleus; the second link from the lenticular nucleus to the nucleus of origin of the third nerve in the grey substance of the third ventricle of the opposite side, and the third link being the nerve itself.

The cerebellum represents a loop or sling, the curves and sinuosities of which establish very indirect connections between the cerebrum and the nerve-roots. The auditory nerve is almost entirely lost in it, and it has extensive connections with the optic nerve. The crusta of the cerebral peduncle, which descending, is continued into the pyramids of the medulla oblongata, is at least three times the size of the pyramids, and this diminution is due to the termination of many of the fibres of the crusta in the ganglion cells of the pons, from whence fibres arise

that pass into the middle peduncles of the cerebellum. A motor function must therefore be attributed to the cerebellum, even from this point of view alone. For no other view can be taken than that the impulses conducted from the cortex to the corpus striatum and the lenticular nucleus, besides their conduction into the spinal cord, at the same time give rise to definite modes of activity of the cerebellum.

The medulla oblongata consists of a prolongation of the anterior and posterior tracts of the crus cerebri, and of the crus cerebelli, together with much scattered grey matter in its substance, and a layer on its surface, the grey matter of the fourth ventricle representing the grey matter of the central cavities.

514. The weight of the entire Encephalon in the adult Male usually ranges between 40 and 68 oz., the average being about 50 oz.; and in the Female from 36 to 50 oz., the average being about 45 oz.* The maximum of the healthy brain seems to be about 64 oz., and the minimum about 31 oz. But in cases of Idiocy, the amount is sometimes much below this; as low a weight as 20 oz. having been recorded.—It appears, from the investigations of M. Bourgery, that the relative sizes of the different component elements of the Human Encephalon are somewhat as follows:—Dividing the whole into 204 parts, the weight of the Cerebrum will be represented by about 170 of those parts; that of the Cerebellum by 21, and that of the Medulla oblongata with the Optic thalami and Corpora striata by 13. The weight of the Spinal cord would be, on the same scale, 7 parts. Hence the Cerebral hemispheres of Man include an amount of nervous matter which is *four* times that of all the rest of the Cranio-spinal mass, more than *eight* times that of the Cerebellum, *thirteen* times that of the Medulla oblongata, &c., and *twenty-four* times that of the Spinal cord.—The absolute weight of the cerebral hemispheres varies according to Meynert from 17,000 to 21,600 grains. The average weight of the whole Encephalon in proportion to that of the body, in Man, taking the average of a great number of observations, is about 1 to 36. This is a much larger proportion than that which obtains in most other animals; thus the average of Mammalia is stated by M. Leuret to be 1 to 186, that of Birds 1 to 212, that of Reptiles 1 to 1321, and that of Fishes 1 to 5668.† It is interesting to remark, in reference to these estimates, that the Encephalic prolongation of the Medulla oblongata in Man (being about one-sixteenth of the weight of the whole Encephalon) is *alone* more than twice as heavy in proportion to his body as the *entire* Encephalon of Reptiles, and ten times as heavy as that of Fish.—But there are some animals in which the weight of the Encephalon bears a higher proportion to that of the body than it does in Man; thus in the Blue-headed Tit, the proportion is as 1 to 12, in the Goldfinch as 1 to 24, and in the Field-mouse as 1 to 31. It does not hence follow, however, that the *Cerebrum* is larger in proportion; in fact, it is probably not nearly so large; for in Birds and Rodent Mammals, the Sensory ganglia form a very considerable proportion of the entire Encephalon. M. Baillarger has shown that the *surface* and the *bulk* of the cerebral hemispheres are so far from bearing any constant proportion to each other in different animals, that notwithstanding the depth of the convolutions in the Human Cerebrum, its bulk is $2\frac{1}{2}$ times as great in proportion to its surface as it is in

* The average of both sexes differs, however, in the various races of mankind. Dr. Davis ("Proceedings of the Royal Society," Jan. 23rd, 1868) found the mean of the European series to be 46·87 oz.; of the Asiatic series, 44·62 oz.; of the American series, 44·73 oz.; of the African series, 44·3 oz.; and of the Australian series, 41·38 oz. Dr. Thurnam ("Journal of Mental Science," April, 1866) gives 49 oz. as the average weight of the European brain, whilst in distinguished men it amounts to 54·6 oz.

† In the pike the proportion is as 1 to 1300; in the horse 1 to 800; elephant 1 to 500; sheep 1 to 350; dog 1 to 110; pigeon 1 to 104. See Munk, "Archiv f. wiss. u. prakt. Thierheilkunde," Band vi. 1880, p. 73. For the influence of stature on the weight of the encephalon in man, see Marshall, "Proceed. Roy. Soc.," June 17, 1875.

the Rabbit, the surface of whose Cerebrum is smooth. The entire surface of the human Cerebrum is estimated by him at about 670 square inches. In all estimates of the weight of the Brain in Man, it is important to take the influence of stature into consideration. Professor Marshall has shown that an increase of stature is accompanied by an increase in the absolute but not in the relative weight of the brain. Taking both sexes together, the total increase, with a mean range of 11 inches between the highest and the lowest group of individuals examined, is about $6\frac{3}{4}$ oz. avoirdupois (=191·25 grammes); in males, with a mean range of 7 inches, it is $2\frac{3}{4}$ oz.; in females, with a range of 6 inches, it is $1\frac{1}{4}$ oz.; the Cerebrum in both increasing absolutely more than the Cerebellum. Further investigation, however, showed to him that this increase does not take place *pari passu* with the stature, but that, on the contrary, there is a gradual and progressive relative diminution in the proportion of Encephalic substance to the stature as this latter itself increases. Hence short persons of either sex have, proportionally to their height, a larger amount of brains than taller ones. Nevertheless, the proportion is larger in the male than in the female, not only generally but even at corresponding heights—as for example in short men as compared with tall women. This, as Mr. Marshall observes, is interesting, as evidence that the well-known sexual difference in the weight of the male brain overrides the influence of stature, or subsists in spite of his greater stature, which has a tendency to diminish his proportionate amount of brain. The specific gravity of the Brain has been made the subject of careful research by Dr. Bastian, who finds the average of the grey substance to be 1·030 and of the white 1·040.

515. The Encephalon altogether receives a supply of Blood, the amount of which is very remarkable, when its comparative bulk is considered; the proportion which goes to it being, according to the estimate of Haller, as much as one-fifth of the whole mass. The manner in which this blood is conveyed to the brain, and the conditions of its distribution, offer some peculiarities worthy of notice. The two Vertebral and two Carotid arteries, by which the blood enters the cavity of the cranium, have a more free communication by anastomosis than any similar set of arteries elsewhere; and this is obviously destined to prevent an obstruction in one trunk from interrupting the supply of blood to the parts through which its branches are chiefly distributed—the cessation of the circulation through the nervous matter being immediately productive of suspension of its functional activity.*—Not only must there be a sufficient supply of blood, but it must make a regulated pressure on the walls of the vessels. Now the Encephalon is differently circumstanced from other vascular organs, it being enclosed within an unyielding bony case; and we find a special provision for equalizing the bulk of the contents of this cavity, and for counterbalancing the results of differences in the functional activity of the brain and in its supply of blood, in the existence of a fluid which is found beneath the arachnoid, both on the surface of the brain and spinal cord, and in the ventricles of the former. The amount of this 'cerebro-spinal-fluid'† seems to average about two ounces; but in cases of atrophy of the brain, as much as twelve ounces of fluid may sometimes be obtained from the cranio-spinal cavity; whilst in all instances in which the bulk of the brain has undergone an

* M. Robin ("Journal de la Physiologie," vol. ii. p. 537) has described an accessory tissue around the capillaries of the brain, in the space between which and the proper tunica adventitia, free nuclei, fatty masses, and granules of hæmatosin, are observable. M. Robin seems to be of opinion that these are the lymphatics of the brain. See also Stricker in idem, 1867, p. 652.

† For a full discussion of the value and uses of the cerebro-spinal fluid see Hilton, "Rest and Pain," ed. Jacobson, 2nd ed., 1877, sects. ii. and iii.

increase, whether from the production of additional nervous tissue, or from undue turgescence of the vessels, there is either a diminution or a total absence of this fluid. It appears from the experiments of Magendie (to whom our knowledge of its importance is chiefly due), that its withdrawal in living animals causes great disturbance of the cerebral functions, probably by allowing undue distension of the blood-vessels; it is, however, capable of being very rapidly regenerated, and its reproduction restores the nervous centres to their natural state.—As the cerebro-spinal fluid can readily find its way from the sub-arachnoid spaces of the *cranial* cavity into those of the *spinal*, and as it is no less readily absorbed than reproduced, it evidently serves as an equalizer of the amount of pressure within the cranial cavity; admitting the distension or contraction of the vessels to take place, within certain limits, without any considerable change in the degree of compression to which the nervous matter is subjected. That this uniformity is of the greatest importance to the functional exercise of the brain, is evident from a few well-known facts. If an aperture be made in the skull, and the protruding portion of the brain be subjected to pressure, the immediate suspension of the activity of the whole organ is the result; in this manner, a state resembling profound sleep can be induced in a moment, the normal activity being renewed *as* momentarily so soon as the pressure is withdrawn.* This phenomenon has often been observed in the Human subject in cases in which a portion of the cranial envelope has been lost by disease or injury. The various symptoms of cerebral disturbance which are due to a state of general Plethora, are evidently owing to an *excess* of pressure within the vessels; but an undue *diminution* of pressure is no less injurious, as appears from the disturbance in the cerebral functions which results from the very opposite cause—namely, a depression of the power of the heart, or a deficiency of blood in the vessels.—It is of peculiar importance to bear in mind the disturbance of the cerebral functions occasioned by variations of internal *pressure*, when we are endeavouring to draw inferences from the phenomena presented by disease.

516. We shall now proceed with our Physiological inquiry into the functions of the Cerebrum; and shall appeal, as before, to Human and Comparative Anatomy, to Experiment and to Pathology, for our chief data.—The anatomical relations of the Cerebrum to the other Encephalic centres, clearly demonstrate that it is not one of the essential or fundamental portions of the Nervous system; but a superadded organ, receiving all its impulses to action from the parts below, and operating upon the body at large through them. And its great bulk, joined to its position at the summit of the whole apparatus—the vesicular substance of its convolutions affording a termination to the fibres in connection with it, and not being for the most part only traversed by them, as is the case with that of all the lower centres—clearly mark it out as the highest in its functional relations, and as ministering, so far as any material instrument may do, to the exercise of those psychical powers, which, in Man, exhibit so remarkable a predominance over the mere animal instincts. This conclusion is fully borne out, when we extend our inquiries from Human to Comparative Anatomy; for with some apparent exceptions which there would probably be no great difficulty in explaining if we were in possession of all the requisite data, there is a very close correspondence between the relative development of the *Cerebrum* in the several tribes of Vertebrata,† and the degree of *Intelligence* they respectively possess—using

* Schiff states that the Indian snake-charmers are accustomed to produce rigidity of the body in these animals by pressure on the occiput.

† See "Princ. of Comp. Phys.," § 662 *et seq.* For numerous instances of "Intellect in Brutes," see "Nature," 1879.

the latter term as a comprehensive expression of that series of mental actions which consists in the *intentional* adaptation of means to ends, based on definite *ideas* as to the nature of both. It is not always easy to say, in the case of the lower animals, what parts of their actions are to be attributed to automatic impulse (*i.e.*, to be considered as Instinctive), and what should be regarded as the results of Intelligence. The character of Intelligent actions, however, as compared with Instinctive, is usually shown (1) in the *variety* of means which are adopted to compass the same ends, and this not merely by different individuals and by successive generations, but by the same individual at different times; (2) by the improvement in the mode of accomplishing the object, which results from the intelligent use of experience, and from the greater command of means which is progressively attained; and (3) by the conformity of the means to altered circumstances, so that the character of adaptiveness is still maintained, however widely the new conditions may depart from those which must be considered as natural to the species.

517. The difference between actions which proceed from the Intellectual faculties prompted by the instinctive propensities, and those of a purely Instinctive character, is well seen in comparing Birds with Insects. The Instinctive tendencies of the two classes are of nearly the same kind; and the usual arts which both exhibit in the construction of their habitations, in procuring their food, and in escaping from danger, must be regarded as intuitive, on account of the uniformity with which they are practised by different individuals of the same species, and the perfection with which they are exercised on the very first occasion. But in the adaptation of their operations to peculiar circumstances, Birds display a variety and fertility of resource, far surpassing that which is manifested by Insects; and it can scarcely be doubted by those who attentively observe their habits, that in such adaptations they are often guided by real intelligence. This must be the case, for example, when they make trial of several means, and select that one which best answers that purpose; or when they make an obvious improvement from year to year in the comforts of their dwelling; or when they are influenced in the choice of a situation by peculiar circumstances, which in a state of Nature can scarcely be supposed to effect them. The complete domesticability of many Birds is in itself a proof of their possessing a certain degree of intelligence; but this alone does not indicate the possession of more than a very low amount of it; since many of the most domesticable animals are of the humblest intellectual capacity, and seem to become attached to Man, principally as the source on which they depend for the supply of their animal wants. But there are certain tribes of Birds, especially the Parrots and their allies, which possess an extraordinary degree of *educability*, and which manifest a power of performing simple acts of *reasoning*, that are quite comparable with those of a child when first learning to talk.

518. This development of the Intelligence under the influence of Man, and in accordance with *his* habits rather than with the original habits of their species, is yet more remarkable in the case of those Mammals whose instincts lead them to attach themselves peculiarly to him, and whose powers of reasoning are called forth in adapting themselves to the new circumstances in which they are thus placed. The actions of a Dog, a Horse, or an Elephant are evidently the result, in many instances, of a complex train of reasoning, differing in no essential respect from that which Man would perform in similar circumstances; so that the epithet 'half-reasoning,' commonly applied to these animals, does not express the whole truth; for their mental processes are of the same *kind* with those of Man, and differ more in the *degree* of compre-

hensiveness of their data and conclusiveness of their inferences, than they do in their essential character. More evidence, however, than we at present possess is required to show that any of the lower animals have a voluntary power of *directing* their mental operations, at all similar to that which Man possesses; these operations, indeed, seem to be of very much the same character as those which we perform in connected dreams, different trains of thought commencing as they are suggested, and proceeding according to the usual law, until some other disturb them.—Although it is customary to regard the Dog and the Elephant as the most intelligent among the lower animals, it is not certain that we do so with justice; for it is very possible that we are misled by that peculiar attachment to Man, which in them must be termed an instinct, and which enters as a motive into a large proportion of their actions; and that, if we were better acquainted with the physical characters of the higher Quadrumana, we should find in *them* a greater degree of mental capability than we now attribute to them. One thing is certain, that the higher the degree of Intelligence which we find characteristic of a particular race, the greater is the degree of variation which we meet with with in the characters of individuals; thus everybody knows that there are stupid Dogs, and clever Dogs, ill-tempered Dogs, and good-tempered Dogs—as there are stupid Men and clever Men, ill-tempered Men and good-tempered Men. But no one could distinguish between a stupid Bee and a clever Bee, or between a good-tempered Wasp and an ill-tempered Wasp, simply because all *their* actions are prompted by an unvarying Instinct.

519. In estimating the relative development of the Cerebrum in different tribes of Animals, and in comparing this with their relative Intelligence, it must be borne in mind that the *size* of the organ does not, considered alone, afford a means of accurate judgment as to its *power*. For the quantity of vesicular matter which it contains, affords the only fair criterion of the latter; and of this we must judge, not merely by the superficial area, but by the number and depth of the convolutions, and by the thickness of the cortical layer.* Again, there are many reasons why it is not fair to estimate the relative development of the Cerebrum by the proportion which it bears to the whole bulk of the animal; and, on the whole, the most accurate basis of comparison would probably be afforded by the relation between the bulk of the Cerebrum and the diameter of the Spinal cord. In making any such comparison, however, the Thalami optici, Corpora striata, and Corpora quadrigemina should be excluded from the estimate, for reasons now sufficiently apparent; and the bulk of the Cerebrum *proper* should be alone determined, either by weight, or by the displacement of liquid.—But the Cerebrum varies in different classes and orders of Vertebrata, not merely in proportional size, but also in the relative development of its anterior, middle, and posterior lobes. This is a point of very great importance, in determining the value to be assigned to the organological system of Gall and Spurzheim and their followers. The Cerebrum of the Oviparous Vertebrata is *not* a miniature representative of that of Man, as a whole, but only of his *anterior* lobes; as is sufficiently obvious from an examination of its connections with other parts, and from the absence of any other commissural connections between its two hemispheres than those which are afforded by the Sensory ganglia. It is in the Non-placental Mammals that we find the first rudiments of the *middle* lobes of the Cerebrum, and of the proper inter-cerebral commissure, the Corpus callosum; and even in the Rodents this is but very imperfectly

* See for numerous observations bearing on this point, Bevan Lewis, "Brain," 1878, vol. i. p. 79, and Danilewsky, "Centralblatt f. d. Med. Wiss.," 1880, p. 241.

developed. As we ascend the Mammalian series, we find the Cerebrum becoming more and more elongated posteriorly by the development of the middle lobes, and the inter-cerebral commissure becomes more complete; but we must ascend as high as the Carnivora, before we find the least vestige of the *posterior* lobes; and the rudiment which these possess is so rapidly enlarged in the Quadrumana, that in some of that group the posterior lobes are as fully developed in reference to the Cerebrum as a whole, and as completely cover in the Cerebellum as in the Human subject.*—The attention which has yet been given to this department of inquiry, has not hitherto done more than confirm the statement already made, with regard to the general correspondence between the development of the Cerebrum and the manifestations of Intelligence; very decided evidence of which is furnished by the great enlargement of the Cerebrum, and the corresponding alteration in the form of the Cranium, which present themselves in those races of Dogs most distinguished for their educability, when compared with those whose condition approximates most closely to what was probably their original state of wildness.

520. This general inference, drawn from Comparative Anatomy, is borne out by observation of the Human species. When the Cerebrum is fully developed, it offers innumerable diversities of form and size among various individuals; and there are as many diversities of character. It may be doubted if two individuals were ever exactly alike in this respect. That a Cerebrum which is greatly under the average size is incapable of performing its proper functions, and that the possessor of it must necessarily be more or less idiotic, there can be no reasonable doubt. On the other hand, that a large well-developed Cerebrum is found to exist in persons who have made themselves conspicuous in the world in virtue of their intellectual achievements, may be stated as a proposition of equal generality. In these opposite cases we witness most distinctly the antagonism between the Instinctive and Voluntary powers. Those unfortunate beings in whom the Cerebrum is but little developed, are guided almost solely by their instinctive tendencies, which frequently manifest themselves with a degree of strength that would not have been supposed to exist; and occasionally new instincts present themselves, of which the Human being is ordinarily regarded as destitute.† On the other hand, those who have obtained most influence over the *understandings* of others, have always been large-brained persons, of strong intellectual and volitional powers, whose emotional tendencies have been subordinated to the reason and will, and who have devoted their whole energy to the particular objects of their pursuit.—It is very different, however, with those who are actuated by what is ordinarily

* It has been asserted by the followers of Gall, that the development of the Cerebrum from behind forwards, as above described, is rather apparent than real: the whole organ being in fact pushed backwards by the excessive development of the anterior lobe. But the anatomical distinction between the anterior and middle lobes is sufficiently obvious externally; and that of the middle and posterior lobes is also clearly marked out by the development of the posterior cornua of the lateral ventricles, and the situation of the hippocampus major. Hence the facts above stated do not admit of any such interpretation; and they are fully borne-out by the history of the Embryonic development of the Cerebrum in Man, which precisely follows the above plan.—It is not here denied that the anterior lobe of the Human Cerebrum is remarkable for its great extension *forwards;* but still, the difference between the Cerebrum of Man and that of the lower Mammalia consists much rather in the proportional development of the posterior lobes, than in that of the anterior.

† A remarkable instance of this was published some years since:—A perfectly idiotic girl, in Paris, having been seduced by some miscreant, was delivered of a child without assistance and it was found that she had *gnawed* the umbilical cord in two, in the same manner as is practised by the lower animals. It is scarcely to be supposed that she had any idea of the *object* of this separation.

termed *genius;* and whose influence is rather upon the *feelings* and *intuitions*, than upon the understandings of others. Such persons are often very deficient in the power of even comprehending the ordinary affairs of life; and still more commonly they show an extreme want of judgment in the management of them, being under the immediate influence of their passions and emotions, which they do not sufficiently endeavour to control by their intelligent will. The life of a 'genius,' whether his bent be towards poetry, music, painting, or pursuits of a more material character, is seldom one which can be held up for imitation. In such persons, the *general* power of the mind being low, the Cerebrum is not usually found of any great size.—The *mere* comparative size of the Cerebrum, however, affords no accurate measure of the amount of mental power; for we not unfrequently meet with men possessing large and well-formed heads, whose physical capability is not greater than that of others, the dimensions of whose crania have the same general proportion, but are of much less absolute size. Large brains, with deficient activity, are commonly found in persons of what has been termed the *phlegmatic* temperament, in whom the general processes of life seem in a torpid and indolent state; whilst small brains and great activity betoken what are known as the *sanguine* and *nervous* temperaments.

521. Having now inquired into the evidence of the *general* functions of the Cerebrum, which may be derived from the examination of its comparative development, we proceed to our other sources of information, Experiment and Pathological phenomena. The electric excitability of the hemispheres was first experimentally demonstrated by Fritsch and Hitzig,* who found that on the application of a constant current to particular regions of the surface of the hemisphere exposed by removal of the bone and *dura mater*, definite muscular movements occurred on the opposite side of the body, such as flexion, extension, and rotation of the limbs, and also movement of the facial muscles. Their earlier experiments were made on dogs, and the constant currents applied were feeble. They adduced various reasons against the supposition that the movements were due to mere conduction of the stimulus to distant centres, amongst the more important of which were the feebleness of the currents employed, the close approximation of the electrodes, the bad conductivity of the brain substance, the occurrence of contractions on the opposite side of the body, and their non-appearance when the position of the electrodes was slightly altered. In further researches, Hitzig† believed he was able to establish the existence of a distinct centre for the several movements of the eyes, coinciding with a part of the Facialis centre, and especially that part innervating the protective muscles of the eye, and he concluded from his experiments on monkeys that the anterior cerebral convolution constitutes the true motor part of the cortex of the cerebrum, the several centres lying in it from the median fissure downwards to the Sylvian fissure. The centre for the posterior extremity of the opposite side was about 3 mm. from the median line, and that for the anterior extremity about 3 mm. further outwards. Seven mm. beyond this laterally he placed the centre for a part of the muscles associated with the visual organs, and close to the Sylvian fossa he recognised a fourth centre governing the muscles of the mouth, tongue, and jaw of *both* sides. Weak currents applied to the parietal and frontal regions were not followed by any movements. He subsequently‡ found that lesion of the posterior convolutions (occipital) of the cerebral hemispheres produces blindness of the opposite eye and paralytic dilatation of the corresponding pupil. Soon after the appearance of the first

† Ibid., 1873, p. 397; and "Berliner Klin. Wochenschr.," 1874, No. 6.
‡ "Centralblatt f. d. Med. Wiss.," 1874, p. 548.

series of observations made by Fritsch and Hitzig, the results they obtained were confirmed and extended by Ferrier.* He defined on the surface of the brain of cats, dogs, and rabbits, the different centres from which various movements of the limbs, face, mouth and tongue, eyes, ears, &c., could be definitely and distinctly excited. The method of stimulation he employed was the direct application to the surface of the hemispheres of a pair of the blunted electrodes of the secondary spiral of Du Bois-Reymond's induction coil, connected with a cell of the mean electro-motor power of a single Daniell. The induced current generated in the secondary coil at eight centimeters distance from the primary coil was of a strength sufficient to cause a pungent but quite bearable sensation when the electrodes were placed on the tip of the tongue. Other observers have shown that similar effects can be produced by the employment of chemical stimuli. From the results of his experiments on monkeys, Ferrier† mapped out the following regions in their brain, the stimulation of which gives results which may thus be briefly stated (see Figs. 246, 247):—1. Movement of the hind foot as in walking; 2. Complex movements of the hind leg, con-

13
13

12. Eyes directed to the opposite side and upwards, with usually contraction of the pupils; 13. Similar action, but the eyes usually directed downwards; 14. Retraction of the opposite ear, head turning to the opposite side, the eyes widely opened and the pupils dilated; 15. Stimulation of this region, which corresponds to the tip of the uncinate convolution, causes torsion of the lip and nostril of the same side. The antero-frontal and occipital regions give no result on stimulation; nor does the island of Reil react to the stimulus. Thus it would appear that the *motor area* in monkeys includes the bases of the three frontal convolutions, with those bounding the fissure of Rolando—viz., the *ascending frontal* or anterior central (Ecker), the *ascending parietal* or posterior central (Ecker), and its upper continuation termed the *postero-parietal* or superior parietal lobule; together with the minor aspect of the same, usually named by the French the paracentral lobule. Ferrier* finds that removal or destruction by the cautery of the antero-frontal lobes is not followed by any definite physiological results. Monkeys thus operated on preserved their sensory faculties and powers of voluntary motion unimpaired, yet though not actually deprived of intelligence, they lost to all appearance the faculty of attention and intelligent observation. Destructive lesions of the motor area, on the other hand, invariably caused paralysis of voluntary motion. The existence of these areas seems to be unassailable. The application of a stimulus to them causes certain definite complex movements to occur. The application of the same stimulus to neighbouring parts does not produce those movements. Destruction of the areas by the actual cautery is followed by entire and permanent paralysis of the muscles by which the movements are effected, though the paralysed muscles may still be used in associated movements of other kinds. Stimulation of the corpora striata caused tonic spasm of the whole of the muscles of the opposite side, and consequently a condition of pleurosthotonos. Stimulation of the optic thalamus was negative.

522. Considerable difference of opinion exists among experimenters as to the real signification of the results thus obtained by galvanic or Faradic stimulation of the surface of the hemispheres. On the one hand, the movements may be regarded as being due to the stimulation of certain centres having definite functions situated in the grey matter of the cortex; whilst, on the other hand, they may be attributed to the conduction of the current to the motor ganglia, situated at the base of the brain. Dr. Burdon Sanderson,† for example, has shown that when the grey matter corresponding to the centres defined by Hitzig and Ferrier is removed, the same actions are produced by exciting the medullary fibres which proceed from these to the corpus striatum. But Ferrier‡ argues that the results cannot be explained by conduction, on the ground that in a state of anæsthesia sufficient to prevent any manifestation on stimulation of the surface of the brain, the corpora striata still remain excitable; whereas, unless it be assumed that chloroform annihilates the conductivity of the medullary fibres to the electric stimulus, the results should be obtained as before. The definiteness and predictibility of the results, the possibility of differentiating centres in close proximity to each other, and also the fact that stimulation of the island of Reil, which is near the corpus striatum, causes no action, even when the rest of the brain is excitable, seem to dispose of objections on the ground of conduction or diffusion. Ferrier further argues that as the corpus striatum contains in an integrated form the centres individually differentiated in the hemispheres, it is quite in accordance with the

† "Proceed. Roy. Soc.," 1873, June 11, 1874.
‡ "West Riding Asylum Reports," vol. iv. 1874.

explanation given by Hitzig and himself to suppose that stimulation of the medullary cone of fibres should excite the same movements as result from functional activity of the corresponding cortical centres. Many experimenters,* have noticed that the excitability of the fibres of the corona radiata is completely lost on the fourth day after the section, just as in the case of the peripheral segment of ordinary nerves separated from their centre. That the movements observed on the application of an electrical stimulus are not due to any mechanical irritation or shock is evident from the fact that chemical stimuli produce the same effect as the electrical current. Landois and others have† observed that stimulation of the cortical motor centres is inoperative in recently-born animals. The first movements that could be produced in puppies were in the fore-leg, and occurred on the tenth day. Stimulation of the corpus striatum was also without effect; yet stimulation of the *capsula interna*, or deep fibres of the zona radiata, produced movements of the opposite fore-leg even in the newly-born animal. The cortical areas are of wider extent at first than at a later period. François Franck and Pitres‡ have shown that a distinct interval elapses between the application of a stimulus to the brain and the movement induced by it—an interval amounting to about 1·22nd of a second when the requisite deductions are made for latent periods in nerve and muscle, and for the rate of transmission of nervous impulses in the cord and nerves. After removal of the grey matter, if the stimulus be applied to the medullary fibres, the period of retardation diminishes to about 1·33rd of a second, which proves that the grey matter constitutes not a conductor but a centre. Fritsch and Hitzig§ are of opinion that the cortical centres are related to the muscular sense, on the ground that after the ablation of the limb-centres in dogs, the animals so operated on do not suffer from paralysis of the limbs, but merely appear to have lost consciousness of the position of the limbs, and hence place them in irregular and unnatural attitudes. This view is also supported by Nothnagel from the results of his experiments in the injection of chromic acid into the brain cortex.‖ A very different view of the functions of the cerebral cortex is entertained by Goltz.¶ According to this observer, every part of the grey matter of the substance of the hemispheres participates in the exertion of the will, in the perception of sensations,

‖ Nothnagel (Virchow's "Archiv," Band lvii. p. 184, and lviii. p. 420) found on injecting a solution of chromic acid into a point about 14 mm. (half an inch) from the anterior extremity of the cerebral hemisphere in rabbits, and about 1-12th of an inch from the median fissure, that the opposite fore-paw dragged in walking, and could be placed in the most awkward positions without the animal resenting it, or attempting to withdraw it. It was, however, neither insensible nor paralyzed, it only appeared to have lost its muscular sense. A similar spot influencing both the fore and hind legs exists at the outer extremity of the gyrus post-frontalis. The affection is transitory, and disappears in a few weeks. Other motor paralyses were observed with injections made into various parts of the white substance. He finds a spot near the middle and inner part of the corpus striatum, which when injured leads in a course of a few minutes to violent leaping and springing forward movements, which continue for a quarter or half an hour till the animal drops exhausted; he terms this spot the *nodus cursorius*. Injury to a spot situated at the posterior extremity of the single sulcus of the brain of the rabbit is followed by similar springing movements, which after a few minutes cease entirely. Nothnagel found that ablation or destruction of the lenticular nucleus was followed by the same effects as removal of the cerebral hemisphere of the same side. See also Fournié, "Comptes Rend.," t. lxxvii. No. 5.

¶ Pflüger's "Archiv," 1879, p. 40; see also Hermann, idem, Band x.

in the conception of ideas, and in the exercise of thinking. Every segment, independently of the rest, is connected by strands with all the voluntary muscles, and by other strands or conductors with all the sensory nerves of the body. Goltz wholly denies the existence of small circumscribed and associated centres for the various groups of muscles or regions of the skin. The cortex of the brain acts as a whole, thinks as a whole, orders movements as a whole; though no doubt there are certain channels through which the influence of the will is conducted to the lower co-ordinating centres. He points out that in the case of the spinal cord, the structure and functions of which are far more simple than that of the brain, division temporarily abolishes the activity of the distant part, but that after a time, as may be observed in frogs and in dogs, the several reflex acts of micturition, defæcation, and even of those implicated in the performance of the sexual functions, are re-established—a result that is certainly not due to the reunion of the divided parts. The temporary failure of the functions of the lower segment after the operation of division, he attributes to an inhibitory influence being exerted on its grey matter by the irritation of the cut surface during the process of healing. But if this occur in the case of the spinal cord, much more is such an inhibitory influence likely to be exerted after ablation of large portions in an organ so complex as the brain. Hence, he argues, little weight is to be attached to the fact that paresis, or even abolition of the power of performing certain movements or of perceiving certain sensations, follows serious lesion of a particular region of the surface of the hemisphere. In many cases the effects observed are not constant, and even when well marked at first are quite transient; and he has satisfied himself that after extensive injury of various parts of the cerebral cortex, the animal does not lose special powers, as would be the case were there definite psychic centres, but is only rendered generally duller, less sensitive to external impressions, and more indisposed to exertion of any kind than before. The interpretation which Ferrier puts upon his experiments differs essentially from either of the foregoing. He regards the movements which result from stimulation as indications of excitation of centres concerned in voluntary or purposive action, or of centres of expression and sensation. The motor portion of the brain is situated anteriorly, and corresponds with the medullary expansion of the fibres from the corpus striatum, while the sensory portion corresponds with the medullary expansion from the optic thalamus. The destruction of a motor centre causes paralysis of voluntary motion in respect to the actions which are excited by stimulation of the same centre. This paralysis, however, is only complete in cases of movements which are quite independent of each other. It is seen more especially in the case of the monkey, which, like man, is capable of highly complex and independent movements. In dogs and quadrupeds generally, owing to the fact of the movements being automatically organized on both sides, the destruction of a motor centre in one hemisphere does not cause complete paralysis. Under the influence of the other hemisphere, or in response to sensory stimuli, action of both sides may be caused by the agency of the lower ganglia. Hence a dog may rapidly recover from the paralysis of motion, which manifests itself immediately after the destruction of the motor centres in the opposite hemisphere. This explanation is in accordance with the theory of Dr. Broadbent, who accounts for the fact that paralysis from brain disease affects the arm more than the leg, owing to the bilateral co-ordination in each hemisphere of movements usually associated together. Hence the motor centres in the brain are regarded by Ferrier as the differentiated apparatus of voluntary muscular action. At the same time they form what he terms the motor substrata of intellect, by being the centres of memory of muscular actions. Hence he

explains how the loss of speech is associated with the destruction of that part of the brain which is the centre for the movements of articulation.

523. As regards *sensory localization*, Ferrier, from a series of experiments on monkeys, claims to have localized the regions of special sense. These regions he regards as the centres of sensory perception, and as distinct from the centres for sensory impressions or sensori-motor action. The following is an abstract of these later researches, in which also attempts have been made to ascertain the functions of those parts of the hemispheres which do not react to stimulation:*—1. Ablation of the frontal regions which give no reaction to electrical stimulation is without effect on the powers of sensation or voluntary motion, but causes marked impairment of intelligence and of the faculty of attentive observation. 2. Destruction of the grey matter of the convolutions bounding the fissure of Rolando, causes paralysis of voluntary motion on the opposite side of the body; while lesions circumscribed to special areas in those convolutions, previously localized by the author, cause paralysis of voluntary motion, limited to the muscular action excited by electrical stimulation of the same parts. 3. Destruction of the angular gyrus (*pli courbe*) causes blindness of the opposite eye, the other senses and voluntary motion remaining unaffected. This blindness is only of temporary duration, provided the angular gyrus of the other hemisphere remain intact; when both are destroyed, the loss of visual perception is total and permanent.† 4. The effects of electrical irritation and the results of destruction of the superior temporo-sphenoidal convolution indicate that they are the centres of the sense of hearing. 5. Destruction of the hippocampus major and hippocampal convolution abolishes the sense of touch on the opposite side of the body. 6. The sense of smell (for each nostril) has its centre in the subiculum cornu Ammonis or tip of the uncinate convolution on the same side. 7. The sense of taste is localized in a region in close proximity to the sense of smell, and is abolished by destructive lesion of the lower part of the temporo-sphenoidal lobe. (The action is crossed.) 8. Destruction of the optic thalamus causes complete anæsthesia of the opposite side of the body. 9. Ablation of the occipital lobe produces no effect on the special senses or on the powers of voluntary motion, but is followed by a state of depression and refusal of food not to be accounted for by mere constitutional disturbance consequent on the operation. The function of these lobes is regarded as still obscure, but considered as in some measure related to the systemic sensations. Their destruction does not abolish the sexual appetite. 10. After removal both of the frontal and occipital lobes, an animal still retains its faculties of special sense and the power of voluntary motion. In the experiments made by the committee of the New York Society of Neurology and Electrology, including Drs. Dalton, Arnold, Beard, Flint, and Mason,‡ results confirmatory of Hitzig's observations were met with. They found that all the centres of motion for the anterior and posterior limbs are situated in the convolution immediately surrounding the frontal fissure which runs transversely to the longitudinal fissure. The centres for flexion and extension of the anterior and posterior limbs were always found in the external part of the præ-frontal convolution just anterior to this fissure, and in the post-frontal convolution just behind it. In a majority of cases, those for the anterior limbs were situated more in front, near the outer extremity of the frontal fissure, and those for the posterior limbs more posteriorly and inwards,

‡ "New York Med. Journ.," March, 1875.

but their exact positions varied somewhat in different cases. The centre for flexion of the head and neck in the median line is in the lateral and anterior part of the præ-frontal convolution, where it leads downwards and outwards; that for flexion of the head with rotation towards the side of the stimulus is in a part of the convolution situated still farther towards the front and downward, so as to be invisible in a view of the brain taken from above. The centre for the facial muscles is in a region situated on the lateral part of the hemisphere immediately above the supra-Sylvian fissure.* Munk† divides the brain of Dogs into an anterior or motor, and a posterior or sensory portion, separated from each other by a vertical line passing from the end of the fissure of Sylvius to the Falx. Lesion of the posterior superior extremity of the occipital lobe causes *psychic* blindness; lesion of the inferior part of the temporal lobe causes *psychic* deafness. In both instances there is loss of memory of the visual or auditory images, so that it no longer knows or recognizes what it sees or hears, though it does both see and hear. This condition, however, is only temporary. Munk thinks the visual sphere is localized in the cortex of the occipital lobes (and not, as Ferrier believes, in the angesta gyrus) in such a way that each retina is co-ordinated by its outermost and lateral part with the outermost and lateral part of the corresponding hemisphere. The remaining and much larger part of the retina lay associated with the vesical spleen of the cortex of the opposite occipital region. Eulenburg and Landois‡ and Hitzig§ have noticed that the ablation or destruction of regions in close proximity to Hitzig's and Ferrier's motor centres is followed by exaltation of temperature in the opposite hind-leg, which may amount to as much as 13° C. ($23\frac{2}{5}$° F.), and which may last for a day or two only, or may persist for three months. Electrical stimulation of this region lowered the temperature of the limbs of the opposite side. It thus appears probable that the mind can exert an influence upon the temperature of particular parts of the body.‖ It may also be noticed that strong stimulation of the motor centres of the extremities, according to Bochefontaine,¶ causes increase of the blood pressure in the arteries and retardation of the beats of the heart, and this occurs even after division of the vagi and sympathetics in animals.

524. The effects of the entire removal of the Cerebral Hemispheres have been already stated.** So far as any inferences can be safely drawn from them, these experiments fully bear out the conclusion that the Cerebrum is the organ of Intelligence; since the animals which have suffered this mutilation appear to be plunged in a profound sleep, from which no irritation ever seems able to rouse them into full activity, although they give manifestations of consciousness. It would be wrong hence to infer, however, as some have done, that such would be the natural condition of an animal without a Cerebrum; since it is obvious that much of the disturbance of the sensorial powers which is occasioned by this operation, is fairly attributable to the laying open of the cranial cavity, to the disturbance of the normal vascular pressure, and to the injury necessarily done to the parts which are left by their severance from the Cerebrum. Hence the persistence of consciousness after the entire removal of the Cerebrum—which

proves that the Cerebrum is *not* its seat, or at least *not its exclusive* seat—is a far more important fact than the positive destruction of psychical power which is consequent upon the operation. So far as they can be trusted, however, the results of such mutilations bear out the views already put forth, as to the superadded and non-essential character of the Cerebrum; and justify us in applying to the higher animals the inferences to which we should be led by the contemplation of those forms of the nervous system in which no Cerebrum exists. There is nothing, therefore, to oppose the conclusion, that whilst *sensations* may be felt, and sensori-motor actions excited, independently of the Cerebrum, the presence of this organ is essential to the formation of *ideas* or notions respecting the objects of sense, and to the performance of those psychical operations for which ideas furnish at once the material and the stimulus to activity.

525. The information afforded by Pathological phenomena is far from being definite.* Many instances are on record in which extensive disease has occurred in *one* Hemisphere, so as almost entirely to destroy it, without either any obvious injury to the mental powers, or any interruption of the influence of the mind upon the body. But there is no case on record of any such severe lesion of *both* hemispheres, in which morbid phenomena were not evident during life. It is true that, in Chronic Hydrocephalus, a very remarkable alteration in the condition of the Brain sometimes presents itself which might *à priori* have been supposed destructive to its power of activity; the ventricles being so enormously distended with fluid, that the cerebral matter has seemed like a thin lamina spread over the interior of the enlarged cranium. But there is no proof that absolute destruction of any part was thus occasioned; and it would seem that the very gradual nature of the change gives to the structure time for accommodating itself to it. This, in fact, is to be noticed in all diseases of the Encephalon. The partial or entire absence of the commissures from congenital malformation reducing the Cerebrum (in this respect) at least, to the level of that of the Marsupial Quadruped or of the Bird is by no means an unfrequent cause of deficient intellectual power. In an interesting case recorded by Sir James Paget,† in which the middle portion of the fornix and the whole of the septum lucidum were absent, with a very thin and short corpus callosum, the subject had been a servant-girl, and had during life betrayed a peculiar want of forethought and power of judging of the probable result of things, but her memory was good and she possessed an ordinary amount of knowledge. A similar case has been recorded by Mitchell Henry.‡ The mental deficiencies in this and in most of the few other cases of which the details have been recorded, seem to have been of the same order; and this is exactly what might have been anticipated; since the deprivation of these parts takes away that which is most characteristic of the Cerebrum of Man and of the higher Mammalia; *their* intellectual operations being peculiarly distinguished by that *application of past experience to the prediction of the future*, which constitutes one of the highest efforts of intelligence. A *sudden* lesion, that may be so trifling as to escape observation unless this be very carefully conducted, will occasion very severe symptons; whilst a chronic disease may gradually extend itself, without any external manifestation. It will usually be found that sudden paralysis, of which the seat is in the Brain, results from some slight effusion of blood in the substance or in the neighbourhood of the Corpora striata; whilst, if it follows disorder of long standing, a much greater amount of lesion commonly presents itself. In either case, the paralysis occurs in the opposite side of the *body*, as we should expect from the decussation of

* For abundant evidence on this point see M. Brown-Séquard, "Archives of Scient. and Pract. Med.," vol. i. 1873, p. 255; Kahler and Pick, "Präger Vierteljahrschrift," N. F., 1879, Heft 1 and 2. † "Med.-Chir. Trans.," vol. xxiv. ‡ Op cit., vol. xxxi.

the Pyramids; but it may occur either on the same, or on the opposite side of the *face*—the cause of which has already been explained. The disturbance of the Cerebral functions occasioned by those changes in its nutrition which are commonly included under the general term Inflammation, presents a marked diversity of character according to the part it affects. Thus it is well known that the Delirium of excitement is usually a symptom of inflammation of the cortical substance or of the membranes of the Hemispheres. This is exactly what might be anticipated from the foregoing premises, since this condition is a perversion of the ordinary mental operations, which are dependent upon the instrumentality of the vesicular matter; and it is evidently impossible for the membranes to be affected with inflammation, without the nutrition of this substance being impaired, since it derives all its vessels directly from them. On the other hand, inflammation of the fibrous portion of the Cerebrum is usually attended rather with a state of torpor than with excitement; and with diminished power of the will over the muscles. It is stated by Foville, that in acute cases of Insanity he has usually found the cortical substance intensely red, but without adhesion to the membranes; whilst in chronic cases it is indurated and adherent: but where the insanity has been complicated with paralysis, he has usually found the medullary portion indurated and congested.

526. The numerous and interesting observations which have been made during the last few years on loss of the faculty of language, or rather of intellectual expression,* are of great interest in reference to the Physiology of the Brain. It is commonly associated with Right Hemiplegia, and in a large proportion of the cases examined after death, disease has been found in the posterior part of the third or inferior frontal convolution of the left hemisphere; hence the conclusion has been drawn that the faculty of language has its seat in this particular convolution. Language, however, is co-extensive with thought, and the third left frontal convolution is not the seat of language as a faculty of the mind, but is simply an important link in the nervous mechanism of speech. Dr. Hughlings Jackson† has pointed out that language may be intellectual or emotional, and that when all power of expressing ideas in words is lost, an entire phrase may be uttered under emotion. Intellectual language again, or intellectual expression, he shows to be a department of educated movements in general, and gives reasons for believing that the entire hemisphere is concerned in its evolution. It conflicts with all preconceived notions that the left side of the brain should alone have to do with the expression of ideas in language, but this seems to be clearly demonstrated by Pathology. P. Broca and Dr. Moxon have explained it by supposing that one

side of the brain only is educated, and Gratiolet's observation that the left frontal convolutions are developed before the right, has been adduced in support of this view, which, however, cannot be said to be established. The mechanism of speech and thought may be represented as follows. Impressions derived from sensory surfaces generally (G S, Fig. 248) and from the organs of special sense (O A), are translated in the sensory ganglia of the base of the brain (O T) into sensations. These sensations transmitted upwards to the cortex of the hemispheres here give rise to perceptions, that is, to the intellectual recognition of the external causes of the sensations; by combination again of the different perceptions derived from a given object, an idea or complete intellectual representation of the object is formed, with which is associated a name. The "perceptive centres" (Bastian) in which simple perceptive recognition takes place (P C) are probably situated near the margins of the hemisphere where the convolutions are directly connected by fibres with the central ganglia, while ideas are supposed to be formed in the convolutions remote from the margins, many of which receive no fibres from the central ganglia or crus, but are connected by arcuate fibres with the marginal convolutions and with each other. Up to the present the mechanism described is that concerned in the reception of impressions and the formation and association of ideas. When these ideas are to be expressed in words, the proposition is formulated, and the phrase mentally rehearsed in the higher convolutions, and transmitted for verbal expression to the third left frontal gyrus, the function of which is to provide the appropriate words or motor symbols in which the idea is to be clothed, and call into action through the corpus striatum the motor nerve-nuclei in the medulla which are concerned in articulation and phonation. The third left frontal convolution is thus the first step on the way out for words, and damage here leaves the subject of it able on the one hand to understand what is said, to form ideas, and even to rehearse propositions in his mind, and on the other hand able to execute all the movements required for articulation and phonation, though from the breach in the mechanism for translating ideas into words, he is speechless. This is pure Aphasia, but cases uncomplicated by further damage are rare, while speechlessness of a totally different character is often confounded with Aphasia. The nervous mechanism may, in fact, be injured at different points. Below the third frontal convolution, lesion in the Corpus striatum may cause impairment of articulation, or in the medulla or its nerves, more or less complete loss both of phonation and articulation (*alalia*). Here the speechlessness is simply from motor paralysis, but other forms of speechlessness arise from lesions in the cerebral or mental mechanism. Cases have been met with in which a man could speak and write correctly while unable to read a single word even of what he had himself written, or to name the most familiar object shown to him; the association by which the visual perception called up the name was broken. Let the association between the auditory perception and the name be similarly broken, and we have the explanation of the perplexing cases* in which a patient has lost all comprehension of articulate sounds, and neither understands what is said to him nor what he says, while he responds promptly to signs and appears to be intelligent. These are forms of Amnesia or loss of memory for words, but there are other more common forms of Amnesia in which a patient understands spoken words, but cannot recall them mentally so as to rehearse a phrase or proposition in his mind. Very frequently a degree of Amnesia is associated with Aphasia, the various degrees and combinations of loss of

* See Broadbent, "Med.-Chir. Trans.," 1872–5, to whom the Editor is indebted for aid in drawing up this section, and for the Figure by which it is illustrated.

memory for words and loss of memory how to say words depending upon the region and extent of cortex involved, or upon the severance of fibres connecting together different sets of convolutions. Again, in extensive disease of the Cortex there is no speech because there is no idea; this is dementia or mutism.

527. The general result of pathological investigation is, that the Cerebrum is the instrument of all those *psychical* operations, which we include under the general term *Intellectual*, whilst it also affords, in part at least, the instrumental conditions of *Emotional* states; and that all those muscular movements which result from *voluntary* determinations, or which are directly consequent upon *emotional* excitement, have their origin in its vesicular substance, though the motor impulse is immediately furnished by the Cranio-Spinal apparatus, upon which the Cerebrum plays (§ 524). It does not hence follow, however, that the Cerebrum has such a direct relation to the Mind, that the consciousness is immediately and necessarily affected by changes taking place in its own substance; and, however startling the proposition may at first sight appear, that the organ of the intellectual operations is not itself endowed with consciousness, a careful consideration of the relations of the Cerebrum to the Sensory ganglia will tend to show that there is no *à priori* absurdity in such a notion. For if the connection of the vesicular matter of the Cerebral hemispheres with the Sensorial centres be anatomically the same as that which exists between these centres and the Retina or any other peripheral expansion of vesicular matter in an organ of sense, which we have seen that it is—and if the same kind of change may be excited in the Sensorial centres by an impression from each source, which has been shown to be a matter of common occurrence—it can scarcely be deemed unlikely that the Sensorial centres should be the seat of consciousness, not merely for the impressions transmitted to them by the nerves of the external senses, but also for the impressions brought to them by the 'nerves of the internal senses,' as we may designate (after Reil) the radiating fibres of the Cerebral hemispheres. And there is on the other hand an *à priori* improbability that there should be *two* seats of consciousness, so far removed from one another as the Sensory ganglia and the vesicular surface of the Hemispheres (for to their medullary substance no such attribute can be assigned with the least probability); an idea which is quite at variance with that very simple and familiar class of phenomena, which consists in the *recollections of sensations*. For the remembered sensation is so completely the reproduction of the original, that we can hardly suppose the seat of the two to be different; yet the act of recollection is clearly Intellectual, and therefore Cerebral; consequently, if we admit that the Sensory ganglia are the seat of the original sensation, we can scarcely but admit that they are also the seat of that which is reproduced by the Cerebral act—a view which is fully confirmed by the occurrence of automatic movements as consequences of its recall. And a careful analysis of our own mental operations will often supply evidence of the evolution of results, such as ordinarily proceed from intellectual action, without any consciousness on our own parts of the steps whereby these are attained. Without presuming, then, to affirm positively what cannot be proved, it may be stated as a probable inference from the facts already referred to, that the Sensory ganglia constitute the seat of consciousness, not merely for impressions on the Organs of Sense, but also for changes in the cortical substance of the Cerebrum; so that, until the latter have reacted downwards upon the Sensorium, we have no consciousness either of the formation of ideas, or of any intellectual process of which these may be the subjects.—Ideas, Emotions, Intellectual operations, &c., have of late been frequently designated as 'states

of consciousness;' and this psychological description of them is in full harmony with the physiological account here given of the material conditions under which they respectively occur. For as a Sensation is a state of consciousness excited through the instrumentality of the Sensorium, by a certain change—*e.g.*, in the condition of the Retina—it is not difficult to understand how a change in the condition of the Cerebrum may excite, through the same instrumentality, that state of consciousness which may be termed Ideational,* or that another change may produce the Emotional consciousness, another the Intuitional consciousness, another the Logical consciousness. And although it may be thought at first sight to be a departure from the simplicity of Nature to suppose that the Cerebrum should require another organ to give us a consciousness of its operations, yet we have the knowledge that the Eye does not give us visual consciousness, nor the Ear auditory consciousness, unless they be connected with the Sensory ganglia; and in the end (the Author feels a strong assurance) it will be found much simpler to accept the doctrine of a common centre for *sensational*, and for what may be distinguished as *mental* consciousness, than to regard the two centres as distinct.†

6. *Of Sleep and Somnambulism.*

528. It is a peculiar feature in the physiology of the Cerebral and Sensorial ganglia, that their activity undergoes a periodical suspension more or less complete; the necessity for this suspension arising out of the fact that the exercise of their functions is in itself destructive to their substance, so that, if this be not replaced by nutritive regeneration, they speedily become incapacitated for further use. An ingenious theory of the *cause* of sleep has been advanced by Sommer,‡ founded on the observations of Pettenkofer and Voit already alluded to (§ 287, viii.). Sommer observes that if, as the experiments of Pettenkofer appear to show, oxygen is gradually being stored up during sleep, a period will probably arrive when it exists in such excess as materially to accelerate the metamorphosis of the nervous and other tissues, and as a consequence awakening occurs. On the other hand, during the waking state the stored-up oxygen is gradually eliminated, as shown by the large proportion of carbonic acid given off, until at length, when all the excess has been consumed, exhaustion and general relaxation is experienced, accompanied by the desire for sleep. This view has been expressed at considerable length by Pflüger,§ who suggests that the waking state is maintained by the violent oscillations, almost comparable to small explosions, taking place in the molecules of the cerebral substance, owing to the combination of the intra-molecular oxygen with the carbon of the tissue. These vibrations radiate outwards far and wide along the nerves in all directions. As the oxygen is gradually used up, the explosions become feebler, the activity of all nervous processes less, mental operations are conducted with less energy, the exhausted and quiescent nerves are no longer easily aroused by impressions from without, and sleep results. On Dr. Cappie's‖ theory, the links in the causation of sleep are, first,

* The Author ventures to use this term, the meaning of which requires no explanation, on the authority of Mr. James Mill, who remarks:—"As we say Sensation, we might also say Ideation; it would be a very useful word, and there is no objection to it, except the pedantic habit of decrying a new term. Sensation is the general name for one part of our constitution [or rather, for one state of our consciousness], Ideation for another." ("Analysis of the Human Mind," vol. i. p. 42.)—If the use of the substantive Ideation be admitted, there can be no reasonable objection to the adjective *ideational*.

† An interesting and suggestive paper by Mr. Lockhart Clarke, 'On the Nature of Volition,' will be found in Nos. 7, 8, and 9 of the "Psychological Journal" for 1862.

that there is diminished molecular activity of the cerebral cells, whilst coincidently there is a change in the capillary circulation of the brain, so that less blood is supplied to it, and it consequently occupies less space. But as the brain-case must be constantly full, the veins of the pia mater undergo gradual and proportional distension, and although the absolute quantity of blood and the amount of internal pressure remain unaltered, the direction of the pressure is modified. It is less from within, and more on the surface of the organ, and with altered direction of pressure the continued exercise of function is incompatible. This view is quite in accordance with the interesting researches of Mr. Arthur Durham* on the condition of the circulation in the Brain during sleep, which have shown that the brain is then in an essentially bloodless condition, and that not only the quantity but the rapidity of movement of the blood in the vessels is materially diminished; and this is corroborated by the observations of Dr. J. Hughlings Jackson on the ophthalmoscopic condition of the Retina during sleep,† the optic disc being then whiter, the arteries smaller, the veins somewhat larger, and the neighbouring part of the retina more anæmic, than in the waking state. In ordinary profound Sleep there is a state of complete unconsciousness, so far as *external* phenomena are concerned; no ordinary impressions upon the organs of sense being either felt or perceived; although an extraordinary impression, or even an habitual one upon which the attention has been previously fixed as that at which the slumberer is to awake himself (§ 534), occasions a renewal of activity. It is in this capability of being aroused by external impressions that the chief difference lies between Sleep and the abnormal condition of Coma, whether this arise from the influence of pressure or effusion within the cranium, or be consequent upon the poisoning of the blood by narcotic substances, or follow a previous state of abnormal activity of the brain, such as Delirium. Between these two conditions, however, every gradation may be seen; as in the gradually increasing torpor which results from slow effusion within the cranium, the gradual loss of susceptibility to external impressions which is observed on the application of cold to the nervous centres, as in the interesting experiments of Dr. Richardson and Dr. Weir Mitchell,‡ or after an overdose of a narcotic, as well as in the intensification of ordinary sleep which is consequent upon extreme previous fatigue. But it is a matter of doubt whether the suspension of sensorial consciousness is equally complete as regards *internal* or cerebral changes; for some are of opinion that, even in the most profound sleep, we still dream, although we may not remember our dreams; whilst others (and among these the Author would rank himself) consider that dreaming is a mark of imperfect sleep, and that, in profound ordinary sleep, the Cerebrum, in common with the Sensory ganglia, is in a state of complete functional inactivity. When Dreaming takes place, there is usually a less complete exclusion of sensory impressions, although the perceptive consciousness may be entirely suspended; so that the course of the dream may be influenced by them, although the mind is not conscious of them as such (§ 538). If this be the true account of the case, we may consider that in profound Sleep the functional activity of the Cerebrum and of the Sensory ganglia is alike suspended; but that in Dreaming the Cerebrum is partially active, whilst the Sensorium is in such a condition of receptivity for Cerebral (subjective) impressions that the mind becomes directly conscious of them, though

it only becomes conscious of (objective) impressions made upon the Organs of Sense, after their influence has been transmitted through it to the Cerebrum, and has been, as it were, reflected back by that organ. It is, in fact, by their influence upon the current of *ideas*, and not by their power of exciting *sensations*, that we recognise their operations under such circumstances.

529. The state of sleep is one to which there is beyond doubt a *periodical* tendency; for, when the waking activity has continued during a considerable proportion of the twenty-four hours, a sense of fatigue is usually experienced, which indicates that the brain requires repose; and it is only under some very strong physical or moral stimulus that the mental energy can be maintained through the whole cycle. In fact, unless some decidedly abnormal condition of the Cerebrum be induced by the protraction of its functional activity, Sleep will at last supervene, from the absolute inability of the organ to sustain any further demands upon its energy, even in the midst of opposing influences of the most powerful nature.* That the strongest volitional determination to remain awake is forced to give way to Sleep, when this is required by the exhaustion of nervous power, must be within the experience of every one; and the only way in which the Will can even retard its access, is by determinately fixing the consciousness upon some definite object, and resisting every tendency in the thoughts to wander from this. It does not appear to be of any consequence whether this exhaustion be produced by the active exercise of volition, reflection, emotion, or simple sensation; still we find that the *volitional* direction of the thoughts in a course different from that in which they tend spontaneously to flow, is productive of far more exhaustion than the automatic activity of the mind; whilst, on the other hand, the excess of *automatic* activity, whether as regards the intellectual operations or emotional excitement, tends to prevent sleep. This is particularly the case when the feelings are deeply interested; thus the strong desire to work out a result, or to complete the survey of a subject, is often sufficient to keep up the intellectual activity as long as may be requisite (a state of restlessness indeed being often induced, which prevents the access of sleep for some time longer); so, again, anxiety or distress is a most frequent cause of wakefulness; and it is generally to be observed that the state of *suspense* is more opposed to the access of sleep than the greatest joy or the direst calamity when certainty has been attained.† But although an excess of automatic activity is opposed, so long as it continues, to the access of sleep, yet it cannot be long protracted

* Thus it is on record, that during the heat of the battle of the Nile, some of the overfatigued boys fell asleep upon the deck: and during the last attack upon Rangoon, the Captain of one of the war-steamers most actively engaged, worn-out by the excess of continued mental tension, fell asleep, and remained perfectly unconscious for two hours, within a yard of one of his largest guns, which was being worked energetically during the whole period.—So even the severest bodily pain yields before the imperative demand occasioned by the continued exhaustion of the powers of the sensorial centres; thus Damiens slept upon the rack, during the intervals of his cruel sufferings; the North American Indian at the stake of torture will go to sleep on the least remission of agony, and will slumber until the fire is applied to awaken him; and the Medical Practitioner has frequent illustrations of the same fact.—That the continued demand for muscular activity is not incompatible with the access of sleep, is obvious from what has been already said of the persistence of the automatic movements in that condition; it is well known that, previously to the shortening of the hours of work, factory children frequently fell asleep whilst attending to their machines, although well aware that they would incur severe punishment by doing so.

† Thus it is a common observation, that criminals under sentence of death sleep badly so long as they entertain any hopes of a reprieve; but when once they are satisfied that their death is inevitable, they usually sleep more soundly, and this even on the very last night of their lives.

without occasioning an extreme exhaustion of nervous power, which necessitates a long period of tranquility for its complete restoration. Whilst, however, the necessity for Sleep arises out of the state of the nervous system itself, there are certain external conditions which favour its access; and these, in common parlance, are termed its predisposing causes. Among the most powerful of these, is the *absence* of sensorial impressions; thus, darkness and silence usually promote repose; and the cessation of the sense of muscular effort, which takes place when we assume a position that is sustained without it, is no less conducive to slumber. That sleep ensues when all stimuli to cerebral activity are withdrawn, is remarkably shown by a case recorded by Dr. Strümpell.* In this instance, a girl of sixteen years of age became almost completely anæsthetic, being unable to perceive the most violent stimulation of the skin and mucous membranes, losing the muscular sense, and even the sense of muscular fatigue, and preserving her relation with the outer world by two channels only—the right eye and the left ear. It was found that on applying a bandage to the eye and plugging the ear, she fell in the course of two or three minutes into a deep sleep. She could be awaked from this by the application of the natural stimulus either to the ear or eye, though if allowed to sleep for several hours, waking occurred naturally, apparently from the action of certain internal stimuli. There are cases, however, in which the *continuance* of an accustomed sound is necessary, instead of positive silence, the cessation of the sound being a complete preventive of sleep; thus it happens that persons living in the neighbourhood of the noisiest mills or forges cannot readily sleep elsewhere. Such cases are referable either to the influence of *habit*, which causes the attention of the individual to be more attracted by the suspension of the sound than by its continuance; or to the fact that the *monotonous repetition* of sensorial impressions is often more favourable to sleep than their complete absence. Thus it is within the experience of every one, that the droning voice of a heavy reader on a dull subject is often a most effectual hypnotic; in like manner, the ripple of the calm ocean on the shore, the sound of a distant waterfall, the rustling of foliage, the hum of bees, and similar impressions upon the auditory sense, are usually favourable to sleep; and the muscular and tactile senses may be in like manner affected by an uniform succession of gentle movements, as we see in the mode in which nurses 'hush off' infants, or in the practice of gently rubbing some part of the body which has been successfully employed by many who could not otherwise compose themselves to sleep. The reading of a dull book acts in the same mode through the visual sense; for the eyes wander on from line to line, and from page to page, receiving a series of sensorial impressions which are themselves of a very monotonous kind, and which only tend to keep the attention alive in proportion as they excite interesting ideas.

530. In these and similar cases the influence of external impressions would seem to be exerted in withdrawing the mind from the distinct consciousness of its own operations (the loss of which is the transition state towards that of complete unconsciousness), and in suspending the directing power of the Will. And this is the case, even where the attention is in the first instance *voluntarily* directed to them; as in some of the plans which have been recommended for the induction of sleep, when there exists no spontaneous disposition to it. In other methods, the attention is fixed upon some internal train of thought, which, when once set going, may be carried on automatically; such as counting numbers, or repeating a French, Latin, or Greek verb. In either case, when the sensorial consciousness has been once steadily fixed, the monotony of the

* Pflüger's "Archiv," Band xv. 1877, p. 573.

impression (whether received from the Organs of Sense, or from the Cerebrum) tends to retain it there; so that the Will abandons, as it were, all control over the operations of the mind, and allows it to yield itself up to the soporific influence. This last method is peculiarly effectual when the restlessness is dependent upon some mental agitation; provided that the Will has power to withdraw the thoughts from the exciting subject, and to reduce them to the tranquillizing state of a mere mechanical repetition. The access of Sleep is sometimes quite sudden; the individual passing at once from a state of complete mental activity to one of entire torpor. More generally, however, it is gradual; and various intermediate phases may be detected, some of which bear a close resemblance to the state of Reverie. The same may be said with regard to the transition from the state of Sleep to that of wakeful activity; and this also may be sudden and complete, although it usually consists of a succession of stages—the complete consciousness of the individual's relation to the external world, and the power of directing his thoughts and actions to any subject about which he may be required to exert himself, being the last to return to him. There may be a rapid alteration of these different states; the loss and recovery of the waking consciousness being many times repeated in the course of a few minutes, when the circumstances are such as to prevent the access of profound sleep by the recurrence of sensory impressions; as when a man on horseback, wearied from want of rest, lapses at every moment into a dozing state, from which the loss of the balance of his body as frequently and suddenly arouses him; or when a man going to sleep in a sitting posture, gradually loses the support of the muscles which keep his head erect, his head droops by degrees, and at last falls forward on his chest, and the slight shock thence ensuing partially arouses and restores his voluntary power, which again raises the head. Similar fluctuations occur in the sensory perceptions; and these may be often artificially induced by very simple means. "We find, for example, one condition of sleep so light, that a question asked restores consciousness enough for momentary understanding and reply; and it is an old trick to bring sleepers into this state, by putting the hand into cold water, or produce some other sensation, not so active as to awaken, but sufficient to draw the mind from a more profound to a lighter slumber. This may be often repeated, sleep still going on; but make the sound louder and more sudden, and complete waking at once ensues. The same with other sensations. Let the sleeper be gently touched, and he shows sensibility, if at all, by some slight muscular movement. A ruder touch excites more disturbance and motion, and probably changes the current of dreaming; yet sleep will go on; and it often requires a rough shaking, particularly in young persons, before full wakefulness can be obtained.". . . . "It is certain that the faculties of sensibility and volition are often unequally awakened from sleep. The case may be stated, familiar to many, of a person sleeping in an upright posture, with the head falling over the breast; in whom sensibility is suddenly aroused by some external impression, but who is unable, for a certain time, to raise his head, though the sensation produced by this delay of voluntary action is singularly distressing." These various cases, it is justly remarked by Sir H. Holland,* depending severally on the intensity of sleep, and on the kind and degree of the external exciting causes will be found to explain many of those so-called mesmeric phenomena, which are offered to us under a widely different interpretation. And it may be here remarked, that among those intermediate stages between sleep and waking, which either occur spontaneously, or can be

* See his excellent chapter on 'Sleep,' from which the above extracts are taken, in his "Medical Notes and Reflections," and his "Chapters on Mental Physiology."

induced in numerous individuals by very simple processes, there are several which exhibit peculiarities that are not in themselves in the least degree less remarkable, than are those which are regarded with so much wonder by the uninformed observer, when induced by the asserted mesmeric influence, and paraded as specimens of its power.

531. It is unquestionable that the supervention of sleep may be promoted by the strong previous expectation of it; and this is true, not merely of ordinary sleep, but of the states of artificial Reverie and Somnambulism formerly described. Everyone knows the influence of habit, not only in regard to 'time,' but also as to 'place and circumstance,' in predisposing to Sleep. Thus, the celebrated pedestrian, Captain Barclay, when accomplishing his extraordinary feat of walking 1000 miles in as many consecutive hours, obtained at last such a mastery over himself that he fell asleep the instant he lay down. And the sleep of soldiers, sailors, and others, who are prevented by 'duty' from obtaining regular periods of repose, but are obliged to take their rest at short intervals, may be almost said to come at command; nothing more being necessary to induce it, than the placing the body in an easy position and the closure of the eyes. It is related that the Abbé Faria, who acquired notoriety through his power of inducing somnambulism, was accustomed merely to place his patient in an arm-chair, and then, after telling him to shut his eyes and collect himself, to pronounce in a loud voice and imperative tone the word "dormez," which was usually successful. The Author has had frequent opportunities of satisfying himself, that the greater success which attended the 'hypnotic' mode of inducing somnambulism, in the hands of Mr. Braid, its discoverer, than in that of others, partly lay in the mental condition of his subjects who came to him for the most part under the confident expectation of its production, and were further assured by a man of very determined will, that it *could not* be resisted.* And it is one of the most curious phenomena of the state of induced Reverie, absurdly called 'biological,' that, in many subjects at least, sleep may be induced in a minute or less, by the positive assurance, with which the mind of the individual becomes possessed, that it *will* and *must* supervene.

532. The influence of previous mental states is yet more remarkable in determining the effects produced upon the sleeper by different sensory impressions. The general rule is, that *habitual* impressions of any kind have much less effect in arousing the slumberer, than those of a new or unaccustomed character. An amusing instance of this kind has been related to the Author, which, even if not literally true, serves extremely well as an illustration of what is unquestionably the ordinary fact. A gentleman who had taken his passage on board a ship of war, was aroused on the first morning by the report of the morning gun, which chanced to be fired just above his berth; the shock was so violent as to cause him to jump out of bed. On the second morning, he was again awoke, but this time he merely started and sat up in bed; on the third morning, the report had simply the effect of causing him to open his eyes for a moment, and turn in his bed; on the fourth morning, it ceased to affect him at all; and his slumbers continued to be undisturbed by the report, so long as he remained on board. It often happens that sleep is terminated by the *cessation* of an accustomed sound, especially if this be one whose monotony or continuous repetition had been the original inducement to repose. Thus, a person who has been read or preached to sleep, will awake, if his slumber be

* A very amusing instance in which Sleep, having been previously induced by the ordinary 'mesmeric' and then by the 'hypnotic' processes, was brought on by the simple belief that a new process was being put in practice, will be found in the "Brit. and For. Med. Rev.," vol. xix. p. 477.

not very profound, on the cessation of the voice; and a naval officer, sleeping beneath the measured tread of the watch on deck, will awake if that tread be suspended.—In this latter case the influence of the simple cessation of the impression will be augmented by the circumstance next to be alluded to, which has received too little attention from writers on this subject, but which is of peculiar interest both in a physiological and psychological point of view, and is practically familiar to almost everyone.

533. The awakening power of sensory impressions is greatly modified by our *habitual state of mind* in regard to them. Thus, if we are accustomed to *attend* to these impressions, and our perception of them is thus *increased* in acuteness, we are much more easily aroused by them, than we are by others, which are in themselves much stronger, but which we have been accustomed to disregard. Thus, most sleepers are aroused by the sound of their own names uttered in a low tone, when it requires a much louder sound of a different description to produce any manifestation of consciousness. The same thing is seen in comatose states; a patient being often found capable of being momentarily aroused by shouting his name into his ear, when no other sound produces the least effect.—The following circumstance, communicated to the Author by the late Sir Edward Codrington, is a most apposite illustration of this principle. When a young man, he was serving as signal-lieutenant under Lord Hood, at the time when the French fleet was confined in Toulon harbour; and being desirous of obtaining the favourable notice of his commander, he devoted himself to his duty (that of watching for signals made by the look-out frigates) with the greatest energy and perseverance, often remaining on deck nineteen hours out of the twenty-four, with his attention constantly directed towards this one object. During the few hours which he spent in repose, his sleep was so profound that no noise of an ordinary kind, however loud, would awake him; and it used to be a favourite amusement with his comrades, to try various experiments devised to test the soundness of his sleep. But if the word 'signal' was even whispered in his ear, he was instantly aroused, and fit for immediate duty.—The influence of habitual attention is shown as much in the effect produced by the cessation, as in that of the occurrence, of sensory impressions. Thus, in the case of the naval officer aroused by the suspension of the measured tread of the watch over his head, the knowledge possessed during the waking state, that this suspension is either an act of negligence which requires notice, or indicates some unusual occurrence, doubtless augments the effect which the discontinuance of the sound would of itself produce.

534. It is not requisite, however, that the sound should be one habitually attended to during the hours of watchfulness; for it is sufficient if it be one on which the *attention has been fixed* as that at which the slumberer is to arouse himself. Thus, the medical man, even in his first profound sleep after a fatiguing day's work, is aroused by the first stroke of the clapper of his night-bell; and to those who are accustomed to rise every morning at the sound of an alarum-clock, the frequency and regularity of the occurrence do not diminish, but rather increase, the readiness with which it produces its effects, provided that the warning be promptly obeyed. On this usually depends the efficiency of the awakening sound; if it be regarded as a thing to which there is no occasion to give heed, it very soon ceases to produce any effect, the entire peal not being sufficient to awake the sleeper; whilst, on the other hand, the first stroke is enough to break the repose of him who is impressed with the effectual desire of profiting by the warning. And thus it may happen that, of two persons in the same room, either shall be at once aroused by a sound which

produces no disturbance in the slumbers of the other. To this influence of previous impressions, whether habitual, or but once forcibly made, we are also to refer the spontaneous termination of the state of sleep at particular times, without any sensorial excitement from external impressions. Thus, many persons who are accustomed to rise at a particular hour, wake regularly at that hour, whether they have gone to rest early or late; so that the act of spontaneously awakening is no proof that the desirable amount of repose has been obtained. But what is more remarkable is, that many individuals have the power of determining, at the time of going to rest, the hour at which they shall rise, so as to awake from a profound sleep at the precise time fixed upon. In others, however, the desire to rise at a particular hour only induces a state of restlessness throughout the night, destroying the soundness of the slumbers; the individual awakes many times in the night, with the belief that the hour is past, and very possibly oversleeps it after all, the system being worn out by the need of repose.

535. The *Amount of Sleep* required by man is affected by so many conditions, especially *age*, *temperament*, *habit*, and *previous exhaustion*, that no general rule can be laid down on the subject.—The condition of the *fœtus in utero* may be regarded as one of continual slumber; the apparatus of animal life being completely secluded from all stimuli which could arouse it into activity, whilst the energy of the organic functions is entirely directed to the building-up of the fabric. On its first entrance into the world, the infant continues to pass the greater part of its time in slumber; and this is particularly to be noticed in cases of premature birth, the seven months' child seeming to awake only for the purpose of receiving food, and giving but little heed to external objects, whilst even the eight months' child is considerably less alive to sensory impressions than one born at the full time. The excess of activity of the *constructive* over the *destructive* operations, which characterizes the whole period of infancy, childhood, and adolescence (CHAP. XX.), requires that a larger portion of the diurnal cycle shall be passed in sleep (during which the former may be carried on without hindrance), than is requisite when adult age has been attained, the two sets of changes being then balanced; and the amount of sleep to which the system shows itself disposed, gradually diminishes from three-fourths to one-half, and from one-half to one-third, or even to one-quarter, of the twenty-four hours. It is to be noticed that the sleep of children or young persons is not only longer than that of adults, but is also more profound. On the other hand, as age advances, and the bodily and mental activity of the waking state decreases, a smaller amount of sleep suffices; or, if the slumber be protracted, it is usually less deep and refreshing. It may be noticed, however, that very old persons usually pass a large proportion of their time in sleep, or rather in a sort of heavy doze, especially after meals; as if, in consequence of the want of energy of their nutritive operations, a very long period of repose is necessary to repair the waste which takes place during their short period of activity.—In regard to the influence of *temperament*, it may be remarked that a plethoric habit of body, sustained by full diet, usually predisposes to sleep, provided that the digestive powers be in a vigorous condition; persons of this constitution frequently pass nine or ten hours in slumber, and maintain that they cannot be adequately refreshed by less. On the other hand, thin wiry people, in whom the 'nervous' temperament predominates, usually take comparatively little sleep, notwithstanding the greater activity of their nervous system when they are awake; but their slumber, while it lasts, is generally very deep. Persons of 'lymphatic' temperament, heavy passionless people, who may be said to live very slowly,

are usually great sleepers; but this is rather because, through the dulness of their perceptions, they are less easily kept awake by sensorial or mental excitement, than because they really require a prolonged cessation of activity. As they are half asleep during the waking state, so would it appear that the constructive operations must be far from active while they are asleep, so little do they seem restored by the repose.—The amount of sleep, *cæteris paribus*, required by individuals, is very greatly influenced by *habit;* and, contrary to what we might anticipate, we find that the briefest sleepers have usually been men of the greatest mental activity. Thus Frederick the Great and John Hunter are said to have only required five hours' sleep out of the twenty-four: and General Elliott, celebrated for his defence of Gibraltar, is recorded not to have slept more than four hours out of the twenty-four. It may be doubted whether it would be possible for any one to sustain a life of vigorous exertion upon a smaller allowance than this; and the general fact is, that from six to eight hours of repose, out of every twenty-four, are required to keep the system of an adult in a state of healthful activity. The influence of habit may be brought to bear upon the protraction, as well as on the abbreviation, of the usual period. Thus Quin, the celebrated actor, could slumber for twenty-four hours successively; and Dr. Reid, the metaphysician, could take as much food, and afterwards as much sleep, as were sufficient for two days.—It is needless to dwell upon the obvious fact, that other things being equal, the amount of sleep required by man is proportional to the *amount of mental exertion* put forth during the waking hours; since this is an obvious result of what has been laid down as the cause of the demand for sleep. It may be remarked, however, that we must not measure the *amount* of sleep by its *duration* alone: since its *intensity* is a matter of equal importance. The light slumber which is disturbed by the slightest sounds, cannot be as renovating as the profound sopor of those whom no ordinary noise will awake.

536. There are certain states of the Encephalic centres, in which there is an *entire absence of Sleep;* and this may continue for many days, or even for weeks or months. Insomnia is, for instance, one of the characteristics of acute Mania, and may also exist in various forms of Monomania; it is usually, also, one of the symptoms of incipient meningeal inflammation; and it may constitute a specific disease in itself. In all these cases, however, the preponderance of the *destructive* processes over the *constructive* manifests itself, sooner or later, in the exhaustion of the mental and bodily powers. Thus Mania, when prolonged or frequently recurring, subsides into Dementia; and if it continue for any length of time, is sure to be followed by a great sense of wretchedness and prostration frequently accompanied by continual restlessness. Such effects, too, in a less aggravated degree, result from habitual *deficiency* of sleep; whether this be due to emotional excitement which keeps repose at bay, or to a voluntary determination to keep the intellect in activity. This is a very common occurrence among industrious students, who, with a laudable desire for distinction, allow themselves less than the needed quantum of repose. Headache, tension, heat, throbbing, and various other unpleasant sensations in the head, give warning that the brain is being overtasked; and if this warning be not taken, sleep, which it was at first difficult to resist, becomes even more difficult to obtain; a state of general restlessness and feverish excitement is induced; and if, in spite of this, the effort be continued, serious consequences in the form of cerebral inflammation, apoplexy, paralysis, fever, insanity, or loss of mental power, more or less complete, are nearly certain to be induced. Some individuals can sustain such an effort much longer than others, but it is a great mistake to suppose that they are not

equally injured by it; in fact, being possessed with the belief that they are not suffering from the exertion, they frequently protract it, until a sudden and complete prostration gives a fearful demonstration of the cumulative effects of the injurious course in which they have been persevering. Those, consequently, who are earlier forced to give way, are frequently capable of accomplishing more in the end.—In regard to the degree of *protraction* of sleep which is consistent with a healthy state of the system in other respects, it is difficult to speak with certainty. Of the numerous well-authenticated instances on record,* in which sleep has been continuously prolonged for many days or even weeks, it is enough here to state that they cannot be regarded as examples of natural sleep; the state of such persons being more closely allied to hysteric coma. An unusual tendency to ordinary sleep generally indicates a congested state of the brain, tending to apoplexy; and it has been stated that apoplexy has been actually induced by the experimental attempt to ascertain how large a proportion of the diurnal cycle might be spent in sleep.—Thus, on either side, inattention to the dictates of Nature, in respect to the amount of sleep required for the renovation of the system, becomes a source of disease, and should therefore be carefully avoided.

537. *Dreaming.*—We have hitherto spoken of Sleep in its most complete or profound form; that is, the state of complete unconsciousness. But with the absence of consciousness of external things, there may be a state of mental activity of which we are more or less distinctly cognizant at the time, and of which our subsequent remembrance in the waking state varies greatly in completeness. The chief peculiarity of this state of *dreaming* appears to be, that there is an entire suspension of volitional control over the current of thought, which flows on automatically, sometimes in a uniform coherent order, but more commonly in a strangely incongruous sequence. The former is most likely to occur when the mind simply takes up the train of thought on which it had been engaged during the waking hours, not long previously; and it may even happen that, in consequence of the freedom from distraction resulting from the suspension of external influences, the reasoning processes may thus be carried on during sleep with unusual vigour and success, and the Imagination may develop new and harmonious forms of beauty.† The more general fact is, however, that there is an entire want of any ostensible coherence between the ideas which successively present themselves to the consciousness; and yet we are completely unaware of the incongruousness of the combinations which are thus formed. It has been well remarked that "nothing surprises us in dreams." All probabilities of "time, place, and circumstance" are violated; the dead pass before us as if alive and well; even the sages of antiquity hold personal converse with us; our friends at the Antipodes are brought upon the scene, or we ourselves are conveyed thither, without the least perception of the intervening distance; and occurrences, such as in our waking state would excite the strongest emotions, may be contemplated without the slightest feeling of a painful or pleasurable nature.

* Such, for example, as that of Samuel Chilton ("Phil. Trans.," 1694), and that of Mary Lyall ("Trans. of Roy. Soc. of Edinb.," 1818).

† Thus, Condorcet saw in his dreams the final steps of a difficult calculation which had puzzled him during the day; and Condillac tells us that, when engaged in his "Cours d'Etude," he frequently developed and finished a subject in his dreams, which he had broken off before retiring to rest. Coleridge relates of himself that his fragment "Kubla Khan" was composed during sleep, which had come upon him whilst reading the passage in Purchas's "Pilgrimage," on which the poetical description was founded, and was written down immediately on awaking, "the images rising up before him as things, with a parallel production of the corresponding expressions, without any sensation or consciousness of effort."

Facts and events long since forgotten in the waking state, and remaining only as latent impressions on the Cerebrum, present themselves to the mind of the dreamer; and many instances have occurred in which the subsequent retention of the knowledge thus re-acquired has led to most important results.* But one of the most remarkable of all the peculiarities in the state of dreaming, is the *rapidity* with which trains of thought pass through the mind; for a dream in which a long series of events has seemed to occur, and a multitude of images has been successively raised up, has been often certainly known to have occupied only a few minutes, or even seconds, although whole years may seem to the dreamer to have elapsed. There would not appear, in truth, to be any limit to the amount of thought which may thus pass through the mind of the dreamer, in an interval so brief as to be scarcely capable of measurement; as is obvious from the fact, that a dream involving a long succession of supposed events, has often distinctly originated in a sound which has also awaked the sleeper, so that the whole must have passed during the almost inappreciable period of transition between the previous state of sleep and the full waking consciousness.† Hence it has been argued by some, that *all* our dreams really take place in the momentary passage between the states of sleeping and waking; but such an idea is not consistent with the fact, that the course of a dream may often be traced by observing the successive changes of expression in the countenance of the dreamer. It seems, however, that those dreams are most distinctly remembered in the waking state which have passed through the mind during the transitional phase just alluded to; whilst those which occur in a state allied to Somnambulism are more completely isolated from the ordinary consciousness.—There is a phase of the dreaming state which is worthy of notice as marking another gradation between this and the vigilant state; that, namely, in which the dreamer has a consciousness that he is dreaming, being aware of the unreality of the images which present themselves before his mind. He may even make a voluntary and successful effort to prolong them if agreeable, or to dissipate them if unpleasing; thus evincing the possession of a certain degree of that directing power, the entire want of which is the characteristic of the true state of Dreaming.

538. But the sensibility to external impressions may not be entirely suspended in Dreaming; and it is curious that even where sensations are not recognized by the mind of the dreamer as proceeding from external objects, they may affect the course of its own thoughts; so that the character of the dreams may be in some degree predetermined by such an arrangement of sensory impressions as is likely to modify them. This is especially the case in regard to the dreamy state induced by certain narcotics, such as the Hachisch (a preparation of *Cannabis Indica*), employed for this purpose in the East; for the emotional condition of the individual under its influence is entirely under the control of external impressions; so that those who give themselves up to the intoxication of the *fantasia*, take care to withdraw themselves from everything that could give their delirium a tendency to melancholy, or excite in them anything else than feelings of pleasurable enjoyment.‡

* See a number of such cases in Dr. Abercrombie's "Inquiries concerning the Intellectual Powers."

† The only phase of the waking state, in which any such intensely rapid succession of thoughts presents itself, is that which is now well attested as a frequent occurrence, under circumstances in which there is imminent danger of death, especially by drowning; the whole previous life of the individual seeming to be presented instantaneously to his view, with its every important incident vividly impressed on his consciousness, just as if all were combined in a picture, the whole of which could be taken in at a glance.

‡ See the Author's article, "Sleep," in the "Cyclop. of Anat. and Phys.", vol. iv. pp. 688–690; and Moreau, "Du Hachisch et de l'Aliénation Mentale, Etudes Psychologiques," p. 67.

Moreover, there are certain forms of ordinary Dreaming in which the whole succession of thought and feeling (which is made manifest by the words occasionally uttered, or by the play of countenance, or by the more active movements of the dreamer) may be governed by external suggestion; as, for example, in the well-known case of the officer who amused his friends by acting his dreams during the expedition to Louisburgh, the course of these dreams being capable of direction by whispering into the sleeper's ear, especially if this was done by a friend with whose voice he was familiar.* Such forms of Dreaming constitute a transition to the state of Somnambulism.

539. *Somnambulism.*—The phenomena of Somnambulism are so various, that it is difficult to give any general definition that shall include the whole; but it is a condition which is common to all forms of this state, that the controlling power of the Will over the current of thought is entirely suspended, and that all the actions are directly prompted by the ideas which possess the mind; and the differences chiefly arise out of the mode in which the succession of ideas is directed, this being in some cases a coherent sequence through the whole of which some one dominant impression may be traced, whilst in other instances it is more or less completely determinable by external suggestions. These two forms are thus parallel to the states of spontaneous Abstraction and artificial Reverie (Electro-Biology) respectively; but differ from them both in this essential feature—that they occur in a state of consciousness so far distinct from the ordinary waking condition, as not to be connected with it by the ordinary link of Memory; and that although the course of thought in Somnambulism usually manifests the directing influence of previous habits, and the knowledge of persons and things possessed during the waking state may be readily brought before the mind, yet nothing which occurs during the state of Somnambulism is ever retraced spontaneously, or can be brought back by an act of recollection. Impressions upon the nervous system, however, are sometimes left by strong emotional excitement, which give rise to subsequent feelings of discomfort, of whose origin the individual is entirely unconscious.† —In the first of the phases just referred to, a train of reasoning is often carried out with remarkable clearness and correctness, and its results expressed in appropriate language, or otherwise acted on. Thus, a mathematician may work out a difficult problem, an orator may make a speech appropriate to the occasion on which he supposes himself to be called up, or an author may compose and commit to writing poetry or prose upon the subject which occupies his thoughts. But it is a frequent defect of the intellectual operations carried on in this condition, that through the complete absorption of the attention by one set of considerations, no account is taken of others which ought to modify the conclusion; and this, although it may be palpably inconsistent with the teachings of ordinary experience, is not felt to be so, unless the latter should happen to present themselves unbidden to the thoughts.

540. The second of the phases above-mentioned, which is especially seen in the *artificial* Somnambulism induced by the (so-called) *Mesmeric* process, or by the fixed gaze at a near object (as practised by Mr. Braid under the name of *Hypnotism*), is essentially the same as that of the "biological" condition, save in the different relation which they respectively bear to the waking state; for there is the same readiness to receive new impressions through the senses (the visual

* This case is detailed by Dr. Abercrombie ("Inquiries concerning the Intellectual Powers," 5th ed., p. 277), on the authority of Dr. Gregory, to whom it was related by a gentleman who witnessed it. A case of a very similar nature, the subject of which was a medical student at Edinburgh, is related in Smellie's "Philosophy of Natural History."

† See a very curious example of this kind, which fell under the Author's own observation, narrated in the article "Sleep," in the "Cyclop. of Anat. and Phys.," vol. iv. p. 693.

sense, however, being generally in abeyance), and the same want of persistence in any one train of ideas, the direction of the thoughts being entirely determined by the suggestions which are introduced from without. In either of these extreme forms of Somnambulism, and in the numerous intermediate phases which connect the two, the consciousness seems entirely given up to the one impression which is operating upon it at the time; so that whilst the attention is exclusively directed upon any object, whether actually perceived through the senses, or brought suggestively before the mind by previous ideas, nothing else is felt. Thus there may be complete insensibility to bodily pain, the somnambulist's whole attention being given to what is passing in his mind; yet in an instant, by directing the attention to the organs of sense, the anæsthesia may be replaced by ordinary sensibility; or, by the fixation of the attention on any one class of sensations, these shall be perceived with most extraordinary acuteness, whilst there may be a state of complete insensibility as regards the rest.—Thus, the Author has witnessed a case in which such an exaltation of the sense of Smell was manifested, that the subject of it discovered without difficulty the owner of a glove placed in his hand, in an assembly of fifty or sixty persons; and in the same case, as in many others, there was a similar exaltation of the sense of Temperature. The exaltation of the Muscular Sense, by which various actions that ordinarily require the guidance of vision, are directed independently of it, is a phenomenon common to the "mesmeric" with various other forms of artificial as well as of natural Somnambulism. The Author has repeatedly seen Mr. Braid's "hypnotized" subjects write with the most perfect regularity, when an opaque screen was interposed between their eyes and the paper, the lines being equidistant and parallel; and it is not uncommon for the writer to carry back his pen or pencil to dot an *i* or cross a *t*, or make some other correction in a letter or word. Mr. Braid had one patient who would thus go back and correct with accuracy the writing on a whole page of note-paper; but if the paper was moved from the position it had previously occupied on the table, all the corrections were on the *wrong* points of the paper as regarded the *actual* place of the writing, though on the *right* points as regarded its *previous* place; sometimes, however, he would take a fresh departure, by feeling for the upper left-hand corner of the paper, and all his corrections were then made in their right positions, notwithstanding the displacement of the paper.—So, again, when the attention of the somnambulist is fixed upon a certain train of thought, whatever may be spoken in harmony with this is heard and appreciated; but what has no relation to it, or is in discordance with it, is entirely disregarded.*

541. It is among the most curious of the numerous facts which Mr. Braid's investigations upon artificial Somnambulism have brought to light, that the suggestions derived from the "muscular sense" have a peculiar potency in determining the current of thought. For if the face, body or limbs, be brought into an attitude that is expressive of any particular emotion, or that corresponds with that in which it would be placed for the performance of any voluntary action, the corresponding mental state—that is, either an Emotional condition affecting the general direction of the thoughts, or the Idea of a particular action—is called up in respondence to it. Thus, if the hand be placed upon the vertex, the Somnambulist will frequently, of his own accord, draw his body up to its fullest height, and throw his head slightly back; his countenance then assumes an expression of the most lofty pride, and the whole train of thought is obviously under the domination of this feeling; as is manifested by the replies which the individual makes to interrogatories, and by the

* For a further discussion of this subject see the Author's "Mental Physiology and Nature."

tone and manner in which these are delivered. Where the first action does not of itself call forth the rest, it is sufficient to straighten the legs and spine, and to throw the head somewhat back, to arouse the emotion, with its corresponding manifestation, in its full intensity. If, during the most complete domination of this emotion, the head be bent forwards and the body and limbs be gently flexed, the most profound humility then takes place. So, again, if the angles of the mouth be gently separated from one another, as in laughter, a hilarious disposition is immediately generated; and this may be made to give place to moroseness, by drawing the eyebrows towards each other and downwards upon the nose, as in frowning.* So, again, if the hand be raised above the head, and the fingers be flexed upon the palm, the idea of climbing, swinging, or pulling at a rope is called up in such as have been used to such kinds of exertion; if, on the other hand, the fingers be flexed when the arm is hanging down at the side, the idea suggested is that of lifting a weight; and if the same flexure be made when the arm is advanced forwards in the position of striking a blow, the idea of fighting is at once aroused, and the Somnambulist is very apt to put it into immediate execution.†

CHAPTER XIV.

OF THE ORGANS OF THE SENSES, AND THEIR FUNCTIONS.

1. *Of Sensibility in General.*

542. We have seen that the conscious Mind is affected by impressions made upon the corporeal organism—or, in other words, that Sensation is produced—through the instrumentality of a certain part of the Encephalon termed the *Sensorium*, which is the general centre of the nerves both of "special" and of "common" sensibility: the former connect it with the special Organs of Sense, the latter with the body generally, to the several parts of which they are by no means uniformly distributed, some tissues being altogether destitute of them. Those parts of the body which are endowed with sensory fibres, and impressions on which, therefore, give rise to sensation, are ordinarily spoken of as *sensitive;* and different parts are said to be sensitive in different degrees, according to the strength of the sensation produced by a corresponding impression on each. In accordance with the general fact of the dependence of all Nervous action on the continuance of the Circulation of the blood, it is found that the sensory nerves are distributed pretty much in the same proportion as the blood-vessels: that is to say, in the non-vascular tissues—such as the epidermis, hair, nails, cartilage, and bony substance of the teeth—no nerves

* The Author has not only repeatedly witnessed all these effects, as produced by Mr. Braid upon "hypnotized" subjects, of whom several had never been previously in that condition, and had no idea whatever of what was expected from them; but he has been assured by a most intelligent medical friend, who has paid special attention to the psychological part of this inquiry, that having subjected himself to Mr. Braid's practice, and having been only partially thrown into the "hypnotic" state, he distinctly remembers everything that was done, and can retrace the uncontrollable effect upon his emotional state, which was produced by this management of his muscular apparatus.

† On one occasion on which the Author witnessed this result, a violent blow was struck, which chanced to alight upon a second somnambulist within reach; *his* combativeness being thereby excited, the two closed, and began to belabour one another with such energy, that they were with difficulty separated. Although their passions were at the moment so strongly excited, that even when separated they continued to utter furious denunciations against each other, yet a little discreet manipulation of their muscles soon calmed them and restored them to perfect good-humour.

exist, and there is an entire absence of sensibility; and in those whose vascularity is trifling, as in the case with bones, tendons, ligaments, fibrous membranes, and other parts whose functions are simply mechanical, and even with serous and areolar membranes, there are few nerves, and the sensibility is dull. Many of these textures are acutely sensible, however, under certain circumstances; thus, although tendons and ligaments may be wounded, burned, &c., without much consciousness of the injury being aroused, they cannot be stretched without the production of considerable pain; and the fibrous, serous, and areolar tissues, when their vascularity is increased by inflammation, also become extremely susceptible of painful impressions. All very vascular parts, however, do not possess acute sensibility; the muscles, for instance, are furnished with a large supply of blood, to enable them to perform their peculiar function; but they are not sensitive in by any means the same proportion. Even the substance of the brain, and of the nerves of special sensation, appears to be destitute of this endowment; and the same may be said of the mucous membranes lining the interior of the several viscera, which, in the ordinary condition, are much less sensitive than the membranes that cover those viscera, although so plentifully supplied with blood for their especial purposes. The most sensitive of all parts of the body is the Skin, in which the sensory nerves spread themselves out into a minute network; and even of this tissue, the sensibility differs greatly in different parts (§ 548).—The organs of *Special* Sensation become, by the peculiar character of the nerves with which they are supplied, the recipients of impressions of a particular kind: thus, the Eye is sensible to light, the Ear to sound, &c.; and whatever amount of *ordinary* sensibility they possess, is dependent upon other sensory nerves. The eye, for example, contrary to the usual notions, is a very insensible part of the body, unless affected with inflammation; for though the mucous membrane which covers its surface, and which is prolonged from the skin, is acutely sensible to tactile impressions, the interior, with the exception of the Iris, is by no means so, as is well known to those who have operated much on this organ. And the common sensory nerves which supply certain parts of the body, are adapted to receive and convey to the mind impressions of particular kinds, with much greater readiness than they communicate those of a different description; thus the sensibility to tickling is much greater on some parts of the surface than on others; and this kind of excitement, applied to the genitals or to the nipple, produces sensations of a most peculiar order.

543. An active Capillary Circulation being essential to the sensibility of every part supplied with nerves, any cause which retards this deadens the sensibility, as is well seen with regard to Cold; and, on the other hand, an increase in its activity produces a corresponding increase in the sensibility, as is peculiarly evident in the "active congestion" which usually precedes and accompanies Inflammation. A diminution or increase of sensibility to external impressions may arise, however, not only from an abnormal state of the circulation in the organ or part itself, but from the similar conditions affecting that part of the Sensorium in which the impressions are received. Thus in those various conditions of the Encephalon, in which either a stagnation of the circulation, or an abnormal state of the blood (such as that produced by anæsthetic agents), occasions a diminished functional activity in the Sensorial centres, this is marked by obtuseness to sensory impressions; on the other hand, in active congestion of the brain, the most ordinary external impressions produce sensations of an unbearable violence; and in that peculiar condition of the nervous system known under the name of Hysteria, the patients often manifest the same hyperæsthesia, even when the circulation is in a feeble,

rather than in an excited state.* It is remarkable that the sensibility of the mucous membranes lining the internal organs is less exalted by the state of inflammation than is that of most other parts; and in this arrangement we may trace a wise and beneficent provision; since, were it otherwise, the functions necessary to life could not be performed without extreme distress, whenever a very moderate amount of disorder might exist in the viscera. If a joint is inflamed we can give it rest; but to the actions of the alimentary canal we can give little voluntary respite.

544. It is through the medium of Sensation that we acquire a knowledge of the material Universe around us, by the psychical operations which its changes excite in ourselves. The various kinds or modes of Sensation *suggest* to us various ideas regarding the properties of matter; and these properties are known to us, only through the changes which they produce in the several organs. It is well known that instances occur, in which, from some imperfection of the organization, there is an incapacity for distinguishing colours or musical tones, whilst there is no want of sensibility to light or sound; and that some persons are naturally endowed with a much greater range of the sensory faculties than that possessed by others. Hence it does not seem at all improbable, that there are properties of matter of which none of *our* senses can take immediate cognizance; and which other beings might be formed to perceive, in the same manner as *we* are sensible to light, sound, &c. Thus, many animals are affected by atmospheric changes in such a manner that their actions are regarded by Man as indications of the probable state of the weather; and the same is the case in a less degree with some of our own species, who are peculiarly susceptible of the like influences.—Now the most universal of all the qualities or properties of Matter, on which, in fact, our notion of it is chiefly founded, is its occupation of space, producing a more or less complete *resistance* to displacement; and this quality is that through which alone any knowledge of the external world can be obtained by a large proportion of the lower Animals; *contact* between their own surface and some material body being required to produce sensation. We shall presently see, however, that the idea of the *shape* of a body which we form from the touch, results from a very complex process, such as animals of the lower grades can scarcely be supposed to exercise. There can be little doubt that, next to resistance sensibility to *temperature* is the most universally diffused through the Animal kingdom; and probably the consciousness of *luminosity* is the next in the extent of its diffusion.† It is probable that the sense of *taste* (which has a close affinity to that of touch) exists very low down in the animal scale, being obviously of great importance in the selection of food; but the Anatomist has no means of ascertaining where this refinement exists, and where it does not; since the organs of taste and touch are very similar. The sense of *hearing* does not seem to be distinctly present among Invertebrate animals, except in such as approach most nearly to the Vertebrata; it is not improbable, however, that sonorous vibrations may produce an effect upon the system of those animals which do not receive them as *sound*. The

* The influence of toxic agents introduced into the blood, in producing Anæsthesia and Hyperæsthesia, constitutes a very wide field of inquiry, the investigation of which has been ably commenced by Dr. Anstie, in his interesting work on Stimulants and Narcotics (London, 1864). It is remarkable that *Lead* and *Alcohol* should be capable of inducing either of these states.

† There is good reason to believe, from observation of their habits, that many animals are susceptible of the influence, and are directed by the guidance, of *light*, whose organs are not adapted to receive true visual impressions, or to form optical images; and such would seem to be the function of the red spots, frequently seen on prominent parts of the lower Arthropoda and Mollusca, and even of some Echinodermata. Wherever these are of sufficient size to allow their structure to be examined, they are found to be largely supplied with nerves, but to be destitute of the peculiar organization which alone constitutes a true *eye*.

sense of *smell*, which is concerned with one of the least general properties of matter, appears to be the least widely diffused among the whole; being only possessed in any high degree by Vertebrate animals, and being but feebly present in a large proportion of these.

545. Besides the various kinds of sensibility which have been just enumerated, there are others which are ordinarily associated together, along with the sense of material resistance (and its several modifications), and the sense of temperature, under the head of Common Sensation; but several of them, especially those which originate in the body itself, can scarcely be regarded in this light. Such are the feelings of hunger and thirst; that of nausea; that of distress resulting from suspended aeration of the blood; that of "sinking at the stomach," as it is vulgarly but expressively described, which results from strong mental emotion; the sexual sense, and perhaps some others.—Now, in regard to all these, it is impossible in the present state of our knowledge to say, whether their peculiarity results from the particular constitution of the nerves that receive and convey them, or only from a modification of the impressing causes, from the particular endowments of their ganglionic centres, and from the mode in which they operate. Thus we have no evidence whether the nervous fibrils which convey from the lungs the sense of distress resulting from deficient aeration, are of the same or of a different character from those which convey from the surface of the air-passages the sense of the contact of a foreign body. But as we know that all the trunks along which these peculiar impressions travel, do minister to ordinary sensation, whilst the nerves of truly "special" sensation are not sensible to tactile impressions, it is evident that the probability seems in favour of the identity of the fibres which minister to these sensations with those of the usual sensory character. We shall see that with regard to the sense of Temperature there is strong evidence that its peculiarity partly depends on the speciality of the apparatus by which impressions are received at the peripheral extremities of the tactile nerves, and partly upon some peculiarity in the transmitting fibres.

546. There are certain external agencies which can excite changes in the Sensorium through several different channels; the sensation being in each case characteristic of the particular nerve on which the impression is made. Thus pressure, which produces through the nerves of common sensation the feeling of resistance, is well known to occasion, when exerted on the eye, the sensation of light and colours; and, when made with some violence on the ear, to produce "tinnitus aurium." It is not so easy to excite sensations of taste and smell by mechanical irritation; and yet, as was shown by Dr. Baly,* this may readily be accomplished in regard to the former. The sense of nausea may be easily produced, as is familiarly known, by mechanical irritation of the fauces. Electricity still more completely possesses the power of affecting all the sensory nerves with the changes which are peculiar to them; for, by proper management, an individual may be made conscious at the same time of flashes of light, of distinct sounds, of phosphoric odour, of a peculiar taste, and of pricking sensations, all excited by the same cause, the effects of which are modified by the respective peculiarities of the instruments through which it operates.—But although there are some stimuli which can produce sensory impressions on all the nerves of sensation, it will be found that those to which any one organ is *peculiarly* fitted to respond, produce little or no effect on the rest. Thus the ear cannot distinguish the slightest difference between a luminous and a dark object. A tuning-fork which, when laid upon the ear whilst vibrating, produces a distinct musical tone, excites no other sensation when placed upon the eye than a slight jarring feeling. The most delicate

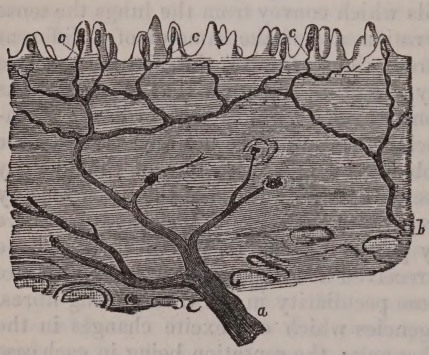
* Translation of Müller's "Elements of Physiology," p. 1062, *note*.

touch cannot distinguish a substance which is sweet to the taste from one which is bitter; nor can the taste (if the communication between the mouth and the nose be cut off) perceive anything peculiar in the most strongly odoriferous bodies.—It may hence be inferred that no nerve of *special* sensation can, by any possibility, take on the function of another.*

2. *Sense of Touch.*

547. By the sense of Touch, as commonly understood, is meant that modification of the common sensibility of the body, of which the Cutaneous surface is the special seat, and by means of which sensations of pressure and temperature are perceived. The Skin is peculiarly adapted for this purpose, not merely by the large amount of sensory nervous fibres which are distributed in its substance, but also by its possession of a papillary apparatus in which these nerves for the most part terminate, or rather commence. The *papillæ* are little elevations of the surface of the cutis, usually simply-conical or clavate in form (Fig. 249), but sometimes presenting several summits. They are divisible into three kinds: first, those which are exclusively vascular, and which constitute the immense majority; secondly, those which are both vascular and nervous; and thirdly, those which are exclusively nervous and are extremely limited in number. On the head, neck, trunk, and greater part of the limbs, there are on the average about 100 papillæ to the square millimeter, and as the body presents a surface of about 15,000 square centimeters, the total number of papillæ is about 150 millions.† On the palmar surface of the hand they are arranged in rows, and are there much less numerous (about 36 being present in each square millimeter). The papillæ are particularly numerous, though without any definite arrangement, on the red surface of the lips, on the penis of the male, on the labia minora and clitoris of the female, and on the nipples of both sexes. Their size is in inverse relation to their number. The nerves of the skin form a plexus near the surface of the corium just beneath the epithelium, and from this plexus fine fibrils come off, which entering the rete Malpighii ascend towards the *stratum corneum*, communicating with each other in the rete Malpighii, to form what Klein regards as a terminal network.‡ Mojsisovics has, however, observed in the pig free club-shaped extremities between the cells of the Malpighian layer. Each sensory papilla receives one or more nerve-fibres from the plexus

Fig. 249.



Vertical Section of the *Skin* of the palmar surface of the fore-finger, showing the branches of cutaneous nerves, *a*, *b*, inosculating to form a terminal plexus, of which the ultimate ramifications pass into the cutaneous papillæ, *c*, *c*, *c*.

* It does not, however, seem a thing altogether incredible, that impressions powerfully arousing one sense may consentaneously excite another sense, and in evidence of this Nussbaumer, "Monatsschrift f. Ohrenheilkunde," March, 1873, records the fact, that both he and his brother can perceive certain colours when the auditory nerve is powerfully excited by certain sounds. In one brother "A" on the piano produces the subjective impression of dark Prussian blue, in the other brother it produces dark yellow. Some of the colours, though differing in the two brothers, are not produced by any sound.

† Sappey, "Anatomie Descriptive," 1872, t. iii. p. 535.

‡ "Centralblatt f. d. Med. Wiss.," 1877, p. 289.

which is formed by the inosculation of the ramifications of the cutaneous nerves (Fig. 249); and these nerve-fibres seem to terminate (at least in the papillæ of the palm of the hand and of the lips, and in the simple papillæ of the tongue) in a peculiar "axile body," which occupies the principal part of the interior of the papilla (Fig. 250).* The *tactile corpuscles* are specially modified terminations of one or more medullated nerve fibres. According to Izquierdo† they consist of a homogeneous dark external layer, surrounding an internal and more transparent mass of protoplasm. The nerves run without division sometimes only as far as the lower pole, sometimes as far as the middle, and sometimes even to the extremity of the corpuscle, frequently winding around it once or twice, and constricting it at these points. The sheath of Schwann then becomes continuous with the outer layer of the corpuscle, whilst the axis-cylinder penetrates and fuses with the central mass of protoplasm. The outer surface of the corpuscles presents numerous transverse cells (Fig. 250 B), the nuclei of which are oblong. After section of the uterus the tactile papillæ undergo fatty degeneration. A very simple form of the axile bodies has been described by Krause as occassionally occuring in the conjunctiva, lips, and soft palate, in the tongue, and in the glans penis and glans clitoridis.‡

‡ Dr. Beale appears to doubt the termination in any instance of sensory nerves by free

Here the nerve forms a "terminal button or knob," consisting of a delicate sheath dotted with nuclei and filled with granular plasma, into which the axis cylinder of the nerve enters terminating by a simple blunt extremity. In the Pacinian bodies, the number of which in Man is estimated by Rauber to be 2142,* a more complex structure is met with than in either of those just mentioned, the chief difference being, that instead of a single sheath there are many investing capsules; a space being, however, always left between the innermost one and the extremity of the nerve, in which a fluid or semi-fluid substance is contained.

548. Every sensory nerve appears to contain afferent fibres that minister to at least three kinds of sensations, namely, those which conduct tactile impressions, those which conduct impressions of pain, and lastly, those which conduct sensations of temperature, and it is not improbable that each has its own peculiar central and peripheral terminal organs. As the "corpuscula tactûs" and "Pacinian bodies" are only to be found in the papillæ of those parts which are distinguished for acuteness of tactile sensibility, we cannot regard them as *essential* to the exercise of the sense of touch; their function, either being to *intensify* tactile impressions, where delicacy of touch is peculiarly required,† or perhaps to supply information in regard to variations in the strength of certain stimuli, as those of temperature or pressure. The relative sensibility of different parts of the Skin may be in some degree judged of by the results of the observations of Prof. E. H. Weber;‡ whose mode of ascertaining it was to touch the surface with the legs of a pair of compasses, the points of which were guarded with pieces of cork; then, (the eyes being closed) the legs were approximated, until they were brought within the smallest distance at which they could be felt to be distinct from one another, which has been termed by Dr. Graves "the limit of confusion." —The following are some of the measurements taken:—

Point of tongue	½ of a line.	Mucous membrane of gums	9 lines.
Palmar surface of third phalanx	1 line.	Lower part of forehead	10 „
Red surface of lips	2 lines.	Lower part of occiput	12 „
Palmar surface of second phalanx	2 lines.	Back of hand	14 „
Palmar surface of metacarpus	3 „	Vertex	15 „
Tip of the nose	3 „	Skin over patella	16 „
Dorsum and edge of tongue	4 „	——— sacrum	18 „
Part of lips covered by skin	4 „	——— acromion	18 „
Palm of hand	5 „	Dorsum of foot	18 „
Skin of cheek	5 „	Skin over sternum	20 „
Extremity of great toe	5 „	Skin beneath occiput	24 „
Hard palate	6 „	Skin over spine, on back	30 „
Dorsum of hand	8 „	Middle of the thigh	30 „

extremities; for he has everywhere obtained demonstrative evidence of a network, the fibres being often of extraordinary tenuity. He believes that in the papillæ of the Skin, and even in the Pacinian bodies, after becoming connected with nuclei or corpuscles the nerve-fibres turn or loop back to the cell from whence they originate.

* "Untersuch.", München, 1867.

† In proof of which, various ingenious experiments have been made by Krause (see "Zeitschrift für Rat. Med.," xvii. p. 278). He explains their presence in the mesentery of the Cat as connected with the mechanism and arrangement of the viscera required for the act of springing.

‡ For similar experiments performed by Dr. Ballard, see "Lancet," 1862, vol. i. p. 303. Dr. Ballard found that in the hand the tip of the index finger was the most, the dorsal surface of the base of the fifth metacarpal bone the least, sensitive part; the limit of confusion in the former being 0·35 of a line, in the latter 5 lines.

It is curious that the distance between the legs of the compasses, as well as the rapidity of their motion when they were lightly drawn over the skin, seemed to be greater (although really less), when it was felt by the more sensitive parts, than when it was estimated by parts of less distinct sensibility. With the extremities of the fingers and the point of the tongue, the distance could be distinguished more easily in the longitudinal direction; on the dorsum of the tongue, the face, neck, and extremities, the distance could be estimated best when the points were placed transversely. As a general fact, it seems that the more numerous are the tactile nerves distributed to any part, the more acute is the sensibility, and the sense can be greatly improved by exercise, the improvement taking place simultaneously on both sides, though only one side may be practised or educated.* Speaking generally also the sensibility of the trunk is greater on the median line, both before and behind, and less at the sides. Differences in the temperature and weight of bodies, were, according to Prof. Weber's observations, most accurately recognized at the parts which were determined to be most sensible by the foregoing method of inquiry.†—It has been since found, however, by Prof. Valentin, who has followed up and extended Prof. Weber's observations, that considerable amount of individual variation exists in regard to the "limit of confusion;" some persons being able to distinguish the points at one-half or even one-third of the distances required by others. Czermak‡ has drawn attention to many curious facts in relation to the "sense of space" or "locality" possessed by the skin; and has particularly shown that two points may be much more closely approximated, and yet distinguished as two, if they are applied one after the other, than if they are applied together; and again, that the points can be distinguished as two, at a shorter distance when gradually approximated from a considerable interval, than if they are gradually separated from an inappreciable interval. If one of the points be much colder than the other, the distance at which they can be distinguished is reduced, but their relative position cannot be accurately estimated. Moistening the skin with an indifferent fluid augments its sensibility. The delicacy of the sense of touch is diminished if the skin be either artificially or naturally stretched; hence the skin of the belly is less sensitive during pregnancy than under ordinary circumstances, and this may also in some measure serve to explain the diminution in sensibility which occurs in the passage from childhood to adult age, though the difference is no doubt partially due to the increased thickness of the epithelium. The theory of the sense of touch which has been suggested by Fick, is that each nerve-fibril breaks up into a pencil of fine filaments at the periphery, which are distributed over a certain space, perhaps on the average about 1-25th of an inch in diameter. An impression made upon any one of these filaments conveys the same sensation to the sensorium, providing no other nerve be distributed to the same space; but this hardly ever occurs, and hence compound sensations arise, by which our perception of the precise spot of the skin touched by a point is accurately determined. Thus, if we suppose the distribution of nerves to be represented by the circles, A, B, C, (Fig. 251) single sensations

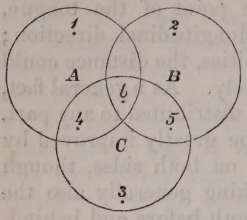
* See Klug in Du Bois-Reymond's "Archiv. f. Physiologie," Jahrg. 1877, p. 275.

† See his Memoir "De Pulsu, Respiratione, Auditu, et Tactu," Lipsiæ, 1834. See also "Récherches sur la Distribution de l'Organe du Sens Tactile," by M. H. Belfield-Lefèvre, Paris, 1837; and Prof. Valentin's "Lehrbuch der Physiologie des Menschen," Band ii. 566. —In the Author's article "Touch" in the "Cyclopædia of Anatomy and Physiology," vol. iv. p. 1169, will be found a Table including the whole series of observations made by Profs. Weber and Valentin, the maxima and minima of the latter being stated, as well as the means.

‡ "Sitz.-ber. der Wiener Akad.," Band xvii. p. 563, Band xxiv. p. 231; and Moleschott's "Untersuch.," Band i. p. 188.

would be produced if a point were applied at 1, 2, or 3, but a compound sensation would be produced if contact were made at 4 or 5, for the fibrils of two nerves, A and C, or B and C, would be implicated; whilst if the impression were made at 6, a still more complex sensation would arise, for then the peripheral branches of three of these nerves would be affected; in all instances a difference in the character of the impression capable of recognition by the mind being produced. It is obvious that the closer these "sensory circles" are, and the more intimately the branches of different nerves are intercalated with one another, the greater will be the accuracy of the sense of locality of that part, or, in other words, the greater will be the facility with which minute differences in the precise spot touched will be appreciated. The experiments of Dr. Paulus* show that the sensitiveness of the skin of the lower extremity, in accordance with a theory propounded by Vierordt, increases with its distance from the axis of rotation of the limb, or, in other words, from the proximal joint, and with the freedom with which its movements can be executed. The leg is thus more sensitive than the thigh, the foot than the leg, and the toes than the foot, the sensitiveness in each division again augmenting from its own proximal joint, except in the single case of the leg proper, where the minimum acuteness is opposite the centre of the tibia; but this, as Paulus points out, really favours Vierordt's theory, since, under different circumstances, sometimes the upper and sometimes the lower part of the leg moves through the greatest arc. In the arm the increase of sensitiveness from the shoulder to the tips of the fingers is as 1 : 24; in the legs as 1 : 8½, which may be accounted for by the greater rapidity required in the movements of the arm as compared with those of the leg. Tactile sensibility is diminished by cold, anæmia, congestion (as by venous compression), long and frequent experimentation (probably owing to exhaustion) and by narcotics, as Atropin, Daturin and Morphia, and by Strychnin and Alcohol.*

Fig. 251.



549. As already stated (§ 544), the ideas communicated to our minds by the sense of Touch, when exercised in its simplest form, are those of *Resistance* and *Temperature*, and it is by the various degrees of resistance which the sensory surface encounters, of which we partly judge by the muscular sense, that we estimate the hardness or softness of the body against which we press. It is only when either the sensory surface or the substance touched is made to change its place in regard to the other, that we obtain the additional notion of *extension* or *space:* this also being derived from the combination of the muscular with the tactile sense. By the impression made upon the papillæ, during the movement of the tactile organ over the body which is being examined, the roughness, smoothness, or other peculiar *characters of the surface* of the latter are estimated. Our knowledge of *form*, however, is a very complex process, requiring not merely the exercise of the sense of touch, but also great attention to the muscular sensations.—It is chiefly, as formerly remarked, in the *variety* of movements of which the hand of Man is capable, that it is superior to that of any other animal; and it cannot be doubted that the sense of Touch thus employed, affords us a very important means of acquiring information in regard to the external world, and especially of correcting many vague and fallacious notions which we should derive from the

* Paulus, "Zeitschrift f. Biologie," Band vii. p. 237; see also Kottenkamp and Ullrich, idem, Band vi. p. 37; and Klug, Op. cit.

† Landois, "Lehrbuch der Physiologie," 1880, p. 883.

sense of Sight, if used alone. On the other hand, it must be confessed that our knowledge would have a very limited range if this sense were the only medium through which we could acquire ideas. It is probably on the sensations communicated through the Touch that the idea of the material world, as something external to ourselves, chiefly rests; but this idea is by no means a logical deduction from our experience of these sensations, being rather an instinctive or intuitive perception directly excited by them.

550. Various experimenters* have endeavoured to determine the accuracy with which the Skin can appreciate impressions of weight or pressure when unassisted by the "muscular sense," that is, when the part experimented on is well supported, as when the hand is laid upon a table, and Eulenburg has constructed a Baræsthesometer, with which pressure can be applied by means of a spring. Eulenburg found that the brow, lips, dorsum of the tongue, cheeks and temples could appreciate a difference of from 1-48th to 1-30th of a given weight (200 : 205—300 : 310 gramme). The dorsal side of the last phalanx of the fingers of the fore-arm and of the hand, the palmar surface of the hand, and the front surface of the fore and upper arm recognized differences of pressure amounting to from 1-10th to 1-20th of the weight applied. The foot and the outer surface of the thighs were much less sensitive. Aubert and Kammler found that on the face and dorsal surface of the upper extremity, the pressure of a portion of elder-pith, presenting a surface of nearly one-third of an inch square, and weighing only 1-33rd of a grain (2 mgrm.), could be distinguished; whilst the tips of the fingers required a weight, presenting the same superficies, of 1-3rd of a grain or more, and the toes as much as 8 grains, before any sensation of pressure was felt. The presence of the minute hairs on the face was, however, found materially to augment its sensibility, since when these were shaved off it was much diminished.—According to Weber, differences in the amount of pressure are more accurately distinguished if they are applied successively to the same point, than if they are estimated coetaneously. The interval, however, must not be more than a few seconds, unless the difference be considerable. Thus, when 4 ounces and 5 ounces were successively applied, an accurate judgment of the difference might be made after 90 seconds; but the difference between 14·5 and 15 ounces could not be accurately determined after 40 seconds. If the bare sense of pressure were assisted by the muscular sense, as in cases when the hand was unsupported, much finer discrimination was always displayed. Thus on lifting a cloth in which weights were concealed, Weber found that ten people correctly indicated that a weight of 80 ounces was heavier than one of 78 ounces. Both Weber and Fechner† appear to have satisfactorily shown that with light weights smaller differences are perceived than with heavy weights. Thus supposing that *ounce* weights are distinguishable in the ratio of 29 to 30—*i.e.*, that a weight of 29 ounces can be discriminated when attentively examined from one of 30 ounces, a whole ounce requiring to be added or substracted before certainty is attained; when *drachms* are employed the same ratio still subsists, so that in this instance the removal or addition of one drachm to a weight of 30 drachms can be accurately appreciated. Dohrn endeavoured to ascertain the smallest additional weight that could be perceived by different parts of the body loaded with a weight of one gramme. He found that for the third phalanx of the fingers it was 0·499 gramme, for the dorsum of the foot 0·5 gramme, for the second phalanx of the fingers it was 0·771 gramme, for the first phalanx of the fingers it was 0·82 gramme, for the lower part of

* Auber and Kammler, Moleschott's "Untersuch.," Band v. p. 145; Dohrn, "Zeits. f. rat. Med.," 1860. † "Elemente der Psychophysik," 1860.

the thigh 1 gramme, for the back part of the hand 1·156 grammes, for the fore-arm 1·99 grammes, for the sternum 3 grammes, for the umbilical region 3·5 grammes, and for the back 3·8 grammes. Meissner has drawn attention to the fact, which must be familiar to most persons, that if the hand or foot be immersed in warm water or mercury, the only sensation experienced is that of a ring surrounding the limb at the surface of the fluid. The effect is, as he suggests, probably due to the circumstance that the pressure is applied in such cases with perfect uniformity over the part immersed, and therefore causes no disturbance of the nervous elements, the tactile sense being only excited at the line where the pressure produced by the fluid is that exchanged for that of the air.—Valentin* has endeavoured to ascertain the duration of a momentary excitation of the sense of Touch by rolling a spiked wheel over the skin; when slowly rotated, the contact of each spike was clearly discerned; but when only 1-640th of a second intervened between the successive blows, they could no longer be distinguished.—M. Lalanne,† adopting the same method, found the duration of tactile sensations to be considerably greater. The shortest duration observed was about 1-24th or 1-25th of a second, and it never surpassed 1-10th; some differences occurred, according to the individaul and the part of the body experimented on.—That the conditions under which certain of the modifications of common sensation operate, are in some respects different from those of ordinary Touch, is very easily shown. Thus, the feeling of tickling is excited most readily in parts which have but a low tactile sensibility—namely, the armpits, flanks, and soles of the feet; whilst in the points of the fingers, whose tactile sensibility is most acute, it cannot be excited. Moreover, the nipple is very moderately endowed with ordinary sensibility; yet by a particular kind of irritation, a very strong feeling may be excited through it.—Again, in regard to Temperature, it is remarked by Weber that the left hand is more sensitive than the right; although the sense of touch is undoubtedly the most acute in the latter. He states that if the two hands, previously of the same temperature, be plunged into separate basins of warm water, that in which the left hand is immersed will be felt as the warmer, even though its temperature is somewhat lower than that of the other. In regard to the sensations of heat and cold, he points out another curious fact—that a weaker impression made on a large surface seems more powerful than a stronger impression made on a small surface; thus, if the forefinger of one hand be immersed in water at 104°, and the whole of the hand be plunged in water at 102°, the cooler water will be thought the warmer; whence the well-known fact, that water in which a finger can be held will scald the whole hand. Hence it also follows, that minute differences in temperature, which are imperceptible to a single finger, are appreciated by plunging the whole hand in water; in this manner a difference of one-third of a degree may readily be detected, when the same hand is placed successively in two vessels. The judgment is more accurate, when the temperature is not much above or much below the usual heat of the body; just as sounds are best discriminated, when neither very acute nor very grave.

551. The pathological observations of M. Brown-Sequard‡ strongly support the view that separate conductors for sensations of pain, tickling, and temperature do exist, and he even believes he has demonstrated that the nerves conducting these four kinds of impression from the inferior extremities and

greater part of the trunk after decussation are situated in the upper part of the Spinal cord, behind the corresponding group belonging to the upper limbs and the neck. Horvath* has made the curious observation, that if the fingers be kept for some time in alcohol, only a few degrees (8°) above the freezing point, whilst the tactile sensibility is retained, the prick of a needle is not felt. The experiments made by Weber† to determine whether there are special conductors for temperature, in which he applied spatulas of different temperature (48° and 122° F.) to the surface of the skin denuded of its integument by a burn, and found that only pain was experienced, are of little value. It is remarkable, however, that we cannot excite impressions of heat or cold by direct application to the trunks of nerves which we know must conduct such impressions; for the parts of the skin, immediately beneath which lie large nerve-trunks, are not more sensitive to moderate heat and cold than are any others; whilst a greater degree of either is felt as pain, not as a change of temperature. Thus, a mixture of ice and water applied over the ulnar nerve affects it in fifteen seconds, and produces severe pain, having no resemblance to cold, and such as cannot be excited by the same degree of cold applied to any other region. So the nerve of the tooth-pulp is equally and similarly affected by water of 43° and of 112°; either application causing a pain exactly similar to that excited by the other, or to that produced by pressure. The same is true of the impressions received through the skin itself, when they pass beyond certain limits of intensity; thus, the sensation produced by touching frozen mercury is said to be not distinguishable from that which results from touching a red-hot iron. Wunderli‡ and Fick, moreover, found that sensations of heat, even in the most sensitive parts of the body, were sometimes mistaken for those of contact. Thus, in the case of the hand, an erroneous conclusion was arrived at six times out of 105 trials, and on the back twelve times in 30 experiments. The perception of variations of temperature does not extend in the mucous membranes far beyond their external orifices; and Weber found that on drinking a tumbler of water at 32° F., he felt the cold water in the mouth and pharynx, though its passage into the stomach could not be perceived. There was, it is true, a slight sensation of cold in the gastric region, but as it only occupied the situation of the anterior wall of the stomach, it was attributable to the abstraction of heat from the abdominal integuments in contact with this. On drinking three glasses of milk at 158°, 145°, and 140°, the sensation of heat could not be traced lower down than that of the cold in the previous experiment. In like manner, the injection of fourteen ounces of water at 65° into the rectum, produced scarcely any sensation of cold, though on its return, a few minutes afterwards, a distinct feeling of cold at the anus. When water at so low a temperature as 45·5° F. was injected, the first feeling excited was a sensation of cold in the immediate neighbourhood of the anus, and then a feeble movement in the bowels; but, a little time afterwards, there was a faint sensation of cold, especially in the anterior wall of the abdomen. This sensation, however, remained after the return of the water; and may hence be attributed to the abstraction of warmth from the abdominal integuments, which was proved to have taken place, the temperature of the surface being lowered 3°. So, again, if the cavity of the nose be filled with cold water, the coldness is only perceived in the parts of the cavity which are most endowed with the proper tactile sense—namely, the neighbourhood of the nostrils and

* "Centralblatt," 1873, p. 208. † Müller's "Archiv," 1849, p. 273.
‡ Henle and Meissner's "Bericht," 1859, p. 632.

of the pharynx; and it is not at all discernible in the higher part of the cavity, which is especially subservient to the olfactory sense. But when the water injected is very cold (*e.g.* 41°), a peculiar pain is felt in the upper part of the nasal fossæ, extending to the regions of the forehead and the lachrymal canals; this pain, however, is altogether different from the sense of coldness. The eyelids, cheeks, and temples, can distinguish variations of temperature amounting to not more than from 0·4° to 0·2° C. The hand and finger are about equally sensitive, but are less so than the forearm, and this again is exceeded by the upper arm, which can distinguish a difference of 0·2° C., and the same holds good of the foot, leg, and thigh. In Nothnagel's* extensive series of experiments, it was found that slight differences of temperature are most acutely recognized between 80° and 91° Fahr.

552. The improvement in the sense of Touch, in those persons whose dependence upon it is increased by the loss of other senses, is well-known; and the remarkable circumstance noticed by Volkmann,† that the increased sensitiveness which results from frequent experiments made upon one side of the body is experienced also in the nerve-fibres distributed to the opposite and exactly symmetrical parts, seems to show that the improved delicacy of the sense is to be in part attributed (as already remarked) to the increased attention which is given to the sensations, and in part, it may be surmised, to an increased development of the tactile organs themselves, resulting from the frequent use of them. The process of the acquirement of the power of recognizing elevated characters by the touch, is a remarkable example of this improvability. When a blind person first commences learning to read in this manner, it is necessary to use a large type; and every individual letter must be felt for some time, before a distinct idea of its form is acquired. After a short period of diligent application, the individual becomes able to recognize the combination of letters in words, without forming a separate conception of each letter; and can read line after line, by passing the finger over each, with considerable rapidity. When this power is once thoroughly acquired, the size of the type may be gradually diminished: and thus blind persons may bring themselves, by sufficient practice, to read a type not much larger than that of an ordinary large-print Bible. The case of Saunderson, who, although he lost his sight at two years old, became Professor of Mathematics at Cambridge, is well-known; amongst his most remarkable faculties, was that of distinguishing genuine medals from imitations, which he could do more accurately than many connoisseurs in full possession of their senses. Several instances are recorded of men who became eminent as sculptors after the loss of their sight, and who were particularly successful in modelling portrait-busts; hence, it is obvious, not merely the *tactile* but the *muscular* sensibility must be greatly augmented in acuteness by the habit of attending to it. The power of immediate recognition of individuals by the slightest contact of the hands, even after long periods of time, which most blind and deaf persons have displayed, is one of the most curious examples of the mode in which tactual perceptions will impress themselves on the memory, when they are habitually attended to. As an example of the correct notions which may be conveyed to the mind, of the forms and surfaces of a great variety of objects, and of the sufficiency of these notions for accurate comparison, the Author may mention the case of a blind friend of his own who has acquired a very complete knowledge of conchology, both recent and fossil; and who is not only able to

* "Deutsches Archiv f. Klin. Med.," Band ii. p. 284.

† Volkmann, "Uber der Einfluss der Uebung auf das Erkennen raümlicher Distanzen," "Bericht der Sachs. Gesell.," 1858.

recognize every one of the numerous specimens in his own cabinet, but to mention the nearest alliances of a shell previously unknown to him, when he has thoroughly examined it by his touch. Many similar instances might be cited, one of the most remarkable being that of John Gough, who, although blind, was a noted botanical collector, and earned his livelihood as a land surveyor. Several cases are on record* of the acquirement by the blind of the power of distinguishing the *colours* of surfaces which were similar in other respects, and, however wonderful this may seem, it is by no means incredible. For it is to be remembered, that the difference of colour depends upon the position and arrangement of the particles composing the surface, which render it capable of reflecting one ray whilst it absorbs all the rest; and it is quite consistent with what we know from other sources, to believe that the sense of Touch may become so refined, as to communicate a perception of such differences.†

3. *Sense of Taste.*

553. The sense of Taste is that by which we distinguish the *sapid* properties of bodies. The term, as commonly understood, includes much more than this; being usually employed to designate the whole of that knowledge of the qualities of a body (except such as is purely tactile), which we derive through the sensory apparatus situated within the mouth. But it will be hereafter shown that a considerable part of this is dependent upon the assistance of the *olfactive* sense (§ 559); which is affected, through the posterior nares, by the odorous emanations of all such bodies as are capable of giving them off; and the indications of which are so combined with those of the true gustative sense, as to make an apparently single impression upon the Sensorium. Moreover, there are certain sensorial impressions received through the organ of taste, which are so nearly allied in their character to those of *touch*, as to render it difficult to specify any fundamental difference between them; such are the *pungent* sensations produced by mustard, pepper, the essential oils, &c.; all of which substances, when applied for a sufficient length of time to any part of the cutaneous surface, produce a sensation which can scarcely be distinguished from that excited through the organ of taste, in any other way than by its inferior intensity, and by the absence of the concurrent odorous emanations. The *taste* of such substances might therefore, perhaps, be considered as the composite result of the impressions made upon the sensorium through a refined and acute *touch*, and by the effect of their odorous emanations upon the organ of *smell*. After making full allowance, however, for all such as can be thus accounted for, there remains a large class of pure *sapors*, of which we take cognizance without the assistance of smell, and which are altogether dissimilar to any tactile impressions; such are the *bitter* of quinine, the *sour* of tartaric acid, the *sweet* of sugar, the *saline* of common salt, &c. The smell can give us no assistance in distinguishing small particles of these bodies, since they are either entirely inodorous, or so nearly so, as only to be recognizable through its means when in large masses; and the most refined touch cannot afford any indication of that kind of difference among them, of which we are at once rendered cognizant by taste.—Of all the 'special' senses, however, that of Taste is most nearly allied to that of touch,

* Among the best authenticated of these, is that of a lady who became blind, and afterwards deaf, in consequence of an attack of confluent small-pox; cited in Dr. Kitto's "Lost Senses," vol. ii. p. 79, from the "Annual Register" for 1758.—Dr. Kitto's treatise may be referred to, as containing a large collection of interesting cases of a similar description.

† For some additional details in regard to the sense of Touch, see the Author's article "Touch" in the "Cyclopædia of Anatomy and Physiology," vol. iv.

as appears from several considerations. In the first place, the *actual contact* of the object of sense with the organ through which the impresssion is received, is necessary in the present case, as in the preceding. Again, it appears from the considerations formerly adduced (§ 493), that there is no special nerve of Taste; for the gustative impressions upon the front of the tongue are conveyed by the Lingual branch of the Fifth pair, and the branches of the Facial running in the Chorda tympani,* whilst those made upon the back of the organ are conveyed by the Glosso-pharyngeal, both of which nerves also minister to common sensibility; and pressure on the trunk of either of these nerves gives rise to pain, which is not the case with either the olfactory, the optic, or the auditory nerves. Moreover, the papillary apparatus, through which the gustative impressions are made upon the extremities of these nerves, is essentially the same in structure with that of the skin.†

554. For the Gustative nerve-fibres to be impressed by the distinctive properties of sapid substances, it appears requisite that these substances should be brought into immediate relation with them, and that they should penetrate, in the state of solution, through the investments of the papillæ, into their substance. This would seem to be proved by the two following facts: first, that every substance, whether solid, fluid, or gaseous, which possesses a distinct taste, is more or less soluble in the fluids of the mouth, whilst substances which are perfectly insoluble do not make their presence known in any other way than through the sense of touch; and, second, that if the most sapid substance be applied in a dry state to the papillary surface, and this be also dry, no sensation of taste is excited. Hence it may be inferred that in the reception of gustative impressions, a change is produced in the molecular condition of the nerve-fibres, or, to use the language of Messrs. Todd and Bowman, their polarity is excited by the direct agency of the sapid matter itself. This change may be induced, however, both by electrical and by mechanical stimulation. If we make the tongue form part of a galvanic circuit, a peculiar sensation is excited, which is certainly allied rather to the gustative than to the tactile, and which does not seem to be due (as was at one time supposed) to the decomposition of the salts of the saliva. And, as Dr. Baly has pointed out,‡ "if the end of the finger be made to strike quickly, but lightly, the surface of the tongue at its tip, or its edge near the tip, so as to affect not the substance of the organ, but merely the papillæ, a taste sometimes acid, sometimes saline, like the taste produced by electricity, will be distinctly perceived. The sensation of taste thus induced will sometimes continue several seconds after the application of the mechanical stimulus." On the other hand, as

* Lussana, "Centralblatt f. d. Med. Wiss.," 1871, p. 233.

† For some pathological cases bearing upon the question of the implication of the chorda tympani in the sense of taste, see Inzani and Lussana, in the "Annali Universali di Med.," 1862, pp. 282–322; Stich, in Henle and Meissner's "Bericht," 1857, p. 588; whilst for experimental evidence to the same effect, see Schiff, "Untersuch. zur Naturlehre," Band x. p. 406, and E. Neumann, "Königsberger Medic. Jahrb.," Band iv. p. 1. The two former observers believe the chorda tympani to be the true nerve of taste for the anterior part of the tongue, by which sweet, saline, piquant, and aromatic flavours are distinguished, whilst the mineral acids, astringents, bitters, pungent, putrefactive, and disgusting flavours are chiefly perceived through the glosso-pharyngeal. Schiff, "Physiologie," 1859, p. 403, thinks the Glosso-pharyngeal nerves are especially adapted to perceive bitter, and the Fifth nerves, acid tastes. Moos, "Centralblatt," 1867, No. 46, records a case where modifications of the sense of taste in the fore part of the tongue resulted from pressure on the chorda tympani, occasioned by the use of one of Toynbee's artificial tympana. Blau could excite a sourish taste and a quivering sensation by mechanical stimulation of the chorda tympani in a patient with perforation of the membrana tympani. "Berlin. Klin. Wochensch.," 1875, No. 45.

‡ Translation of Müller's "Physiologie," p. 1062, *note*.

Wagner has truly remarked, if the surface of the tongue near the root be touched with a clean dry glass rod, or a drop of distilled water be placed upon it, a slightly bitterish sensation is produced; and this, if the pressure be continued, passes into that of nausea, and if the pressure be increased, even excites vomiting. The feeling of nausea may be excited by mechanical irritation of any part of the surface of the fauces or soft palate; and this feeling is certainly much more allied to that of taste than to that of touch. Further, it has been observed by Henle, that if a small current of air be directed upon the tongue, it gives rise to a cool saline taste like that of saltpetre. Thus we find that the peculiar effects of sapid substances upon the nerves of taste may be imitated to a certain extent by other agencies; and it also appears that the sensations excited by these vary according to the part of the gustative surface on which they operate; mechanical or electrical stimulation of the front of the tongue giving rise to a kind of saline taste, whilst mechanical stimulation applied to the back of the tongue and fauces excites the feelings of bitterness and nausea.—One of the conditions requisite for the due exercise of the gustative sense is, a temperature not departing far on either side from that which is natural to the body. It appears from the experiments of Professor E. H. Weber,* that if the tongue be kept immersed for nearly a minute in water of about 125°, the taste of sugar brought in contact with it, either in powder or solution, is no longer perceived; the sense of touch, usually so delicate at the tip of the tongue, being also rendered imperfect. A similar imperfection of taste and touch was produced by immersing the tongue for the same length of time in a mixture of water and broken ice.

555. The surface of the Tongue is undoubtedly the special seat of gustative sensibility in Man; though the sense of Taste is not by any means restricted to that organ, being diffused in a less degree over the soft palate, the arches of the palate, and the fauces. It is on the tongue alone, however, that the papillary apparatus is fully developed; and its structure has been so carefully examined and described by Messrs. Todd and Bowman,† that little remains to be added to their account of it.—The lingual papillæ may be divided, in the first place, into the *Simple* and the *Compound*, the former of which had previously escaped observation, through not forming any apparent projection. The *Simple* papillæ are scattered, in the intervals of the compound, over the general surface of the tongue; and they occupy much of the surface behind the circumvallate variety, where no compound papillæ exist. They are completely buried and concealed beneath the continuous sheet of epithelium, and can only be detected when this membrane has been removed by maceration; they are then found to have the general characters of the cutaneous papillæ. The *Compound* papillæ are visible to the naked eye; and have been classified, according to their shape, into the *circumvallate*, the *fungiform*, and the *filiform*. The *circumvallate* or calyciform papillæ are eight or ten in number, and are situated in a V-shaped line at the base of the tongue. Each consists of a central flattened circular projection of the mucous membrane, surrounded by a tumid ring of about the same elevation, from which it is separated by a narrow circular fissure. The surface of both centre and border is smooth, and is invested by scaly epithelium, which conceals a multitude of simple papillæ. The *fungiform* papillæ, varying in number from 160 to 290,‡ are scattered singly over the tongue, chiefly upon its sides and tip. They project

* Müller's "Archiv," 1847, s. 342.
† "Physiological Anatomy and Physiology of Man," vol. i. chap. xv.
‡ Szabadföldy, Virchow's "Archiv," xxxviii. p. 177.

considerably from the surface, and are usually narrower at their base than at their summit. They contain a complex capillary plexus (Fig. 252), the terminal loops of which enter the numerous simple papillæ that clothe the surface of the fungiform body. Amidst these lie nerve-tubes, which probably terminate in free extremities between the epithelial cells, the epithelium itself being so thin as to allow the red colour of the blood to be seen through it. In this manner they are readily distinguished from the filiform papillæ among which they lie. The *filiform* papillæ, like the preceding, contain a plexus of capillaries and a bundle of nerve-fibres, both terminating in loops, which enter the simple papillæ that clothe the surface of the compound body; but instead of being covered with a thin scaly epithelium, they are furnished with bundles of long pointed processes, some of which approach hairs in their stiffness and structure. These are immersed in the mucus of the mouth, and may be moved in any direction, though they are generally inclined backwards.—The simple papillæ which occur in an isolated manner, may not improbably be tactile; while those which are aggregated in the circumvallate and fungiform bodies, doubtless minister to the sense of Taste, this being most acute in the situations wherein they most abound. With regard, however, to the office of the filiform papillæ, there seems much reason to coincide in the opinion of Messrs. Todd and Bowman:—"The comparative thickness of their protective covering, the stiffness and brush-like arrangement of their filamentary productions, their greater development in that portion of the dorsum of the tongue which is chiefly employed in the movements of mastication, all evince the subservience of these papillæ to the latter function, rather than to that of taste; and it is evident that their isolation and partial mobility on one another must render the delicate touch with which they are endowed more available in directing the muscular actions of the organ. The almost manual dexterity of the organ, in dealing with minute particles of food, is provided for, as far as sensibility conduces to it, in the structure and arrangement of these papillæ. It may be added, that the filiform papillæ of Man seem to be the rudimentary forms of those horny epithelial processes which acquire so great a development in the tongues of the Carnivora, and which are of such importance in the abrasion of their food. The mode of termination of the gustatory nerves has been the subject of much recent research. Engelmann* describes the glosso-pharyngeal nerves in Man and Mammals as terminating in peculiar organs, termed

The principal English references are Waller, "Philosophical Transact.," 1847; Lionel Beale, idem. 1865, and "Quart. Journ. of Microscop. Soc.," 1869; and R. L. Maddox, "Month. Microscop. Journal," 1869. And since the date of Engelmann's article, the following papers have appeared:—Ajtai, "Archiv f. Mic. Anat.," Band viii. p. 455; Ditlevsen, "Undersögelse," &c., Copenhagen, 1872;

gustatory bulbs, or taste-buds. These are flask-shaped bodies (Fig. 253), which are disposed in a zone encircling the sides of the papillæ circumvallatæ (Fig. 254), a few being also found on the outer wall of the vallecula, or that which looks towards the papilla. Schwalbe estimated the number present in one circumvallate papilla of the Sheep at 480, and in one such papilla from the Ox at 1760. They are also found, but more irregularly distributed, upon the fungiform papillæ. The bulbs are composed of groups of cells (Fig. 253), which occupy flask-shaped cavities in the mucous membrane. The bottom of the cavity is formed by the fibrous layer of the mucous membrane, its sides are composed of cells, and the slender short neck perforates the corneal lamina, opening on the surface by a small circular mouth, which may be called the *gustatory pore.* The length of the bulb is about 0·080 of a millimeter. The gustatory bulbs, which completely fill these spaces, are composed of two kinds of cells. Of these the outer, or *investing cells* (Fig. 255), from 15 to 30 in number, are fusiform, have a well-defined nucleus, and are arranged concentrically to the surface in closely-compressed rows. They enclose a group of cells which are believed to be the *true gustatory cells.* These have a long and thin body, with a large vesicular nucleus, from which a peripheric process runs, that either ends by an abruptly truncated extremity (rod or staff-cell), or in a very fine point (needle-cells), the apices projecting for some distance through the gustatory pore. The relations of these organs to the gustatory nerves has not been quite satisfactorily made out; but the finely medullated branches of the glosso-pharyngeal nerve, containing small groups of ganglion-cells, have been observed to form plexuses beneath the papillæ, from which one or more fasciculi are given off, that run up the axis of the papilla, and then break up into numerous fine branches which stream out towards the epithelium. In the Frog, cylindrical papillæ are present, which are composed below of loose, and near their free extremity of compact, connective tissue, forming a *nerve-cushion;* upon each of these lies a gustatory disc, the structure of which is analogous to that of the gustatory bulb, being resolvable into *goblet* and *columnar* supporting or protecting cells, and *forked* cells, which appear to be the continuation of the non-medullated nerve-fibres (Fig. 255).

556. The simple application of a sapid substance to the gustative surface is usually sufficient to excite the sensation; and if this application be restricted to one particular spot, we are able to recognize its place more or less distinctly. In this respect, then, the gustative impression resembles

Abstract in Schwalbe's "Jahresbericht," 1872. Hönigschmeid, "Zeitsch. für wiss. Zool.," Band xxiii. p. 414 and Band xxix. p. 255; Sertoli, "Gazetta Med.-Vet.," Anno iv. Sep. Abd. Leydig, see Ref. in Hofmann's "Jahres bericht," 1879, i. p. 31.

the tactile; for whilst we cannot by our own consciousness distinguish the parts of the retina or of the auditory apparatus on which visual or auditory impressions are made, we can make this distinction in regard to the surface which is supplied by the nerves of general sense. From the careful experiments of Stich and Klaatsch,* supported as they are by the results of other observations, we are now enabled to define with some accuracy the exact seat of the sense of taste. It exists over the whole surface of the posterior third of the dorsum of the tongue, on the under surface of the tip, and in a band or line, about one-quarter of an inch broad, running along its edge. The sense is also well defined in the posterior part of the hard palate, and in that portion of the soft palate which is near the bone, and lastly, in the anterior pillars of the fauces. The middle and anterior part of the dorsum, the gums, posterior pillars of the fauces, and the inner surface of the lips, possess no sense of taste, though exquisitely sensitive to tactile impressions. M. v. Vintschgau,† in summing up the results obtained by himself and other physiologists, has come to the following conclusions in regard to the sensation of Taste by the tip of the tongue. He finds that there are some persons who can distinguish all the chief sensations of Taste solely by the tip of the tongue. There are other persons who can perceive with certainty by means of the same part the sensations of sweetness, saltness, and acidity, but with less clearness the sensation of bitterness. There are again other persons who can only distinguish individual tastes with the greatest difficulty by the tip of the tongue, and to this category M. v. Vintschgau himself belongs. These individuals can distinguish an acid from a sweet with comparative ease, and a salt with more difficulty, but they either entirely fail to perceive a bitter, or if they do it is only with the utmost attention. Lastly, there is still another class of persons who are wholly incapable of perceiving any taste by the tip of the tongue. Bitters and acids appear to be the substances of which the dilution or attenuation may be carried to the greater extent, without ceasing to excite sensations of taste, providing a sufficient volume of the solution be introduced into the mouth. Thus, according to Valentin, one part of extract of aloes or sulphuric acid in 900,000 of water, and even one part of sulphate of quinine in 1,000,000 of water, may be distinguished if heedfully compared with perfectly pure water. The contact of a sapid substance much more readily excites a gustative sensation, when it is made to press upon the papillæ, or is moved over them. Thus there are some substances whose taste is not perceived when they are simply applied to the central part of the dorsum of the tongue, but of whose presence we are at once rendered cognizant by pressing the tongue against the roof of the mouth. The full flavour of a sapid substance, again, is more readily perceived when it is rubbed on any part of the tongue, than when it is simply brought in contact with it, or pressed against it, and Camerer has shown that the intensity of the gustatory sensations depends partly on the number of papillæ that are stimulated, and partly‡ upon the degree of concentration of the solution. Hence, when liquids are received into the mouth their taste is most completely discriminated by causing them to move over the gustative surface: thus the 'wine-taster' takes a small quantity of the liquor into his mouth, carries it rapidly over every part of its lining membrane, and then ejects it. It is not improbable that this exaltation of the usual effects is simply due to mechanical causes; the sapid particles being brought by the pressure or movement into more rapid and complete operation on the nerve fibres, than they would be if simply

* "Archiv f. Path. Anat.," Band xiv. 1858, p. 225, and Band xviii. p. 80.
† Pflüger's "Archiv," Band xiv p. 443. ‡ Camerer, "Zeits. f. Biologie," Band vi p. 440.

placed in contact with the papillæ. The rapidity with which sapid impressions are perceived has been made the subject of a series of experiments by Vintschgau and Hönigschmied.* The substances used were bisulphate of quinine, sugar, common salt, and diluted phosphoric acid. A small brush, about one-third of an inch square, was applied to the surface of the tongue. On being applied, an electrical current was made, which was broken by a movement of the hand as soon as the taste was perceived. When the tip of the tongue was thus excited, the following times were obtained:—Common salt, 0·1598 sec.; sugar, 0·1639; phosphoric acid, 0·1676; quinine, 0·2351.

557. The impressions made upon our consciousness by a large proportion of sapid substances are of a complex kind; being in part derived from their odorous emanations, of which we take cognizance through the organ of Smell. Of this any one may convince himself by closing the nostrils, and inspiring and expiring through the mouth only, whilst holding in the mouth, or even rubbing between the tongue and the palate, some aromatic substance; for its taste is then scarcely recognized, although it is immediately perceived when its effluvia are drawn into the nose. It is well known too, that when the sensibility of the Schneiderian membrane is blunted by inflammation (as in an ordinary 'cold in the head'), the power of distinguishing flavours is very much diminished. In fact, some physiologists are of opinion that *all* our knowledge of the *flavour* of sapid substances is received through the Smell; but this, as already shown, would not be a correct statement; and there are cases on record in which the sense of smell has been entirely lost, without any impairment of the true sense of Taste.†

558. Taken in its ordinary composite acceptation, the sense of Taste has for its object to direct us in the choice of food, and to excite the flow of mucus and saliva, which are destined to aid in the preparation of the food for Digestion. Among the lower animals, the instinctive perceptions connected with this sense are much more remarkable than our own; thus an omnivorous Monkey will seldom touch fruits of a poisonous character, although their taste may be agreeable; and animals whose diet is restricted to some one kind of food will decidedly reject all others. As a general rule it may be stated, that substances of which the taste is agreeable to us are useful in our nutrition, and *vice versâ*:‡ but there are many signal exceptions to this.—Like

* Pflüger's "Archiv," 1875, pp. 1–48.

† An interesting case of this kind, occurring in a Negro who had gradually lost the characteristic hue of his skin, and had acquired the fair complexion of a European, has been put on record by Dr. J. C. Hutchinson.—The Olfactory nerve seemed to be entirely paralyzed, whilst the branches of the Fifth Pair retained their integrity; so that, whilst the proper sense of Smell was entirely lost, a pungent burning sensation was excited by irritating vapours, and the application of snuff induced sneezing. Notwithstanding this deficiency, the sense of Taste, properly so called, did not seem to be impaired; for substances which possessed neither odour nor pungency could readily be discriminated, even though their tastes were not widely different. (See "Amer. Journ. of Med. Sci.," Jan. 1852.)

‡ It is justly remarked by Sir H. Holland ("Medical Notes and Reflections," p. 85) that,—"In the majority of instances of actual illness, provided the real feelings of the patient can be certainly ascertained, his desires as to food and drink may be safely complied with. But undoubtedly much care is needful that we be not deceived as to the state of the appetites, by what is merely habit or wrong impression on the part of the patient, or the effect of the solicitation of others. This class of sensations is more nurtured out of the course of Nature than are those which relate to the temperature of the body. The mind becomes much more deeply engaged with them; and though in acute illness they are generally submitted again to the natural law, there are many lesser cases where enough remains of the leaven of habit to render every precaution needful. With such precautions, however, which every physician who can take schooling from experience will employ, the stomach of the patient becomes a valuable guide; whether it dictate abstinence from a recurrence of food; whether much or little in quantity; whether what is solid or liquid; whether much drink or little; whether

other senses, that of Taste is capable of being rendered more acute by education; and this on the principles already laid down in regard to Touch. The experienced wine-taster can distinguish differences in age, purity, place of growth, &c., between liquors that to ordinary judgments are alike; and the epicure can give an exact determination of the spices that are combined in a particular sauce, or of the manner in which the animal on whose flesh he is feeding was killed. As in the case of other senses, moreover, impressions made upon the sensory surface remain there for a certain period; and this period is for the most part longer than that which is required for the departure of the impressions made upon the eye, the ear, or the organ of smell. Every one knows how long the taste of some powerful substances remains in the mouth; and even of those which make less decided impressions, the sensations remain to such a degree that it is not difficult to compare them at short intervals. Hence if a person be blindfolded, and be made to taste substances of distinct, but not widely-different flavours (such as various kinds of wine or spirituous liquors), one after another in rapid succession, he soon loses the power of discriminating between them. In the same manner, the difficulty of administering very disagreeable medicines may be sometimes got over, by either previously giving a powerful aromatic, or by combining the aromatic with the medicine; its strong impression in both cases preventing the unpleasant taste from exciting nausea.

4. *Sense of Smell.*

559. The Nasal passages may be considered as having, in air-breathing Vertebrata two distinct offices; for they constitute the portal of the Respiratory organs, and have for their office to take cognizance of the aëriform matter as it enters them, and to give warning of that which would be injurious (this being effected by the instrumentality of the Fifth pair), which receives the impressions of gaseous irritants, and excites the act of sneezing to expel them; whilst they also contain the organ of Smell, which is formed by the distribution, over a certain part of their membranous wall, of the *Olfactory* nerve, which is susceptible of being impressed by odorous emanations. Of the nature of these emanations the Physical Philosopher is so completely ignorant, that the Physiologist cannot be expected to give a definite account of the mode in which they produce sensory impressions. Although it may be surmised that they consist of particles of extreme minuteness, dissolved as it were in the air, and although this idea seems to derive confirmation from the fact that most odorous substances are volatile, and *vice versâ*—yet the most delicate experiments have failed to discover any diminution in weight, in certain substances (as musk) that have been impregnating a large quantity of air with their effluvia for several years; whilst there are some volatile fluids, such as water, which to man are entirely inodorous. Nearly all the

things warm or cold; whether sweet, acid, or saline; whether bland or stimulating to the taste." Further, Sir H. Holland remarks: "It is not wholly paradoxical to say that we are authorized to give greatest heed to the stomach, when it suggests some seeming extravagance of diet. It may be that this is a mere deprivation of the sense of taste; but frequently it expresses an actual need of the stomach, either in aid of its own functions, or indirectly (under the mysterious law just referred to) for the effecting of changes in the whole mass of blood. It is a good practical rule in such cases to withhold assent, till we find after a certain lapse of time that the same desire continues or strongly recurs; in which case it may generally be taken as the index of the fitness of the thing desired for the actual state of the organs. In the early stage of recovery from long gastric fevers, I recollect many curious instances of such contrariety to all rule being acquiesced in, with manifest good to the patient. Dietetics must become a much more exact branch of knowledge before we can be justified in opposing its maxims to the natural and repeated suggestions of the stomach, in the state either of health or disease.

vegetable odours belong to one or other of three categories—namely, hydrocarbons, aldehydes, or ethers. Many of them are capable of being artificially formed, and they present good examples of Isomerism. Thus the essences of turpentine, citron, bergamot, neroli, juniper, savin, lavender, cubebs, peppermint, and cloves, all have the same composition, C_{10} H_{16}. Amongst the odoriferous essences that are ranged by chemists in the class of aldehydes are those of mint, rue, bitter almonds, cummin, anise, fennel, canella, and meadow-sweet. The ethers are very varied and complex in constitution. Linnæus arranged odours into seven classes:—Aromatic (laurel leaves); fragrant (jasmine); ambrosial (musk); alliaceous (garlic); fetid (stinking goosefoot); repulsive (solanaceæ); and nauseous odours. Such an arrangement is very imperfect, not including, for example, such well-marked odours as those of tar gas.* Prévost† has described two phenomena that are presented by odorous substances, the observation of which he has termed *odoroscopy*. One is, that odorous substances when placed on water begin, like particles of camphor, to move, owing to their emission of an elastic fluid into the air, and the other is that a thin layer of water, extended on a perfectly clean glass plate, retracts when such an odorous substance as camphor is placed upon it. Liegeois has further shown that the particles of an odorous body placed on water undergo a rapid division, and that the movements of camphor, or of benzoic acid, are inhibited, or altogether arrested if an odorous substance be brought into contact with the water on which they are moving.‡ The original motion of camphor he attributes to its emitting an oily fluid.§

560. The tractus olfactorius is exclusively composed of medullated nerve fibres which have a sheath of Schwann. It terminates on each side in the Olfactory ganglion, from which the Olfactory nerves pass down in the form of very numerous minute threads, which form a plexus upon the surface of the Schneiderian or pituitary membrane (Fig. 256.) The filaments composing this plexus are described by Messrs. Todd and Bowman‖ as differing widely in structure from those of the ordinary cephalic nerves; they contain no white substance of Schwann, are nucleated and finely granular in texture, and altogether bear a close resemblance to the gelatinous form of nerve fibres (Fig. 256). The mode in which these nerves terminate has recently been the subject of close investigation by several observers.¶ Their distribution appears to be limited to the membrane covering the upper third of the septum of the nose, the superior turbinated bone, and perhaps the upper part of the middle turbinated bone; together with the upper wall of the nasal cavities beneath the cribriform plate of the ethmoid bone; all which surface is

¶ Hoyer, Henle and Meissner's "Bericht," 1857, p. 27; Schultze, "Untersuchungen über den Bau der Nasenschleimhaut," Halle, 4to; Lockhart Clarke, "Zeits. f. wissens. Zool.," Band xi. For an abstract of this paper, see "Med.-Chir. Review" for 1862, vol. i. p. 521. See also Exner, "Sitz. d. k. Akad. zu Wien," 1870 and 1872. Exner denies the distinctness

covered (as Messrs. Todd and Bowman have pointed out) with an epithelium of a rich sepia-brown hue, constituting the *regio olfactoria* of Babuchin. According to Schultze these epithelial cells are divisible into two sets: one of these (*a*, Fig. 257) may be described as terminating externally by truncated flat surfaces which cannot be observed to be covered by any membrane separate from the contents of the cell. The contents themselves appear to consist of protoplasm presenting a yellowish granular appearance in the outer part, whilst at the lower part an oval nucleus lying in clear protoplasm can be readily distinguished. Towards their attached extremity these cells become attenuated, and can be traced inwards for a considerable distance, when they expand into a broad flat sheet or plate, which, whilst it frequently presents a granular appearance, is never coloured. The processes which pass off from this sheet appear to be continuous with the fibres of the submucous connective tissue. Towards the margin of the true olfactory region, cells (*c*, Fig. 257) in every respect analogous to those just described are found, excepting only that they present a well-defined band or seam at their free extremity, which is surmounted by a circle of cilia.—The cells of the second set (*b*, Fig. 257) have been described by Schultze and Babuchin as continuations of the nerves, and have hence been termed by them 'Olfactory cells.' They are thin, fibrous, or rod-like bodies, terminating at the same level as the proper epithelial cells in a leash of long fine cilia (Babuchin), and presenting when traced inwards a large oval nucleus and a series of moniliform or varicose swellings which are directly continuous with outrunners of more deeply seated nerve cells. Closely analogous appearances have been seen and described by Lockhart Clarke, who states that the Olfactory nerve-fibres on reaching the base of the epithelial layer divide into finer and still finer branches, to form a network with numerous interspersed nuclei, through which they are probably connected with the 'Olfactory cells' (*f*, Fig. 257). The proper epithelial cylinders (*d*, *e*) are connected at their bases with the septa formed of connective tissue belonging to the sub-epithelial glandular layer.—The remainder of the nasal surface constituting the 'Regio respiratoria' is supplied by the Fifth pair only, and is not endowed with sensibility to odours, although it is susceptible of irritation from such as are of a pungent nature; and hence it is that we cannot distinguish faint odours, unless, by a peculiar inspiratory effort, we draw the air charged with them to the upper part of the nose. In animals living in the air, it is a necessary condition of the exercise of the sense of Smell, that the odorous matter should be transmitted by a respiratory current through the nostrils, and that the membrane lining these should be in a moist state. Hence by breathing through the mouth, we may avoid being affected by odours even of the strongest and most disagreable kind; and in the first state of a catarrh, when the ordinary mucous secretion is suspended, the sense of Smell is blunted from this cause, as it afterwards is from the excess in the quantity of the fluid, which prevents

FIG. 257.

of the two forms of cells described in the text (§ 560); Babuchin, Stricker's "Human and Comp. Histology," Syd. Soc. Trans., 1873, vol. iii. p. 201,; Paschutin, "Leipziger physiol. Arbeiten," 1873, p. 41; Cisoff, "Centralblatt für die Med. Wissenchaften," 1874, p. 689; Martin, "Journ. of Anat. and Physiol.," 1874, vol. viii. p. 39.

the odoriferous effluvia from coming into immediate relation with the sensory extremities of the nerves. Hence we may easily comprehend how sections of the Fifth pair, which exerts a considerable influence over the secretions, will greatly diminish the acuteness of this sense, and will have the further effect of preventing the reception of any impressions of irritation from acrid vapours, which are entirely different in their character from true odorous impressions, and are not transmitted through the Olfactory nerve.

561. The Olfactory nerve can be stimulated by electricity, and by its own special stimuli, but not apparently by heat or by mechanical irritation. Ritter* found that the application of the negative pole to the nose produces a disposition to sneeze, and sometimes a faint smell of ammonia, whilst the positive pole removed the tendency to sneeze, and induced a dull sensation, with sometimes an acid odour. The importance of the sense of Smell among many of the lower Animals, in guiding them to their food, or in giving them warning of danger, and also in exciting the sexual feelings, is well known. To man its utility is comparatively small under ordinary circumstances; but it may be greatly increased when other senses are deficient. Thus, in the well-known case of James Mitchell, who was blind, deaf and dumb, from his birth, it was the principal means of distinguishing persons, and enabled him at once to perceive the entrance of a stranger. It is recorded that a blind gentleman, who had an antipathy for cats, was possessed of a sensibility so acute in this respect, that he perceived the proximity of one that had been accidentally shut-up in a closet adjoining his room. Among savage tribes, whose senses are more cultivated than those of civilized nations, more direct use being made of the powers of observation, the scent is almost as acute as in the lower Mammalia; thus it is asserted by Humboldt, that the Peruvian Indians in the middle of the night can distinguish the different races, whether European, American-Indian, or Negro; and the Arabs of the Great Desert are said to be able to distinguish the smell of a fire thirty miles off.—The quantity of some odorous

* Quoted in Hermann's "Handbuch der Physiologie," 1880, Band iii. pt. ii. p. 255.

bodies which is capable of exciting a distinct perception of Smell, must in some instances be exceedingly small. A very minute trace of sulphuretted hydrogen is readily recognised, and according to Valentin, one part of bromine in 200,000 of air communicates an unpleasant odour to the latter, whilst in the case of musk a proportion not greater than one part in 13,000,000 of air is still perceptible.—The agreeable or disagreeable character assigned to particular odours, is by no means constant amongst different individuals. Just as many of the lower animals pass their whole lives in the midst of odours that are to Man (in his civilized condition at least) in the highest degree revolting, and will even refuse to touch food until it is far advanced in putridity, so do we find that men who are compelled by circumstances to live upon putrescent food, come at last to relish it most when it is furthest advanced in decomposition and the most refined epicures among highly-civilized communities seem to find pleasure in similar odours and savours, which to ordinary tastes are anything but agreeable.—As to the length of time during which impressions made upon the organ of Smell remain upon it, no certain knowledge can be obtained. It is difficult to say when the effluvia themselves have been completely removed from the nasal passages, since it is not unlikely that the odorous particles (supposing such to exist) are absorbed or dissolved by the mucous secretion ; it is probably in this manner that we may account for the fact, well known to every medical man, that the cadaverous odour is frequently experienced for many days after a post-mortem examination.*

5. *Sense of Vision.*

562. The objects of this sense are bodies from which Light proceeds, either because they are luminous in themselves, or because they reflect the light that proceeds from other bodies. Whether their light is transmitted by the actual *emission* of luminous particles, or by the propagation of *undulations* analogous to those of sound, is a question that has been long keenly debated amongst Natural Philosophers; but it is of little consequence to the Physiologist *which* is the true solution, since he is only concerned with the laws according to which the transmission takes place, which are the same on both theories. These laws it may be desirable here briefly to recapitulate.

563. Every point of a luminous body sends off a number of rays, which diverge in every direction, so as to form (as it were) a cone, of which the luminous point is the apex. So long as these rays pass through a medium of the same density, they proceed in straight lines: but if they enter a medium of different density, they are *refracted* or bent—*towards* the perpendicular to the surface at the point at which they enter, if they pass from a rarer into a denser medium—and *from* the perpendicular, when they pass from a denser medium into a rarer. It is easily shown to be a result of this law, that, when parallel rays passing through air fall upon a convex surface of glass, they will be made to converge ; so as to meet at the opposite extremity of the diameter of the circle, of which the curve forms part. If, instead of continuing in the glass, they pass-out again, through a second convex surface, of which the direction is the reverse of the first, they will be made to converge still more, so as to meet in the centre of curvature. Rays which are not parallel, but which are diverging from a focus, are likewise made to converge to a point or focus; but this point will be more distant from the lens, in proportion as the

* This may partly be attributed also to the effluvia adhering to the dress. It has been remarked that *dark* cloths retain these more strongly than *light*. For some sensible observations on the sense of smell in the diagnosis of disease, see D. W. Crompton in the "Birmingham Medical Review," No. viii., Oct. 1873, p. 251, and No. ix. p. 23.

object is nearer to it, and the angle of divergence consequently greater. The rays diverging from the several points of a luminous object, are thus brought to corresponding foci; and the places of all these foci hold exactly the same relation to each other, with that of the points from which the rays diverged; so that a perfect image of the object is formed upon a screen held in the focus of the lens. This image, however, will be inverted; and its size, in proportion to that of the object, will depend upon their respective distances from the lens. If their distances be the same, their size will also be the same; if the object be distant, and the image near, the latter will be much the smaller; and *vice versâ*.

564. There are two circumstances, however, which interfere with the perfection of an image thus formed by a convex lens. The one is, that if the lens constitute a large part of the sphere from which it is taken, the rays which fall near its margin are not brought to a focus at the same point with those which pass through its centre, but at a point nearer the lens. This difference, which must obviously interfere greatly with the distinctness of the image, is termed *Spherical Aberration;* it may be corrected by the combination of two or more lenses, of which the curvatures are calculated to balance one another in such a manner that all the rays shall be brought to the same focus; or by diminishing the aperture of the lens by means of a stop or diaphragm, in such a manner that only the central part of it shall be used. The latter of these methods is the one employed where the diminution in the amount of light transmitted is not attended with inconvenience. The nearer the object is to the lens (and the greater, therefore, the angle of divergence of its rays), the greater will be the spherical aberration, and the more must the aperture of the diaphragm be reduced in order to counteract it.—The other circumstance that interferes with the distinctness of the image, is the unequal refrangibility of the differently-coloured rays which together make up white or colourless light; the violet being more bent from their course than the blue, the blue more than the yellow, and the yellow more than the red; the consequence of which will be, that the violet rays are brought to a focus much nearer to the lens than the blue, and the blue nearer than the red. If a screen be held to receive the image in the focus of any of the rays, the others will make themselves apparent as fringes round its margin. This difference is termed *Chromatic Aberration.* It is corrected in practice, by combining together lenses of different substances, of which the *dispersive* power (that is, the power of separating the coloured rays) differs considerably. This is the case with flint and crown-glass, for instance—the dispersive power of the former being much greater than that of the latter, whilst its refractive power is nearly the same; so that, if a convex lens of crown-glass be united with a concave of flint whose curvature is much less, the dispersion of the rays effected by the former will be entirely counteracted by the latter, which diminishes in part only its refractive power.*

* The most important recent works on the optical relations of the eye, are Helmholtz's "Handbuch der Physiologischen Optik," Leipzig, 1867; and the monographs by Merkel, Waldeyer, Schwalb and others in Gräfe and Sämesch's "Handbuch der Gesammten Augenheilkunde," 1874. MM. Hüppel and Grünhagen have shown ("Archives für Ophthalmol.," Band xiv. p. 219) that the ordinary pressure of the contents of the globe of the eye in the cat is sufficient to support a column of mercury of from 22–24 mm. in height. When the third nerve was irritated, the pressure rose from this average to 70–90 mm., which was apparently due to the contraction of the recti and obliquus inferior. Irritation of the branches supplying the sphincter iridis and ciliary muscle exerted no influence. Excitation of the cervical sympathetic was followed by a primary exaltation and a secondary diminution of pressure. The former effect, amounting to 1–6 mm., was probably due to the contraction of the retractor muscle; the latter appeared to result from contraction of the ocular vessels.

565. The eye commences as a protrusion of the forebrain, the base of the process becoming constricted to form the optic tract, chiasma, and nerve, whilst the peripheral extremity develops into the retina. In front of the retina are various transparent media, partly derived from the mesoblast and partly from the epiblast, the refractive power of which is adapted to form a sharply-defined image of external objects upon the retina. When fully developed, the optic nerves arise by three roots, two white and one grey. The external and larger white root runs to the corpus geniculatum externum, which is in immediate relation with the nates; whilst the internal white root runs into the corpus geniculatum internum, which is connected with the testes. The *external white* root, after entering the posterior part of the thalamus opticus, divides into three fasciculi, one running upwards by the side of the corpus geniculatum externum, to intermingle with the stratum zonale of the optic thalamus; a second enters the pulvinar, or posterior tubercle, after passing beneath the corpus geniculatum externum; whilst the third penetrates the corpus geniculatum externum opposite the optic nerve. The *internal white* root, after penetrating the corpus geniculatum internum, traverses it, and emerging at the opposite side, runs to the *nates*, and perhaps by a few fibres to the testes. The *grey root* may be traced to the grey matter of the third ventricle, which covers the opposed surfaces of the optic thalami. It forms a lamina, which passes obliquely to the upper surface of the optic chiasma. Bellouard* observes that through the stratum zonale of the optic thalamus, and through the inferior root of the thalamus, the optic nerve is brought into relation with the cortex cerebri, the fibres forming the optic radiations of the corona radiata. Through the pulvinar and its optic radiations, it is brought into relation with the cortex of the occipital lobes† and with the medulla by the fibres of the tegmentum of the cerebral peduncle. Other fibres extend from the nates and testes to the cortex cerebri. Collectively these fibres form a projection system of the first order. Stilling‡ also admits an origin from the tuber cinereum and another from the substantia perforata antica.

566. The refractive surfaces of the eye are three in number, and may be regarded as spherical, though the cornea has been shown to be slightly ellipsoidal. The radius of the first refracting surface, which is that of the cornea, is about 7·7 mm.; of the second, which is the anterior surface of the lens, is about 10·3 mm.; and of the third, which is the posterior surface of the lens, about 6·1 mm. The distances between these are: from the anterior surface of the cornea to the anterior surface of the lens varies from 2·0 to 3·1 mm.; the distance from the anterior surface of the cornea to the posterior surface of the lens, from 7·1–7·5 mm. The thickness of the lens therefore varies from 4 to 4·6 mm. The distance from the posterior surface of the lens (Knapp) to the retina is about 14 mm. The total length of the optic axis is 22·0 mm. The index of refraction is for the cornea 1·377, for the lens 1·45, vitreous humour 1·3366, and for the aqueous 1·377. In order that the course of a ray of light may be followed in any system of refractive media, it is necessary that the position of the five cardinal points should be known—namely, that of the *two principal points*, which are the points where the principal refracting surfaces are cut by the axis; that of the *two nodal points*, or those points in the refractive media to which a ray of

Monniki ("Tonometers en Tonometrie," Inaug. Dissert., Abst. in "Syd. Soc. Year Book," 1871–72, p. 339) ascertained that the tension of the eye varied within rather wide limits. It is normal when a pressure of 150–225 grains produces a depression of ¼ of a millimeter.

* "De l'Hemianopsie," 1880, p. 15.

† See also Munk, "Verhand. d. Phys. Gesells. zu Berlin," Sitzng. 4 July, 1879.

‡ "Centralblatt f. prakt. Heilkunde," Band iv. 1880, p. 40.

light is directed before, and appears to proceed from, after its refraction; and lastly, of the *focal*, or rather of the *two focal points*, one behind the lens and the other in front of the cornea. The relative positions of these cardinal points are as follows:—

1. Principal point, 2·1746 mm. behind the anterior surface of the cornea.
2. Principal point, 2·5724 „ „ „ „ „
1. Nodal point, 0·7850 „ in front of the posterior surface of the lens.
2. Nodal point, 0·3602 „ „ „ „ „
2. Focal point, 14·6470 „ behind „ „ „
1. Focal point, 12·8326 „ in front of the anterior corneal surface.

The two principal points thus lie at 0·4 mm. distance from one another, nearly in the middle of the anterior chamber of the eye. The two nodal points, also about 0·4 mm. from each other in the posterior part of lens; the second focal point for parallel rays close to or in the retina. The two nodal points lie so close to one another that they may be regarded as single, and visual rays passing through them as rectilinear. In like manner, the two principal surfaces may be regarded as marked in the spherical surface *h h*, which represents the refractive surface of the eye. Every point of a retinal image corresponds to a point of the object; and if it be desired to determine which are the corresponding points of the object and of the image, it is only requisite to join them by a line passing through the united nodal point. The retinal images are consequently inverted.

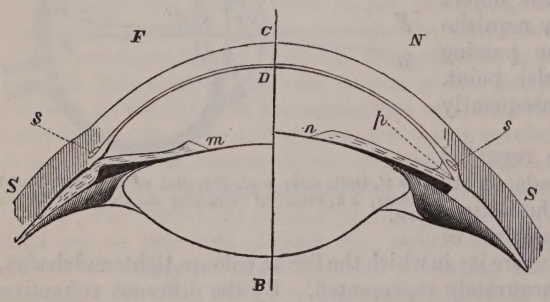
567. The Eye may be regarded as an optical instrument adapted to produce, on the surface of the Retina, a complete image or picture of luminous objects brought before it; in which the forms, colours, lights and shades, &c., of objects are all accurately represented. By the different refractive powers of the transparent media through which the rays of light pass, and by the curvatures given to their respective surfaces, both the Spherical and Chromatic aberrations are corrected in a degree sufficient for all practical purposes; so that, in a well-formed eye, the picture is quite free from haziness and from false colours. The power by which the eye adapts itself to variations in the distance of the object,—so as to form a distinct image of it, whether it be six inches, six yards, or six miles off,—is extremely remarkable, and has only recently been completely explained. It is obvious that, if we fix upon any distance such as that for which the eye is naturally adjusted (say 12 or 14 inches, the distance at which we ordinarily read), the rays proceeding from an object placed nearer to the eye than this would not be brought to a focus upon the retina, but would converge towards a point behind it; whilst, on the contrary, the rays from an object at a greater distance would meet before they reach the retina, and after crossing would have again diverged from each other when they impinge upon it; so that, in either case, vision would be indistinct. Now, two methods of adaptation suggest themselves to the Optician. Either he may vary the distance between the refracting surface and the screen on which the image is formed, in such a manner that the latter shall always be in the focus of the converging rays;

or, the distance of the screen remaining the same, he may vary the convexity of his lens, in such a manner as to adapt it to the distance of the object.* It has been thought that a change in the position of the retina might be effected by the recti muscles pressing upon the globe, and thus rendering its antero-posterior axis longer; but the power of accommodation may still be preserved when these muscles are paralyzed, whilst the entire loss of the power of adapting the Eye for different distances, which is experienced after the removal of the crystalline lens in the operation for cataract, or in cases of the congenital absence of this body, shows that some change in its place or figure is the principal means whereby the ordinary adaptation is effected. The precise changes which occur in the interior of the Eye when it is accommodated for viewing near objects, or during *positive accommodation*, have been determined by Helmholtz† with an instrument that he has termed an Ophthalmometer, the principle of which consists in examining the reflexion from the various ocular media of two flames:—alterations in the relative position and figure of which can be readily perceived and measured and furnish the data for the requisite calculations. By this means it has been ascertained that the essential alteration in the lens is a change effected in its figure by a muscular effort under the influence of the third nerve which increases its thickness in the antero-posterior diameter, the convexity of the anterior surface in particular undergoing a considerable augmentation (*n*, Fig. 260), and advancing towards the cornea; whilst the convexity of the posterior surface is but slightly augmented, and undergoes scarcely any change of place. The other and clearly secondary changes which have been observed are a contraction of the circular fibres of the Iris, making the pupil smaller—the pupillary edge of the Iris at the same time moving forwards, and the attached or peripheral edge (*p*) backward. The forward movement of the plane of the Iris amounts, according to Knapp,‡ to about 1-12th of an inch. Lastly, according to Becker,§ the points of the ciliary processes retire from the edge of the lens. The return of the lens to

Fig. 260.



C, Cornea; S, Sclerotic; F C N, Vertical plane of the Cornea; B C D, Axis of the Eye; *s s*, Canal of Schlemm; *p*, Angle formed by the Iris and Cornea, or margin of anterior Chamber; *m*, Position of Iris, and curvature of Lens in an Eye converged for parallel rays, distant vision, or negative accommodation; *n*, Position of Iris, and curvature of lens required for near objects, or for positive accommodation.

* According to the calculations of Olbers, based on the ascertained refractive powers of the media of the eye, the difference between the focal distances of the images of two objects, the one so far off that its rays are parallel, and the other at the distance of only four inches from the eye, is about 0·143, or one-seventh of an inch; but as the usual range of distinct vision does not extend to objects brought within six or seven inches, the amount of change required in the relative places of the refracting bodies and the retina would not ordinarily exceed a line.

† A full confirmation of Helmholtz's statement, with a good historical *résumé* of the whole subject, will be found in Gräfe and Sämesch's "Handbuch der gesammten Augenheilkunde," 1874–75. ‡ "Archiv f. Ophthalmol.," Band vi. Abtheil. ii. p. 1.

§ See his interesting Paper in Braun, Duchek, and Schlager's "Medizin. Jahrb.," 1864, p. 1. Coccius, in "Der Mechanismus des Menschlich. Auges," Leipzig, 1868, on the other hand, states that in accommodation for near objects as observed in eyes that have been operated on for iridectomy, the ciliary processes advance and swell up.

its original figure, after the cessation of the effort by which it has been accommodated for the distinct vision of near objects, is effected by the relaxation of the ciliary muscle, which permits the elasticity of the suspensory ligament to come into play. Under these circumstances the lens (*m*) becomes flattened, the peripheral margin of the iris is brought forward, the pupil dilates under the influence of the dilatator pupillæ, which is innervated by the Sympathetic nerve, the tips of the ciliary processes are approximated to the margin of the lens, and the so-called *negative accommodation* is effected. The main instrument in effecting these changes in the Eye appears to be the *Ciliary Muscle*, the structure and attachments of which were first clearly described by Mr. Bowman. It consists of unstriped muscular fibre, partly arranged in a circular manner, the innermost fibres (sometimes termed Müller's muscle) running parallel to the margin of the Cornea (*d*, Fig. 261), and partly dis-

Fig. 261.

posed radially (*a*), the fibres of the latter portion of the muscle appearing to be connected at their origin with the posterior elastic lamina of the Cornea, and externally or posteriorly being partly inserted into the Iris, forming the pillars of the Iris (Ligamentum pectinatum iridis), partly into the Sclerotic bounding the canal of Schlemm (*s*, Fig. 260), and partly and chiefly into that part of the outer surface of the choroid tunic, which corresponds to the ciliary processes. The movement which effects the change of form of the crystalline lens is performed in obedience to Volition, and is guided by sensation; yet we are not conscious of performing it, all that we *will* being the *result*: and thus we have another apposite illustration of the really automatic nature of what are termed 'voluntary movements' generally. The reasons for believing that the Eye, or rather the ciliary muscle, is passive in accommodation for distance are—the absence of any feeling of effort in persistently looking at a distant object, whilst a sense of effort and fatigue are soon experienced in looking at objects closely approximated to the Eye; the fact that the Eyes, on being opened after long closure, are adapted for distance; the impairment or absolute loss of the power of the accommodation in cases of paralysis of the Third nerve, by which the ciliary muscle is innervated, or when the muscle has been paralysed by Atropine. The object fulfilled by the contraction of the pupil in adaptation of the Eye for near objects, is evidently to exclude the outer rays of the cone or pencil, which, from the large angle of their divergence, would fall so obliquely on the convex surface of the eye as to be much affected by the spherical aberration, and thus to allow the central rays only to enter the eye, so as to secure the sharp definition of the

image; the principle being exactly the same as that on which the optician applies a *stop* behind his lenses, which reduces their aperture in proportion to the shortness of their focal distance. The channel through which this action is effected is evidently the same as that through which the convergence of the eyes is produced—namely, the inferior branch of the Third pair of nerves; to the action of which, the sensations received through the retina seem to afford the immediate stimulus, in the same manner as they do to the ordinary variation in the diameter of the pupil under the influence of light; but the voluntary determination to fix the vision upon the object is the original source of the action. That the presence of the Iris is not indispensable for the performance of positive accommodation is shown by the fact that, in a patient from whom Gräfe removed the whole Iris, this faculty remained perfect; and a similar power has been observed to exist in cases of congenital absence of the Iris.* The time occupied in accommodating the Eye for near objects is greater than that required for adapting it to view distant objects. According to Aeby the period occupied in changing the accommodation from 17 to $4\frac{1}{2}$ inches is about 2 seconds, whilst in changing it from $4\frac{1}{2}$ to 17 inches only 1·2 seconds are required. Vierordt, however,† states that he was able to effect the accommodation from 60 feet to $4\frac{1}{2}$ inches in about nine-tenths of a second, and from $4\frac{1}{2}$ inches to 60 feet in about seven-tenths of a second. Differences in age, and in amount of practice, are probably the chief causes of such variations in the results of different observers; accommodation for near objects being always accomplished more slowly with the advance of years. The adaptation of the Iris for variations in the intensity of light is still slower.—In healthy, or, as Donders terms them, 'emmetropic' eyes, the limits of clear vision lie between two points, the 'near-point' and the 'far-point.' The former, very near the eye in infancy, gradually recedes with advancing age; and Fellenberg‡ has shown, that at 10 years of age it is $2\frac{2}{3}$ inches distant from the front of the cornea; at 20 years of age, $3\frac{5}{9}$ in.; at 30, $4\frac{4}{5}$ in.; at 40, $6\frac{6}{7}$ in.; at 50, 12 in.; at 60, 24 in.; and at 70, 144 inches. The 'far-point' for healthy eyes is infinite distance, or, in other words, the refractive media of healthy eyes in a condition of repose are adapted to bring parallel rays to a focus on the retina. The field, or extent of the range of vision for each eye is very considerable.§ Measured from the optic papilla as a centre, it was found by Förster to be upwards 45°, downwards 65°, outwards 70°, and inwards 60°.

* See Dr. Soelberg Wells' instructive paper 'On the Paralysis of the Muscles of the Eye,' in the "Ophthalmic Hospital Reports," vol. ii. 1859–1860, p. 199.

† Henle and Meissner's "Bericht," 1857, p. 547.

‡ Canstatt's "Jahresbericht" for 1862, p. 157.

§ Landolt ('Il perimetro e la sua applicazione,' Quaglino's "Annal. d'Ottalmologia," Gennajo, 1872) gives rather higher numbers—viz., 135° for the horizontal and 120° for the vertical arc; and Uschakoff (Reichert and Du Bois-Reymond, "Archiv," 1870, p. 454) and Reich (Gräfe and Sämesch, "Handb. der Augenheilkunde," Band iii. 1874, p. 59) higher still—namely, in the horizontal meridian, max. 142°, min. 137°; and in the vertical, max. 120°, min. 114°. The field of vision is smaller in myopes and rather larger in hypermetropes than in healthy or emmetropic eyes. Helmholtz gives as average numbers derived from his observations the following values to the varying optical constant and cardinal points. The numbers, where not otherwise expressed, represent the distance from the anterior surface of the cornea in millimetres:—

	In accomodation For distance.	For near objects.
Radius of curvature of cornea	8	8
Radius of curvature of anterior surface of lens	10	6
Radius of curvature of posterior surface of lens	6	5·5
Situation of anterior surface of lens	3·6	3·2
„ of posterior	7·2	7·2
Focal distance of lens	43·707	33·785

Landolt found it to be upwards 55°, downwards 65°, outwards 85°, and inwards 50°.* The blind spot corresponding to the entrance of the optic nerve extends from 12°–18° along the horizontal plane of the retina. The actual rotation of the globe, or as Schuurman† terms it, the mean excursion of a healthy or emmetropic eye from the central point is inwards 45°, outwards 42°, upwards 34°, and downwards 57°.

568. When both eyes are fixed upon an object, their axes converge so as to meet in it; and the degree of convergence is of course altered by variations in the distance of the object; since, when the object is very remote, the optic axes are virtually parallel, whilst its approach causes them to incline towards each other, and this the more rapidly as the object is brought nearer, the increase being the greatest when it has arrived within the ordinary distance of distinct vision. Here, again, we have an example of the automatic nature of voluntary actions; for the convergence of the eyes that may be produced by this gradual approximation of an object on which the eyes are kept fixed by an exercise of the Will, far exceeds that which most individuals can induce by an effort made directly for the purpose; and if, when an object has thus been gradually approximated to within a few inches of the nose, the voluntary fixation be intermitted, and the optic axes be allowed to regain their parallelism, they can seldom be brought to converge again upon it, without repeating the whole process.—It has been thought, from the close accordance between the changes required for the adaptation of the eyes to distinct vision at different distances, and the alterations in the direction of the optic axes which are required to bring the two eyes to bear upon objects at varying degrees of proximity or remoteness, that the former of these movements is in some degree dependent upon the latter, or, at any rate, that the two proceed from a common motor impulse. But that the convergence of the axes is not itself in any way the occasion of the alteration of the focus of the eye, is shown by these two facts; first, that the adaptation is as perfect in a person who only possesses or uses one eye, as it is when both are employed; and second, that some persons possess the power of altering the focus of the eyes by an effort of the will, whilst the convergence remains the same.

569. The ordinary forms of defective vision, which are known under the names of *Myopia* and *Hypermetropia*, or 'short-sightedness' and 'long-sightedness,' are entirely attributable to defects in the optical adaptation of the eye. As already stated, the healthy, or *emmetropic* Eye, when at perfect rest is adapted to focus parallel rays on the retina (A, Fig. 262). If, however, a near object be looked at, since the rays proceeding from it are divergent, it is obvious that without some change in the media the image, instead of being focussed on the retina, would be focussed behind it. The Eye, by its power of accommodation, due to the action of the ciliary muscle in causing the lens to become thicker, is capable of effecting this alteration; and it is by an effort that increases with the proximity of the object that all near objects

are seen. In Hypermetropia (c), or long-sightedness, either the Eye as a whole is flattened from before backwards, or the lens is too flat, or both conditions may be present together. In either case, even *parallel* rays are not brought to a focus on the retina, much less divergent rays, such as those coming from near objects. It requires, in fact, muscular effort to bring parallel rays to a focus on the retina, and a very great effort, which cannot long be maintained, to bring divergent rays. The patient consequently complains of pain after a few minutes' reading or writing. To remedy this state, the eyes are placed in a passive state by the instillation of atropia; the strongest glass is then given, which produces distinct vision of distant objects (objects at 20 feet or more), or, in other words, which will focus parallel rays on the retina. In Myopia (D) either the Eye is too long in the antero-posterior direction, or the lens is too thick, or both conditions concur, and parallel rays, striking the cornea, are brought to a focus in front of the retina, and, after decussating, form a circle of dispersion on this membrane. All distant objects, therefore, are seen obscurely. On the other hand, the patient can see objects close to his eye, because the rays are there highly divergent. This condition may be remedied by placing a concave lens in front of the eye, which causes the rays of light to become divergent, and they are not therefore brought to a focus so soon in the interior of the eye. An interesting experiment, capable of a practical application in determining whether a given eye is normal or ametropic, and whether the ametropia is myopic or hypermetropic, is that known as Scheiner's experiment (Fig. 264); in this, a card or thin piece of metal, perforated with two small holes, the distance between which must be less than the diameter of the pupil, is placed before the eye. If the eyes be n ormal, two circles of light will be seen, which overlap one another to a cert ain extent, and in this brighter part all objects appear single, because the rays are united upon the retina at *c*. If, however, the axis of the eye be too long, as in Myopia, and the retina be at *p q*, the rays will have crossed, and double im ages will be seen in the central part of the field of vision; whilst if

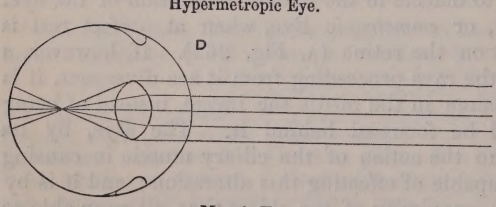
Hypermetropic Eye.



Myopic Eye.

the axis of the eye be too short, as in Hypermetropia, the rays will not have united, and double images will also be seen. By placing a piece of red or green glass over one of the holes, as at *g*, it is easy to determine whether the ray passing through that hole has or has not crossed* The term 'presbyopia,' as limited by Donders, simply expresses a deficient power of accommodation in the eye, resulting from increased density of the lens, or from defective power of the ciliary muscle, so that the 'near point' recedes beyond a certain point, arbitrarily fixed by Donders for the sake of convenience at eight inches. The effects of Atropine of Duboisia upon the eye are very remarkable, not only in dilating the pupil to the utmost in the course of from twenty to twenty-five minutes, but in completely paralyzing the ciliary muscle, and with it the power of accommodation, so that the 'near point' becomes gradually more and more distant, till at length it coincides with the 'far point.' Eserine, the active principle of the Calabar bean, on the contrary, causes extreme contraction of the pupil in the course of a few minutes, the 'far point,' and in many eyes the 'near point' also, becoming approximated to the eye, though the power of accommodation is never altogether lost. Both of these agents appear to exert a stimulating as well as a paralyzing influence on the nerves supplied to the Iris; atropine paralyzing the third and exciting the sympathetic nerve, whilst the Calabar bean paralyzes the sympathetic and excites the third.† The term *Astigmatism*‡ (*a*, privative, and *στίγμα*, a point) has been applied by Professor Whewell to a condition of the eye (first observed in himself by Professor Airy) in which there is an inequality in the refractive power (owing to difference in the degree of curvature either of the cornea, or of the lens, or of both) between the horizontal and vertical meridians of the eye. There is a consequent incapacity on the part of the eye to collect all the rays of light entering it to one exact focus; this has been shown by Donders to be of common occurrence in those who are otherwise healthy. A very slight degree of astigmatism is indeed natural since the cornea has been shown to be the top segment of an ellipsoid with three unequal axes. The asymmetry in disease is usually of such a nature that with each degree of accommodation horizontal lines are seen distinctly at a point nearer to the eye than vertical lines, showing that the vertical meridian has a shorter focal distance than the horizontal. This condition may be remedied by the use of the so-called cylindrical glasses. Many other interesting inquiries, respecting the action of the eye as an optical instrument, suggest themselves to the Physical philosopher; but the foregoing are the chief in which the Physiologist is concerned; and we shall now proceed, therefore, to consider the share which the nervous apparatus performs in the phenomena of vision.

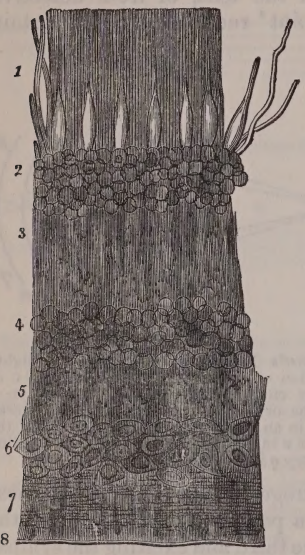
570. The Optic Nerve,* at its entrance into the eye, divides itself into numerous small fasciculi of ultimate fibrils; and these appear to spread themselves out, and to inosculate with each other by an exchange of fibrils, so as to form a net-like plexus which constitutes the inner layer of the Retina (Fig. 265, 7) in immediate contact with the 'limitary membrane' (8). There is considerable difficulty, however, in the precise determination of the course of the nerve-fibres in the Retina, on account of their minute size, their softness, and the alteration in their characters that takes place during mounting. Although uniformly much smaller than ordinary nerve-fibres, they present considerable diversities in size, the largest of them being only about 1-6000th of an inch in diameter, whilst the smallest are no more than from 1-30,000th to 1-50,000th of an inch. It is considered by Mr. Bowman that, like the fibres of the Olfactory nerves (§ 560), they consist of axis-cylinders without sheaths. They do not form a continuous layer at the yellow spot. Externally to the stratum of nerve-fibres, which may be called the Optic layer, is a vesicular stratum, called the ganglionic layer (Fig. 266, 3), which consists of a finely-granular matrix, wherein are imbedded nerve-cells resembling those of the nerve centres, and having, like them, one, two, or a variable number of processes, some of which appear to become continuous with the fibres about to be described; at the macula lutea all the ganglion cells are bipolar.

Fig. 265.



Vertical Section of *Retina* of the Human Eye:—1, bacillar layer; 2, outer granular layer; 3, intermediate fibrous layer; 4, inner granular layer; 5, finely-granular grey layer; 6, layer of nerve-cells; 7, layer of fibres of optic nerve; 8, limitary membrane.

It is to these fibrous and vesicular layers of the Retina, which together make-up the analogue of the cortical substance of the Cerebrum, that the principal supply of blood is distributed, by the minute capillary network which is spread-out through their substance. Immediately external to the ganglionic layer is the internal molecular layer (4) or the layer of grey vesicular matter of Mr. Bowman, the peculiar appearance of which is due to the admixture of a very fine plexus of spongy connective tissue given off from certain radially running supporting fibres, with nerve-fibrils of immeasurable minuteness. This again is succeeded by the layer of inner granules (5), which contains two distinct kinds of nucleated cellular elements, one of which is imbedded in radially arranged nerve-fibres, and the other in similarly disposed fibres of connective tissue; next comes (6), the external molecular or granulated layer, consisting of a thin layer of fine plexiform tissue, enclosing a few nuclei and smooth cells, with coarser fibres running parallel to the surface of the retina. The external granule layer (7), which consists of a thin layer of granules, lying in a finely striated matrix of connective tissue, in which extraordinarily fine fibrils are imbedded, running obliquely or parallel to the surface of the retina, and attached to the peripheric processes of the internal

* An excellent account of the historical development of our knowledge of the structure of the retina, from the year 1856 to the year 1868, is given by Krauss, in "Robin's Journal," Band vi. 1869, p. 438.

granules, and to the fibres of the rods and cones; and finally the layer of rods and cones (9), often also called the bacillary layer, or after its discoverer, Jacob's membrane. The rods are cylindrical bodies, with a length at the back of the Eye in Man of fifty to sixty micro-millimeters, and a diameter of two micro-millimeters, but becoming shorter anteriorly. Distributed at regular intervals between the rods, except at the macula lutea and ora serrata, are the flask-shaped cones. The distance between two cones amounts on an average to eight or ten micro-millimeters, the intervening space being occupied by three or four rods in a straight line, but in the region of the fovea centralis the distance is much less. In both structures two essentially different segments are distinguishable. (See Fig. 267.) The distinction is most marked in the cones, in which the outer segment is conical and highly refractile, whilst in the rods the segment is usually regularly cylindrical. The plane of junction of the two segments is more anterior in the cones than in the rods. After removal from the body the outer segments of both the rods and cones undergo a kind of coagulation, imbibe water, yield myelin drops, and break up into a series of disks, or become distorted. When well preserved they exhibit a longitudinal and very fine striation. Ritter, and others, think that an axial fibre can be seen in the *outer* segment of the rods. The internal segments of both rods and cones exhibit a fine longitudinal striation on their surface, which are rather channellings or fibres, probably the latter, since they both surround the base of the inner segment, and protrude from its outer extremity, enclosing the base of the outer segment in a kind of cradle. Hensen and some others believe that an axial fibre may be seen in the *internal* segment of the rods in some animals, but such fibres are not visible in man. The nucleated cone granule is a bipolar cell, the peripheric process of which is the cone itself, whilst the central extremity arises from the external molecular layer, by the coalescence of a number of fine fibrils. The rods and cones, the latter of which present in many animals, as in birds and reptiles, a drop of brilliant-coloured oily substance at their peripheric extremities, are the terminal organs of the optic nerve-fibres; but it still remains undecided whether the fibrils in the interior of the inner segment stand in connection with the nerve-fibrils of the fibres in question. The outer segment may possibly represent a non-nervous physical accessory apparatus. It is remarkable that section of the optic nerve in the living animal is followed by degeneration of all the elements of the retina except the bacillary layer, which thus scarcely seems to belong to the true nerve tissues. The layer of hexagonal pigment cells, commonly termed the pigment epithelium of the choroid, belongs both physiologically and morphologically to the retina. The outer segments of the rods and cones are so closely embraced by them, in well-preserved specimens, that they will rather separate from the internal segments or fracture through their substance than become detached from

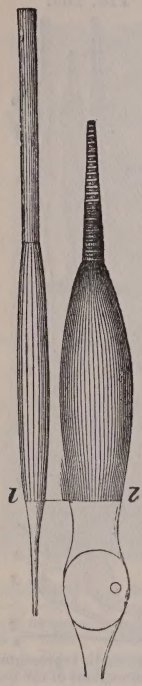
them. The proper nervous structures of the retina are permeated and supported by a stroma of connective tissue, which is bounded externally and internally by the membranæ limitantes, the external limiting membrane corresponding to the inner extremity of the rods and cones or line of detachment of Jacob's membrane; and the internal limiting membrane (8, Fig. 265) resting on the hyaloid. The *supporting connective tissue* (Fig. 268) is closely allied structurally to that of the brain and spinal cord, which has been named Neuroglia by Virchow. By Schultze it is termed spongy connective tissue. It fills up the interspaces between the ganglion cells, granules, and nerve-fibres, and consists of radial supporting fibres (most constantly found in the internal granule layer) and oval homogeneous nuclei.

Fig. 267.



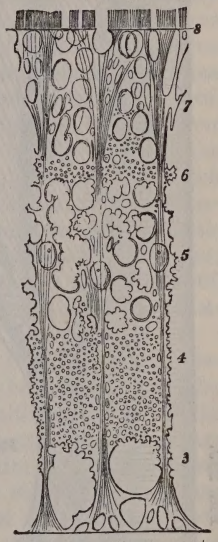
Rod and cone from the Retina of Man preserved in a two per cent. solution of perosmic acid, to show the fine fibres of the surface, and the different lengths of the internal segment. The outer segment of the cone is broken up into disks, which, however, are still adherent to one another; at the base of the cone are seen a few fine hairs; *l*, limiting membrane (×1000 diam.).

571. *Vision or Visual Purple. Rhodopsin.*—The outer segment of the rods of the retina is characterized by the presence of colouring matter, which from its tint is termed "visual purple," or Rhodopsin. It appears to be very generally present, Kühne having only noticed its absence in the Bat, in some Birds, and in Reptiles. The outer segments of the cones are uncoloured; and in the case of the rods, it is remarkable that the colour is absent in those that are near the fovea centralis and in those which are near the ora serrata. The colouring matter is developed before birth. It dissolves readily in a solution of the biliary acids, and especially in purified colourless ox-bile. The solution on exposure to light rapidly bleaches, changing from carmine to red and yellow (chamois), and then becoming colourless and transparent as water. Under spectroscopic examination, visual purple is found to absorb all the rays of the spectrum, from the yellow-green to the violet; whilst it allows a little violet, much of the yellow, and all the orange and red to traverse it. A rosy retina becomes quite pale in the course of fifteen minutes when exposed to the yellow-green portion of the spectrum; more slowly in the blue-green, blue, indigo, and violet; whilst it scarcely undergoes any change in the red and ultra violet. The colour fades even in the living animal on exposure to light, and with rapidity proportionate to the intensity of the light; hence, the rosiest retinæ are obtained from animals which have been kept for some time in the dark, and in order to preserve the colour for experimental purposes, it is requisite to perform all requisite manifestations by the monochromatic sodium light. Other agents which rapidly induce bleaching of the colour are—almost all acids, ether, alcohol, chloroform, turpentine, chlorine, iodine, and bromine. A temperature of 76° C. (169° F.) destroys the colour of the retina of the frog

* The existence of this colouring matter was known as long ago as 1839, when it was noticed by Krohn in the eyes of Cephalopods. Leydig and Schultze subsequently found that the eyes of Arthropods also possessed a rose-coloured pigment. In 1851, H. Müller stated that the rods of the retina of the frog were red, and his observations have been corroborated by Leydig, Boll, and Kühne. See the "Photo-chemistry" of Kühne, translated by Mrs. Foster, 1878; and Kühne's article on the "Chemistry of the Retina," in Hermann's "Handbuch der Physiologie 'Der Sinnesorgane,'" p. 259.

almost instantaneously; of 65° C. (149° F.) in half an hour; whilst at 50° C. (122° F.) it long remains unaltered. It is not acted on by ammonia, common salt, alum, iron and zinc sulphate, ozone, oils, urea, or by trypsin digestion. Alum acts as a mordant, and prevents the colour from undergoing further change by the action of light. By throwing upon the retina of an animal that has been for some time kept in the dark the well-defined image of a brightly illuminated object for a short period, the part on which the light falls is bleached, whilst the remaining portion retains its colour; and when this is fixed by a solution of alum, an "*optogram*" may be obtained, in which the details of the illuminated object may be recognized. It would appear from this that during life the retinæ, when exposed to light, are constantly being bleached, the colouring matter undergoing a constant renewal; but the absence of the rhodopsin in the neighbourhood of the fovea centralis, which is the most sensitive part of the Eye for form, size, and colour, forbids the supposition that it is of great importance in ordinary visual perception. The *internal* segments of the cones of birds and reptiles contain coloured fat globules, and Kühne has applied the term "chromophane" to the colouring matter they contain.

Fig. 268.



Diagrammatic representation of the connective tissue of the retina as seen near the ora serrata. The numbers correspond to those of the several layers of the retina given on p. 729.

572. It has been observed that the retinæ of frogs which have been exposed to the light separate with more difficulty from the choroid than those of frogs which have been kept in the dark, whilst at the same time the pigmented epithelial layer is more strongly adherent to the rods. This difference in the relations of the retina* has been shown to be due to a change in the position of the pigment, or "Fuscin needles" of Kühne, and to a movement of the protoplasm. In the eyes of frogs retained in the dark, the pigment is concentrated in the body of the cell, a small quantity only lying between the rods and extending for about one-third the length of the outer limbs. But after exposure to light, the pigment is found to a very large extent arranged in strata between the rods. Hence it would appear that light acts as a stimulus to the cells of the retinal epithelium, which are excited by it to throw out pseudopodic processes, which pass down between the outer limbs of the rods. In darkness the processes are retracted. Red light appears to act as a still more powerful stimulus than white. The adhesion of the epithelium to the rods is augmented by a low temperature, whilst it is diminished by the action of curare. The effect of the phototropic stimulation of the retina has been carefully worked out by Kühne.

573. There are two spots in the Retina in which the arrangement of the foregoing components is essentially different from the rest, and from these differences important physiological conclusions may be drawn. One of these is the slight eminence at which the Optic nerve enters, which is a little below and internal-to the posterior extremity of the axis of the eye. The other is the 'yellow spot of Soemmering,' which is situated in the exact centre of the retina. The modifications undergone by the Retina at the macula lutea

* See Boll, "Monatsbericht d. Berlin Acad.," January and February, 1877; Czerny, "Sitzs.-ber. der Wien. Acad.," Band lvi.; and Kühne in Hermann's "Handbuch der Physiologie," Band vii. 1879, p. 333.

and fovea centralis are considerable. Nearly in the axis of vision an intensely yellow pigment is deposited between the elements of the different layers, with the exception of the bacillar and external granular layer. The centre of the yellow spot is depressed anteriorly (Fig. 269) to form the fovea centralis. The retina is thicker at the macula lutea, of course excepting at the fovea centralis, than in the adjoining parts, and is at the same time softer and more prone to post-mortem change, probably in consequence of the deficiency of the radial supporting connective tissue. The layer of the ganglion cells and internal division of the external granule layer, are the layers that are most obviously thickened. On the other hand, there is no continuous layer of nerve-fibres beneath the membrane limitans interna. The rods are altogether deficient, their place being taken by the cones, which become longer and narrower, and are closely packed, about 135 being contained in the 1-100th part of a square millimeter. The course pursued by the cone-fibres changes as compared with other parts of the retina from a radial to a horizontal direction. At the fovea all the layers of the retina, with the exception of the cones and external granules, diminish to a minimum. Krause estimates the number of the fibres in the optic nerves at one million, the number of the cones at seven millions, and of the rods at 130 millions.* More re-

* Krause, "Allgem. u. Mic. Anat.," 1876.

cently Salzer* finds the number of optic nerve fibres to be 438,000, and of cones 3,360,000, or from seven to eight cones for each nerve-fibre.† And hence it seems unequivocally to follow, that visual impressions cannot act primarily upon the nerve-fibres ;—a conclusion which harmonizes with the fact, that the fibres of the optic nerve are superimposed upon each other in the stratum which they form, in such numbers that it is not conceivable that they should be the primary recipients of luminous impressions, since their transparency must allow rays of light to penetrate from one portion of the layer to another. The bacillary layer was formerly regarded as a reflecting apparatus, having for its purpose to stop the further passage of light, and to intensify its influence on the true retina; but since its connection with the proper nervous elements of the retina has been established, there seems much ground for believing (with Prof. Kölliker) that its rods and cones are the primary recipients of luminous impressions, and that they communicate their condition to the fibres of the optic nerve, by means of their own delicate fibrous prolongations, which seem to come into more or less direct connection with its ultimate ramifications. It is not a little remarkable, that the point of the entrance of the Optic nerve should be deficient in the power of receiving distinct visual impressions; whilst the "yellow spot," the position of which according to Landolt is 3·905 mm. to the outer side of the optic disc, and 0·785 mm. higher, is the most sensitive portion of the entire Retina.‡

574. *Eidoptometry.*—The *limits* of Human Vision, as regards the minuteness of the objects of which it can take cognizance, have been investigated by Professor Ehrenberg, with the view of calculating the ultimate power of the Microscope.§ In opposition to the generally received opinion, Ehrenberg arrived at the conclusion that, in regard to the extreme limits of vision, there is little difference amongst persons of ordinarily good sight, whatever may be the focal distance of their eyes. The smallest square magnitude usually visible to the naked eye, either of white particles on a black ground, or of black upon a white or light-coloured ground, is about the 1-405th of an inch. It is possible, by great condensation of light, and excitement of the attention, to recognize magnitudes between the 1-405th and 1-540th of an inch, but without sharpnesss or certainty. Bodies which are smaller than these cannot be discerned with the naked eye when single, but may be seen when

* Salzer, "Sitzungsb. d. k. Akad. d. Wiss. zu Wien.," Band lxxxi. 1880, January.

† Kuhnt, Gräfe's "Archiv f. Ophth.," 1879, gives a much lower number, estimating that at the choroidal ring the optic nerve only possesses from 31,400–40,000 fibres.

‡ Aubert and Förster (v. Gräfe's "Archiv f. Ophth.," Band vii. 1860, p. 152) have shown that the acuteness of vision in receding from the fovea centralis does not diminish in concentric circles, but more quickly above and below, and more gradually towards the out and the inside. They found also that the more remote any object was from the optic axis the larger it must be to be recognized, and further, that a small object in proximity to the eye can be recognized at a greater distance from the axis than a larger object remote from the eye. The measure of acuteness of vision in general use amongst ophthalmic surgeons is a series of letters, the thickness of which is one-fifth of their height, and which are placed at such a distance that they subtend an angle of 5′. The distance d at which such letters are still distinctly recognized divided by the distance D at which they subtend an angle of 5′ expresses the sharpness of vision. Thus, if the letters C, or G, or B, be made of such a size that at 20 feet they subtend an angle of 5′, and can be read at that distance, the vision of the experimenter is regarded as being perfect, $V = \frac{d}{D}$ or $\frac{20}{20} = 1$; but if he can only see them at 10 feet his vision $= \frac{10}{20} = \frac{1}{2}$; if only at 5 feet his $V = \frac{5}{20} = \frac{1}{4}$, and so on. The absolutely smallest visual angle at which any object can under exceptionally favourable circumstances be seen subtends an angle of 50″. (Hirschmann, 1867.)

§ Taylor's "Scientific Memoirs," vol. i. p. 576. See also Helmholtz, "Physiolog. Optik.," 1860.

placed in a row. The degree of illumination is of essential importance, since, if sufficiently bright, extremely small points can be recognized: thus gold dust, the particles of which do not exceed 1-1125th of an inch, may be discerned with the naked eye in common daylight, whilst many of the fixed stars have no appreciable visual angle. The delicacy of vision is far greater for *lines* than for mere points; since opaque threads of 1-4900th of an inch in diameter (about half the diameter of the silkworm's fibre) may be discerned with the naked eye, when held towards the light. The size of the retinal image in these cases must be exceedingly small. In some of Bergmann's experiments it was found that black and white chequers of 1-25th of an inch square could be discerned at such a distance that the retinal image of each square could not have exceeded half the diameter of one of the cones of the bacillary layer.* A difference of illumination amounting to 1-10th for all moderate degrees of light is recognizable by the retina. Thus the addition of one candle to ten, or of ten to one hundred candles, is perceived. The degree in which the *attention* is directed to them has a great influence on the readiness with which very minute objects can be perceived; and Ehrenberg remarks that there is much greater difference amongst individuals in this respect, than there is in regard to the absolute limits of vision. Many persons can distinctly see such objects, when their situation is exactly pointed out to them, who cannot otherwise distinguish them; and the same is the case with persons of acuter perception, with respect to objects at distances greater than those at which they can see most clearly. "I myself," says Ehrenberg, "cannot see 1,2700th of an inch, black or white, at twelve inches' distance; but having found it at four or five inches' distance, I can remove it to twelve inches, and still see the object plainly." Similar phenomena are well known in regard to a balloon or faint star in a clear sky, or a ship in the horizon: we can easily see them after they have been pointed out to us; but the faculty of readily descrying objects depends on the habit of using the eyes in search of them, and of attending to the sensory impressions thus received. Aubert† found that the excitability of the retina for extremely feeble stimuli rapidly attained a high degree when a dark room was entered, though a slight increase in sensitiveness continued to take place for a considerable period if the sojourn in it were protracted. A wire heated by electricity was first discovered when at a temperature of about 666° F. In another series of experiments he found that the feeblest illumination of the field of vision that could be recognized was about equal to that of the planet Venus when brightest, or to the white light of day admitted into a chamber through an opening forty-one seconds square. Small surfaces, however, always require considerably greater illumination, in order that they should be perceived, than large.

575. The amount of light admitted to the eye is regulated by the contraction and dilatation of the Pupil, the smallest diameter of which is about 1-20th, and its largest about 1-3rd of an inch. The arteries of the Iris are derived from the long ciliaries, and in part from the short ciliaries and the veins, whilst chiefly joining the venæ vorticosæ, and thus returning the blood they contain by the ophthalmic veins, discharge their contents in part also into the canal of Schlemm, and thus returns a portion of their blood by the facial vein. These vessels constitute the substance of the iris. A layer of somewhat inbricated oval epithelial cells, with round nuclei, covers the anterior surface in the infant, but is distinguishable with difficulty, or is only partially present, in the adult. Posteriorly is a distinct layer of pigment cells. The limits of these are so ill-defined as to have led some to describe

* Henle and Meissner's "Bericht," 1857, p. 559. † "Physiologie der Netzhaut," 1864.

them as forming a uniform sheet of protoplasm with pigment granules distributed through its substance. Owing to the presence of this pigment, the iris is absolutely opaque. The Iris is well supplied with nerves derived from the 3rd, 5th and sympathetic, most of the larger trunks lying in front of the blood-vessels.* They enter the Iris from the ciliary muscle, and form five circular concentric plexuses connected by radial fibres from which delicate primitive fibrils are given off, ending in a terminal network covering the whole of the iris. Formad was unable to discover any ganglionic cells. The muscular structure of the Human *Iris* is entirely of the non-striated kind, being composed of the elongated fibre-cells with staff-shaped nuclei which are characteristic of that variety. Part of these are so disposed as to form a circular sphincter (Fig. 270, *a*), which can be readily seen in the iris of the white rabbit, or in the blue iris of man from which the uvea has been removed, immediately surrounding the pupillary margin to the breadth of about one-third of a line. The fibres of this sphincter are not absolutely parallel, especially at the outer margin, where they seem to become continuous with those of the radiating fasciculi (*b b*), which may be traced from this sphincter (though usually with difficulty) to the outer margin of the iris, sometimes anastomising with each other in their course.† The contraction of the annular fibres, whereby the diameter of the pupil is *diminished*, is effected, as already explained, through the instrumentality of the Third pair of nerves; the contraction of the radiating fibres, on the other hand, whereby the pupil is *dilated*, is under the government of the cervical portion of the Sympathetic, being called forth‡ by irritation of the trunk of the Sympathetic in the neck, or of the lower part of the cervical portion of the Spinal cord, by the magneto-electric apparatus; whilst section of the Sympathetic produces a permanent contraction of the pupil, the action of the Third pair being then no longer antagonized. It appears, from other experiments, that the fibres through which this movement is effected, pass through the Gasserian ganglion, and are distributed to the eye by the ophthalmic branch of the Fifth pair. The contraction of the Pupil is thus a reflex action, induced by excitation of the retina, and acting through the nervous circle formed by the optic nerves and tracts, and the third pair of cerebral nerves. Whilst admitting that the movements of the Iris are essentially effected by muscular tissue, it must be acknowledged that its extreme vascularity renders

Fig. 270.

† See Prof. Kölliker's "Mikroskopische Anatomie," Band ii. § 272; and Jos. J. Lister's 'Observations on the Contractile Tissue of the Iris,' in "Quart. Journ. of Microscop. Science," vol. i. p. 8. See "Lancet," vol. i. 1870, pp. 127 and 211.

‡ See Budge and Waller, "Gazette Médicale," 1851, Nos. 41, 44; and Wagner, "Journ. de Physiologie," 1860; Franck, "Comptes Rendus," 1879, p. 1016.

it highly susceptible of either local or general changes in the pressure of the blood. Fabricius of Aquapendente likened the closure of the pupil to the turgescence of erectile tissue, and his opinion has been supported by such observers as Portal, Bichat, and Haller; but the activity this movement presents is too great to be thus explained; and it would seem that, whilst contraction of the pupil is mainly effected by the sphincter innervated by the Third, it may also be aided by vascular dilatation. Thus it may be caused by section of the sympathetic, or even by merely hanging the head down, by puncturing the Eye, and reducing the intra-ocular tension by allowing the escape of the aqueous, and it occurs in Iritis. On the other hand, the pupil is dilated in glaucoma, in which the intra-ocular tension is augmented; and it has been observed by Bernard* that contraction of the pupil can be easily induced after section of the Third nerve by paracentesis of the cornea, section of the sympathetic, and by eserine. It would hence appear that the movements of the pupil are in part the result of variations in the size of vessels which are governed by the sympathetic, and which there is reason to believe may be excited through the Fifth. The two pupils contract consentaneously, light falling on either retina causing the opposite Eye to contract. It is remarkable, also, that the stimulus of light applied to a perfectly blind Eye will cause the opposite pupil to contract. It answers the purpose, as we have seen, not merely of excluding superfluous light from the eye, but also of cutting off the most divergent rays when the object is brought near the refracting surface (§ 567), and of thus preventing the indistinctness of vision which would result from their admission. For although, when the Eye is at rest, parallel rays come to a focus on the Retina, divergent or convergent rays proceeding from any point come to a focus either behind or in front of that membrane, forming upon it what is termed a "circle of diffusion;" but by cutting off the outermost rays and permitting the entrance of those only which are nearly parallel, the magnitude of such circles is materially diminished, and vision correspondingly improved. It is interesting to observe that contraction of the pupil is effected with greater rapidity than dilatation, a matter of some importance in sudden alternations from light to darkness. The iris contracts and the pupil becomes smaller when light falls on the retina; when accommodation is made for near objects; when the eyes are made to converge; during sleep, under the action of certain medicinal agents, as eserine, nicotin, opium, and pilocarpin;† and in hyperæmic conditions of its vessels, the iris dilates, the pupil becoming larger in the absence of light; on powerful stimulation of sensory nerves during violent muscular effort in dyspnœa; in conditions leading to anæmia of the vessels of the Iris, in certain mental emotions, as fear; and as the result of the action of atropine, duboisia, and other drugs. M. Brown-Séquard‡ has shown that the Irides of various animals may be directly affected by Heat and Light. Thus, if the eyes of dogs, cats, or rabbits, either soon after death, or shortly after their removal from the body, be suddenly exposed to an alteration of temperature amounting to 50° or 60° F., if the pupil be contracted, it expands; though, on the contrary, if it be in the first instance dilated, it speedily contracts. These effects of heat have not been observed either in Man or the Mammalia during life. As regards the direct action of Light, Brown-Séquard found that the Irides of eels and frogs which had been removed for several (even sixteen) days from the body

‡ "Journal de la Physiologie," 1859, vol. ii. p. 294.

in winter, as well as the Irides of mammals and birds for a short time after death, contracted on exposure to the light of the sun or of a candle; this effect being produced even when the posterior half of the eye had been cut off, and when, therefore, there could have been no reflex action. The yellow rays appeared to have the greatest energy. These remarkable phenomena prove, at all events, that the contraction of the pupil is not, as has occasionally been maintained, exclusively due to vascular turgescence. The cause of the effect produced by Light is difficult to explain, but that occasioned by Heat may perhaps be attributed, as Brown-Séquard suggests, to the circumstance that a contracted muscle has less power than one in a state of extension, so that if a stimulus act equally on both, when previously nicely balanced in point of strength, the uncontracted muscle will exert the greater force, and consequently overpower the contracted muscle.

576. The sense of Vision depends, in the first place, on the excitement of our sensational consciousness by the ocular picture impressed upon the retina, which represents the outlines, lights and shades, colours, and relative positions of the objects before us; and all the ideas respecting the real forms, distances, &c., of bodies, which we found upon these data, are derived through the perceptions, either instinctively or experientially suggested by sensations. Many of these ideas are derived through the combination, in our minds, of the Visual perceptions, with those derived from the sense of Touch. Thus, to take a most simple illustration, the idea of *smoothness* is one essentially tactile; and yet it constantly occurs to us, on looking on a surface which reflects light in a particular manner. But if it were not for the association, which experience leads us to form, of the connection between *polish* as seen by the *eye*, and *smoothness* as felt by the *touch*, we should not be able to determine, as we now can do, the existence of both these qualities from an impression communicated to us through either sense singly.—The general fact that, in Man, the greater part of those notions of the external world, by which his actions in the adult state are guided, are acquired by the gradual association of the two sets of perceptions derived through the Sight and through the Touch, is substantiated by amply sufficient evidence; this being chiefly derived from observations made upon persons born blind, to whom sight has been communicated by an operation, at a period of life which enabled them to give an accurate description of their sensations. The case recorded by Cheselden is one of the most interesting of these. The youth (about twelve years of age), for some time after tolerably-distinct vision had been obtained, saw everything *flat* as in a picture, simply receiving the consciousness of the impression made upon his retina; and it was some time before he acquired the power of judging, by his sight, of the real forms and distances of the objects around him. An amusing anecdote recorded of him shows the complete want which there is in Man, of any natural or intuitive connection between the ideas formed through visual and through tactile sensations. He was well acquainted with a Dog and a Cat by *feeling*, but could not remember their respective characters when he *saw* them; and one day, when thus puzzled, he took up the Cat in his arms, and felt her attentively, so as to associate the two sets of ideas, and then setting her down, said, 'So, puss, I shall know you another time.'—A similar instance has come under the Author's own knowledge; but the subject of it was scarcely old enough to present phenomena so striking. One curious circumstance was remarked of him which fully confirms (if confirmation were wanting) the view here given. For some time after his sight was tolerably clear, the lad preferred finding his way through his father's house (to which he had been quite accustomed when blind)

by touch rather than by sight, the use of the latter sense appearing to perplex instead of assisting him; but, when learning a new locality, he employed his sight, and evidently perceived the increase of facility which he derived from it.*—The actions performed by many new-born animals do not constitute any valid objection to the view that such visual perceptions are for the most part *acquired* by Man; for all that is indicated by them is, that certain sensations give rise to movements adapted to supply the wants to which they relate; and they do not afford any proof that definite notions, such as we entertain, of the forms and properties of external objects are possessed by the animals which exhibit them.—We shall now examine, a little more in detail, into the means by which we gain such notions, and the data on which they are founded.

577. The first point to be determined is one which has been a fruitful source of discussion—the cause of *erect vision*, the picture upon the retina being inverted; and with this is connected the general question of the origin of our *Sense of Direction*.—The difficulty which has been raised in regard to the former subject is rather apparent than real; being founded on an erroneous notion of the nature of the Visual sense. For it seems to have been supposed that we *look at* the retinal picture with the 'mind's eye,' just as we look at the picture formed by a Camera with the bodily eye; and that our consciousness must be therefore impressed by its discordance with the information which we receive through our sense of Touch. Some philosophers, indeed, have actually gone so far as to assert that the Infant must at first see everything inverted, and that the erectness of visual objects is only learned by the corrective experience gained by touching and handling them. But such is clearly not the case; for the visual perception is obviously not a mere *transfer* of the sensorial impression, but is a *mental state excited by it*, and therefore related to it as an effect to its cause; and we know no reason why it should be *less natural* for the retinal picture to *suggest to the mind* the notion of *erect* position, than for it to have the contrary effect. Moreover, it will appear from investigations to be hereafter detailed (§ 594), that there is in the eye a 'common centre of direction,' through which all lines must pass, that are drawn from any points of an external object to the corresponding points of its retinal image;† and that we immediately refer the cause of the excitation of any spot of the retina by a luminous impression, to an objective source in the 'line of direction' which passes from that spot through the centre of direction; so that, in virtue of this 'law of visible direction,' as all the lines of direction cross each other both vertically and laterally, the formation of an inverted image upon our retina suggests to our minds the representation of the object in its erect position, and the same reversal takes place also in regard to its two sides, which are transposed in the retinal picture. A peculiar

* The question has been proposed, whether a person born blind, who was able by the sense of Touch to distinguish a cube from a sphere, would, on suddenly obtaining his Sight, be able to distinguish them by the latter sense. This question was answered by Locke in the negative; and, as appears from the facts above stated, with justice.

† With regard to the precise situation of this 'centre of direction,' there is a want of accordance among those who have attempted to determine it; some having placed it in the centre of the pupil, others in the centre of the crystalline lens, others at various distances between this and the centre of the globe, and others (among them Sir D. Brewster) *in* the centre of the globe. This last notion, with the 'law of visible direction' founded upon it—which affirms that every object is seen in the direction of the perpendicular (or radius) to every point of the retina which is impressed—is so manifestly wrong, that it is difficult to conceive how it could ever have been entertained by men of science. The experimental investigations of Listing indicate a point near the centre of the crystalline as the 'centre of direction' (§ 563).

arrangement of the receptive apparatus, which seems to be subservient to this mental appreciation of direction, has been already noticed.

578. The cause of *Single Vision with the Two Eyes* has, in like manner, been the subject of much discussion; and here, too, the difficulty is rather apparent than real, having for its foundation the idea that the mind looks at the two retinal pictures as at two separate objects, instead of being impressed by a certain state of the Sensorium, which may be excited through the instrumentality of either eye, or through that of both in combination. Some have even asserted, under the influence of this idea, that we do not really employ both eyes simultaneously, but that the mind is affected by the image communicated by one only; which might seem to be confirmed by the fact sufficiently well ascertained respecting the alternate use of the two eyes, when they are looking through two differently-coloured media. But of this assertion a complete disproof is afforded by the knowledge we now possess (§ 580), that our appreciation of the solid forms of bodies depends on the combination, *by the Mind*, of the images simultaneously suggested by the two pictures; and that our knowledge of distances is in great part obtained by like manner.—Attempts have been made to explain the phenomena of Single Vision by the peculiar decussation of the Optic Nerves formerly described; it being supposed that only one Optic Ganglion would be affected by an impression made upon both Retinæ.* This explanation, however, even supposing the fact to be as stated, would be far from affording the solution of the problem; and it would be entirely inapplicable to that very important series of phenomena to be next described, which show how large an amount of information we derive, not from the *repetition*, but from the *difference*, of the sensory impressions made by the same object upon our two retinæ; and which indicate that here, as in the case of erect vision, the *mental interpretation* of the sensory impressions is a process altogether removed from the simple affection of the consciousness by those impressions, and is not to be accounted for by any structural arrangements of the Sensorial apparatus. One condition of single Vision, however, seems to be this, that the two images of the object should be formed on parts of the two retinæ which are *accustomed* to act in concert; and *habit* appears to be the chief means by which this conformity is produced. There can be no doubt, however, that double images are continually being conveyed to the Sensorium; but that, from their want of force and distinctness, and from the attention being fixed on something else, we do not take cognizance of them. This may be shown by a very simple experiment. If two fingers be held up before the eyes, one in front of the other, and vision be directed to the more distant, so that it is seen singly, the nearer will appear double; while, if the nearer one be regarded more particularly, so as to appear single, the more distant will be seen double. A little consideration will show, therefore, that our minds must be thus continually affected with sensations, which cannot be united into the idea of a single image; since, whenever we

* This decussation seems to be, in some cases, more complete than in others, for in various experiments made by Dr. Waller upon the effects of section of one optic nerve, it was found that the *Optic Tract* upon the same side as the lesion, showed no signs of degeneration, whilst that of the opposite side soon underwent disorganization with the exception of a few strands on the inner and posterior aspect; thus countenancing the opinion that there are commissural fibres passing between the corpora quadrigemina of the two sides, but negativing the view that some of the fibres from each retina run to the corpora quadrigemina on their own side. Dr. Waller is inclined to think, therefore, that the decussation is complete. It is important to observe, that in these experiments the anterior portion of the divided nerve, with the retinal elements, remained unchanged for many weeks. See "Proceedings of the Royal Society," vol. viii. On the other hand, the reader may refer to some curious cases of partial Amaurosis recorded by Mr. Towne in the "Guy's Hospital Reports" for 1863, p. 127.

direct the axes of our eyes towards any object, almost everything else will be represented to us as double; but we do not ordinarily perceive this, from our minds being fixed upon a clear and distinct image, and disregarding, therefore, the vague undefined images formed by objects not in the visual focus. Of this it is very easy to satisfy one's-self. The above experiment, moreover, makes it evident that double vision cannot result from *want of symmetry* in the position of the images upon the retina, to which some have attributed it; for it answers equally well, if the line of the two fingers be precisely in front of the nose, so that the inclination of both eyes towards either object is equal; the position of the images of the second object must then be at the same distance on either side from the central line of the retina, and yet they are represented to the mind as double. Hence, too, it seems clear that singleness of vision in an object that is *looked-at*, is also dependent in part upon the *convergence of the optic axes* in that object (§ 568); and that this is the case appears further from a curious experiment devised by Prof. Wheatstone, in which two similar objects are made to seem as one, when they are placed in the line of convergence. This is accomplished by looking through two tubes, placed before the right and left eyes respectively, at two similar objects of any description, placed near the farther extremities of the tubes; if, now, these objects be slightly approximated, so that the axes of the tubes (still directed towards them) meet in a point beyond, the mind is impressed with the image of only a single object, and this appears to be removed back to the point of convergence. It has been found by Gehler, J. Müller, and others, that those objects which do not appear double when a given point is fixedly regarded, are situated in a certain circular line, termed the Horopter, of which the chord is formed by the distance between the eyes, whilst the magnitude of the circle is determined by three points—namely, by the two eyes and the point towards which their axes converge. Prof. Helmholtz, however, considers that generally the Horopter is a line of double curvature, produced by the intersection of two hyperboloids, or exceptionally, of two plane curves; and that when we look straight forward to a point of the horizon, the Horopter becomes a horizontal plane passing through our feet—being, in fact, the ground on which we are standing. The form and situation of the Horopter appear to be of great practical importance in enabling us to judge with accuracy of the shape and distance of those objects which are situate in it.*

579. On the mode in which our notion of the *solid forms* and *relative projection* of objects is acquired, great light has been thrown by the interesting experiments of Prof. Wheatstone.† It seems perfectly evident, both from reason and experience, that the flat picture upon the retina, which is the immediate source of our sensation, could not itself convey to our minds any

* See Müller's "Physiology," translated by Dr. Baly, vol. ii. p. 1196; also the Croonian Lecture for 1864, delivered before the Royal Society, by Professor Helmholtz, in vol. xiii. of the "Proceedings of the Royal Society," and Dr. H. Kaiser in "Archiv f. Ophth.," Band xv. 1869, p. 75. Dr. Kaiser, who has treated the subject analytically, states that the interior system of the Horopter is an hyperbole of equal dimensions for each eye; one of the radii of which passes through the fovea centralis and never passes through the punctum cæcum; its summit is found at the side of the fovea. The real axes have the same angle between them as that of the two retinal horizons, their inclination on this does not differ much from half a right angle. In individual cases it is found that for a point of fixation situated at an infinite distance, the Horopter becomes a spherical surface with an infinite radius. Thus in looking at a star all the stars are found on the Horopter. For a point of fixation situated in the primary position of the retinal plane, the Horopter becomes reduced to a circle, the circle of the Horopter of Müller passing through the centre of each globe and the fixed point. For a point of fixation situated in the median plane, the Horopter is an ellipse situated in a plane which bisects the angle formed by the visual plane and the primary position.

† "Philosophical Transactions," 1838 and 1852.

notion but that of a corresponding plane surface. In fact, any notion of *solidity*, which might be formed by a person who had never had the use of more than one eye, would entirely depend upon the combination of his visual and tactile sensations. This view is fully confirmed by the case already referred to (§ 576), as recorded by Cheselden. The first visual idea entertained by the youth was, that the objects around him formed a flat surface, which touched his eyes, as they had previously been in contact with his hands; and after this notion had been corrected, through the education of his sight by his touch, he fell into the converse error of supposing that a picture, which was shown to him, was the object itself represented in relief on a small scale.—But where both eyes are employed, it has been ascertained by Prof. Wheatstone, that they concur in exciting the perception of solidity or projection, which arises from the *mental* combination of the two *dissimilar* pictures formed upon the two retinæ. It is easily shown, that any *near* object is seen in two different modes by the two eyes. Thus let the reader hold up a thin book, in such a manner that its back shall be exactly in front of his nose, and at a moderate distance from it; he will observe, by closing first one eye and then the other, that his perspective view of it (or the manner in which he would represent it on a plane surface) is very different, according to the eye with which he sees it. With the right eye he will see its right side, very much fore-shortened; with the left he will gain a corresponding view of the left side; and the apparent angles, and the lengths of the different lines, will be found to be very different in the two views. On looking at either of these views singly, no other notion of solidity can be acquired from it, than that to which the mind is conducted, by the association of such a view with the touch of the object which it represents. But it is capable of proof, that the mental association of the *different* pictures upon the two retinæ, does of itself give rise to the idea of solidity. This proof is afforded by Prof. Wheatstone's ingenious instrument, the Stereoscope, first described by him in 1838.*

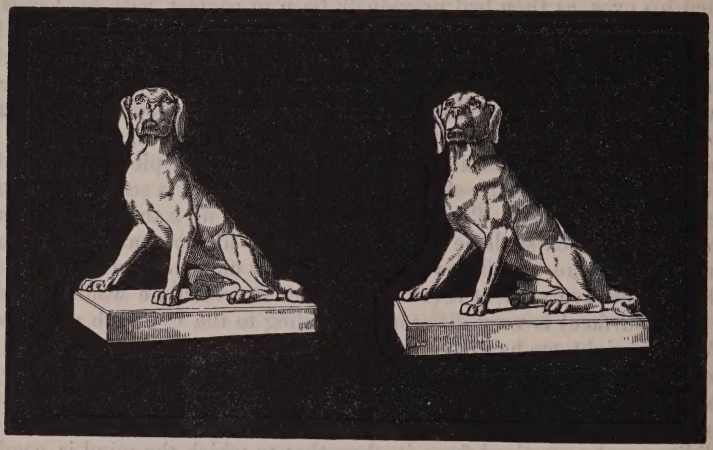
580. The *Stereoscope* in its original form essentially consists of two plane mirrors, inclined with their backs to one another, at an angle of 90°. If two perspective drawings of any solid object, as seen at a given distance with the two eyes respectively, such as those at A and B, Fig. 271, be so placed before these mirrors, one before each, that their two images shall be made to fall upon the corresponding parts of the two retinæ, in the same manner as the two images formed by the solid object itself would have done, the mind will perceive, not a single representation of the object, nor a confused blending of the two, but a projecting or receding surface, the exact counterpart of that from which the drawings were made.† The solid form if forcibly impressed on the mind, even when outlines only are given, especially if these be

* Various modifications of this instrument have been subsequently introduced; and there is one which has come into very extensive use, in which the two monocular pictures placed side by side, as in Figs. 271, 272, are viewed by the two eyes respectively through two halves of a convex lens. The great advantage of this instrument is its portability, and its enlargement of the pictures by the magnifying power of the lenses; but it is limited to pictures of small size, since the distance between corresponding points of the two pictures must not exceed the distance between the centres of the two eyes; and it is incapable of many adaptations which can be made with the mirror-stereoscope. In the Stereomonoscope of Claudet, the idea of relief is obtained by looking with both eyes at once on a ground-glass plate at the image produced by the coalescence of the two images of a stereoscopic slide, each refracted by a separate lens.—See "Proceed. of Royal Society," vol. ix. 1857–59, p. 194.

† The most striking effect is produced by two photographic pictures, taken at the same time by two cameras, so placed that their axes shall form the same angle with each other as that which the axes of the two eyes would form when looking at the same object. This adaptation, though the credit has been assumed by others, was originally devised by Prof. Wheatstone.

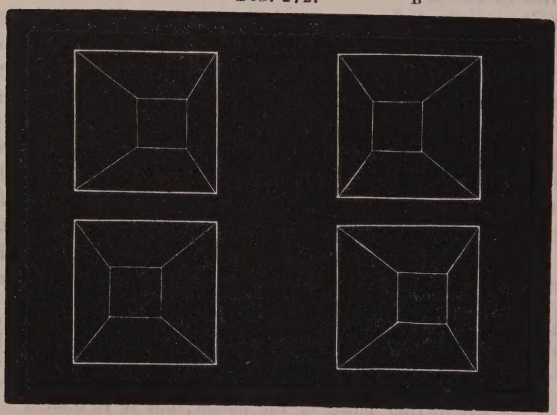
delineations of simple geometrical figures, easily suggested to the mind; and it may be readily shown that the very same outlines will suggest different conceptions, according to the mode in which they are placed. Thus in Fig. 272, the upper part of figures A, B, when combined in the Stereoscope, excite the idea of a *projecting* truncated pyramid, with the small square *in the centre*,

A FIG. 271. B



and the four sides sloping equally *away from* it; whilst the lower pair of figures, C, D, which are the same as the upper, but transferred to the opposite sides, no less vividly bring before the mind the visual conception of a *receding* pyramid, still with the small square in the centre, and the four sides sloping equally *towards* it. — Prof. Wheatstone has further shown, by means of the Stereoscope, that similar images, differing to a certain extent in magnitude, when presented to the corresponding parts of the two retinæ, give rise to the perception of a single object, intermediate in size between the two monocular pictures. Were it not for this, objects would appear single only when at an equal distance from both eyes, so that their pictures upon the retinæ are of the same size; which will not happen unless they are directly in front of the median line of the face. Again, if pictures of dissimilar objects be simultaneously presented to the two eyes, the consequence will be similar to that which is experienced when the rays come to the eye through two differently coloured media; the two images do not coalesce, nor do they appear permanently superposed one upon the other; but at one time one image predominates to the exclusion of the other, and then the other is

A FIG. 272. B



C D

seen alone ; and it is only at the moment of change that the two seem to be intermingled. It does not appear to be in the power of the Will, Prof. Wheatstone remarks, to determine the appearance of either ; but if one picture be more illuminated than the other, it will be seen during a larger portion of the time. If, however, the differences in the two pictures be such that the Mind can reconcile them, an *intermediate* conception is formed ; thus if two photographic portraits be taken at the proper angle for the Stereoscope, not simultaneously but consecutively, and the "sitter" alter his expression in the interval, so that one of the portraits represents him with a smile, and the other with a frown, the Stereoscopic image will present an intermediate expression of placidity*.—Many other curious experiments with this simple instrument are related by Prof. Wheatstone ; and they will go to confirm the general conclusion, that the combination of the dissimilar images furnished by the two eyes is *a mental act*, the resultant of which, in the case of all objects that are near enough to be seen in different perspective with the two eyes, is a mental image (referred to the visual sense) possessing the attributes of solidity and projection. In regard to distant objects, however, the difference in the images formed by the two eyes is so slight that it cannot aid in the determination ; and hence it is, that whilst we have no difficulty in distinguishing a picture, however well painted, from a solid object, when placed near our eyes (since the idea which might be suggested by the image formed on one eye will then be corrected by the other),† we are very liable to be misled by a delineation in which the perspective, light and shade, &c., are faithfully depicted, if we are placed at a distance from it, and are prevented from perceiving that it is *but* a picture.‡ In this case, however, a slight movement of the head is sufficient to undeceive us ; since by this movement a great change would be occasioned in the perspective view of the object, supposing it to possess an uneven surface ; whilst it scarcely affects the image formed by a picture. In the same manner, a person who only possesses one eye, may obtain, by a slight motion of his head, the same idea of the form of a body which another would acquire by the simultaneous use of his two eyes.§

581. Our appreciation of the relative Distances of *near* objects seems to be derived in like manner from the mental combination of the perceptions derived from the dissimilar pictures upon the two retinæ, assisted by the sensations derived from the muscles of the eyeballs, which are put in action to bring the optic axes into the requisite convergence. How much our right estimation of the relative distances of objects not too far from the eye depends upon the joint use of *both eyes*, is made evident by the fact that, if we close one eye, we find ourselves unable to execute with certainty many actions (such as threading a needle, or snuffing a candle) which require its guidance. In proportion as the object is approximated to the eyes, slight differences of distance produce marked differences in the degree of convergence, and these are readily appreciated so as to afford the means of very nice discrimination ;

* See Galton, 'Composite Portraits,' "Nature," vol. xviii. 1878, p. 97.

† It is a remarkable illustration of this principle, that a photographic representation of a landscape, building, &c., when viewed with *one eye* at a moderate distance, frequently brings the real scene far more forcibly before the mental vision than when it is looked at with both eyes ; since, in the latter case, the mind cannot avoid perceiving the flatness of its surface ; whilst in the former, the perspective, and the distribution of the lights and shadows, are free to suggest to the mind the relative distances and projections of the several parts.

‡ This delusion has been extremely complete, in some of those who have seen the panoramic view of London in the Colosseum. A lively and interesting account of it is given in the Journal of the Parsee Shipbuilders, who visited England some years ago.

§ For many interesting experiments with the stereoscope, see Mr. T. Towne in "Guy's Hospital Reports" for 1862 and 1863.

whilst, on the other hand, in proportion as they are removed farther and farther, do the optic axes approach parallelism, and the power of appreciating differences of distance is lost. It is the usual opinion that the muscular sensation which accompanies the inclination of the optic axes, *immediately suggests* the notion of the *distance* of an object; and that our appreciation of its *size* depends upon a secondary *interpretation* of the magnitude of its picture on the retina, on the basis of this notion. But it would appear from the experiments of Professor Wheatstone, that the reverse is the case; the sensation of convergence assisting in the first instance to determine the size, and the appreciation of distance being a secondary judgment based on this foundation (§ 584).—The power of estimating distance from the foregoing data, however, is obviously, in Man, not an intuitive but an acquired endowment; for it is evident to any observer, that infants, or older persons who have recently acquired sight, form very imperfect ideas respecting the distance of objects; their attempts to grasp bodies which attract their attention being for a long time unsuccessful, so that they only gradually learn to measure distances by the sight, through the medium of the touch. And it seems to follow from this, that even the notion of 'projection,' which we seem necessarily to form when looking at a solid object within a moderate distance, or at a properly-adjusted pair of Stereoscopic pictures, is not derived from an original intuition, but is the result of the association of our visual with our tactile experience, very early in life, so as to constitute a 'secondary intuition' on which all our subsequent appreciation of projection is based.

582. In regard to *remote* objects, our judgment of Distance is chiefly founded upon their apparent size, if their actual size be known to us; but, if this be not the case, and if we are so situated that we cannot judge of the intervening space, we principally form our estimate from that effect of different degrees of remoteness upon the distinctness of their colour and outline, which is known to Artists as 'aerial perspective.' Hence this estimate is liable to be greatly affected by varying states of the atmosphere, as is particularly known to every one who has visited warmer climates; where the extreme clearness of the air sometimes brings into apparently-near proximity a hill that rises some miles beyond a neighbouring ridge (the intervening space being hidden, so as not to afford any datum for the estimate of the distance of the remote hill), whilst a slight haziness carries its apparent distance to three or four times the reality. Additional means of judging of the distance of remote objects pointed out by Aubert,* are found in their parallax or apparent change of place, on the alteration of our own position with regard to them, and in the rate of movement, both absolute and relative, of the objects themselves, if they happen to be in motion.

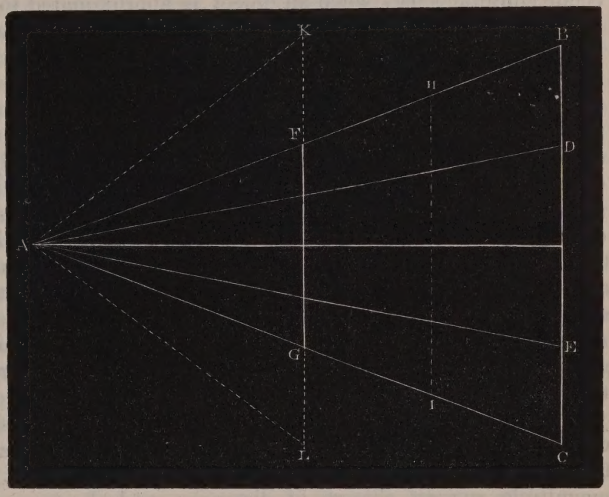
583. Our estimate of the Size of a *remote* object is partly dependent upon the *visual angle* under which we see it, and partly upon our estimate of its *distance*.† The 'visual angle,' formed by imaginary lines drawn from the eye (Fig. 273, A) to the extreme points, B, C, of the object, is the measure of the dimension of its image upon the retina; and it is obvious that, if two

* "Physiologie der Netzhaut," 1864, p. 17.

† When objects are so remote that we have no means of even approximately estimating their *distance*, we have no measure whatever of their *size*. Thus, the Sun and the Moon are of nearly the same apparent size to us, though one is about four hundred times the distance of the other; and we may cover either disc with a sixpence held near the eye, so as to be seen under the same visual angle; but we do not possess the least power of estimating the actual sizes of these objects, save by a calculation based on a knowledge of their relative distances.

objects, B C, D E, the former twice the length of the latter, be placed at the same distance, the visual angle B A C being twice as great as the angle D A E, the image of B C upon the retina will be twice as long as that of D E, and the mind will estimate their relative sizes accordingly. But if the distance of the object D E from the eye be diminished to one-half, so that it is brought into the position F G, its visual angle, and consequently the size of its image on the retina, will now be equal to that of B C; and the estimate we form of the relative sizes of the two will entirely depend upon the idea we entertain of their relative distances. Hence any circumstance which modifies that idea, produces a corresponding difference in our estimate of their size; so that the apparent size of an object, seen under a given visual angle, may be estimated as larger or smaller than the reality, according as we suppose it to be more or less distant than it really is. Of this we have a familiar instance in the fact, that if we meet a child whilst we are walking across a common in a fog (the flatness of the ground not giving us much power of estimating the intervening space), it appears to have the stature of a man, and a man seems like a giant; for the indistinctness of outline causes the mind to conceive of the figures as at a greater distance than they really are, and their apparent dimensions are augmented in like proportion. For if the object F G (Fig. 273) be *mentally carried-back* to the distance of D E, being still seen under the visual angle F A G (or B A C), it will appear to possess the length B C instead of D E. On the other hand, if the object B C were to be *mentally brought-forward* into the position K L, its apparent size being still determined by its visual angle, it will seem to be reduced to the length F G. That our estimate of the Size of *near* objects, however, depends upon a more direct process, seems to be a necessary inference from the following very ingenious experiments, made by Professor Wheatstone with a modification of his Mirror-Stereoscope, devised for separately testing the influence of the two conditions—namely, the magnitude of the retinal picture and the degree of convergence of the optic axes—which are ordinarily in action together. When an object is moved nearer to or farther from the eye, its *perceived* or estimated magnitude undergoes no change. But if two pictures, placed in the mirror-stereoscope, be made to move to and from the mirrors, in such a manner as to vary their *distances* from these (and therefore from the eyes), without altering the angle of convergence, their perceived magnitudes are augmented and reduced, in precise proportion to the increased and diminished sizes of the retinal pictures. Conversely, if the two pictures be made so to change their places in regard to

Fig. 273.



the mirrors (by moving in a horizontal circle, of which the middle-point between the mirrors is the centre), that the *angle of convergence* is increased or diminished, as it would be if the object were brought nearer to the eyes or removed farther from them, the perceived magnitude of the pictures is altered in an inverse manner; being reduced when the angle of convergence is increased, and increased when the inclination of the optic axes is lessened so as to approach parallelism. Thus it appears that the absence of alteration in the perceived magnitude of an object as ordinarily seen at varying distances, is the result of the inverse action of these two kinds of suggestion; for the enlargement of the retinal picture when acting alone, occasions an increase in the perceived magnitude, whilst an increase of convergence, taking place by itself, diminishes the perceived magnitude; and thus as these alterations occur simultaneously when an object is approximated to the eye, its dimensions seem to undergo no change; as will also be the case when, by the removal of the object to a greater distance, these conditions are again made to vary simultaneously, though in a contrary direction.—It may further be remarked, that, in the first of the foregoing experiments, the picture whose perceived magnitude is undergoing enlargement or diminution in consequence of the alteration of its retinal magnitude, seems evidently to be approaching or receding; yet if we fix our attention on it when it is stationary, at any instant, it appears to be at the same distance at one time as at another—the effect being very much like that of the Phantasmagoria, in which the alteration in the size of the images on the screen suggests the notion of their approach or recession, although we are quite sensible that the distance of the screen from our eyes remains constantly the same. In the second experiment, on the other hand, the picture whose perceived magnitude is undergoing diminution or enlargement in consequence of increase or lessening of the angle of convergence, does not appear either to approach or recede, and yet, when attentively regarded in different fixed positions, it is felt to be at different distances. Hence, as Professor Wheatstone observes, convergence of the optic axes suggests fixed distance to the mind, whilst variations of retinal magnitude suggest change of distance; and, however paradoxical it may seem, "we may perceive an object approach or recede, without appearing to change its distance, and an object to be at a different distance without appearing to approach or recede."*—A like alteration in apparent size is produced when two pairs of figures (such as those given in Fig. 272), the effect of one of which is to suggest a *projecting*, and that of the other a *receding* form, are viewed at the same time in the ordinary Stereoscope. For it will be observed that the relative size of the parts which appear to project is reduced, whilst that of the apparently-receding parts is augmented; as is particularly the case with the square truncated end of the pyramid, which is estimated by most persons as from one-third to one-half larger in each of its dimensions in the receding, than it is in the projecting pyramid, notwithstanding that the actual sizes of the squares in the two sets of figures are precisely the same. For supposing H I (Fig. 273) to represent the real side of one of the small squares, which becomes the truncated end of the pyramid; when this is brought-forward by the mind into the position K L, as the truncated top of a projecting pyramid, being seen under the visual angle H A I, its apparent size is reduced to F G; whilst, on the other hand, the very same square,

* See "Philos. Transact.," 1852, pp. 2–5. The Author thinks it well to add, that he has himself verified the above very curious results; which are scarcely less valuable contributions to the Physiology of Binocular vision, than those earlier attained by the same eminent experimentalist.

carried-back by the mind to the distance D E, as when it forms the truncated end of the receding pyramid, is mentally enlarged to the dimensions B C, the visual angle B A C being the same as H A I.

584. The large share which the Mind has in the interpretation of even such visual impressions as seem to us *necessarily* to induce particular perceptions, is further shown by a very remarkable class of phenomena, termed by Professor Wheatstone (their discoverer) *Conversions of Relief.* The simplest example of this class is presented by the alteration in the visual product of the same Stereoscopic pictures, when their positions are transposed. Thus the very same diagrams, which as placed in the upper part of Fig. 272, bring before the mind's eye the conception of a projecting pyramid, when changed to the position which they occupy in the lower part of that figure, call up the image of a receding pyramid. And a corresponding effect is produced by the reversal of any other pair of Stereoscopic pictures; all that should project being made to recede, all that should recede being made to project, *provided the converse has any meaning* which the Mind can readily appreciate.—But the same effects may be produced if the objects themselves are looked at by an instrument devised by Professor Wheatstone, and termed by him the *Pseudoscope;* the optical effect of which is, to reverse the ordinary visual relations between the near and distant parts of an object; the two conditions described in the preceding paragraph being combined inversely, so that as an object or part of an object is nearer the eye, its larger picture on the retina is accompanied by a diminished convergence of the optic axes. When the impression of a seal is looked at with this instrument, it is converted into the representation of the seal itself; or, if the seal be looked at, it presents the figure raised in relief, as in its ordinary impression. So, the inside of a cup or basin appears as a solid convex body; whilst the outside appears depressed and concave. A bust regarded in front becomes a deep hollow mask; whilst the interior of the cast of a face presents the appearance of the face in its ordinary relief. A china vase, ornamented with coloured flowers in relief, seems like a vertical section of the interior of such a vase, with hollow impressions of the flowers. The base of a brain seems concave, like the interior of the base of the skull which is its reflex; and the latter seems convex and projecting, like the base of the brain.—These and similar appearances are not always immediately perceived; and some present themselves much more readily than others. Those converse forms which we are *accustomed* actually to see, or which have a *meaning* that the mind can easily apprehend, are those which are most readily perceived. Thus, the illusion which may be produced with a bust or with the cast of a face, is not obtainable even by a lengthened pseudoscopic contemplation of the *real* face, which we cannot conceive of as thus 'turned inside out.' Another very interesting fact is, that those to whom the illusion does not at first present itself, usually find it *suddenly* come upon them after a little time, especially if they should have directed their minds to the imaginary conception of the object under its changed aspect. And, further, when the conversion has taken place, the natural aspect of the object continues to intrude itself, sometimes suddenly, sometimes gradually, and for a longer or shorter interval, when the converse will again succeed it. This is due to the involuntary alternation of the attention, between the conception suggested to the mind by the visual impressions derived from both eyes, and that which is derived from either eye singly; the latter, moreover, harmonizing with and being strengthened by our recollection of the object as we have seen it before, or (if it be new to us) by our notion of its natural appearance. A remarkable illusion in respect to the direction of lines is

exhibited in the accompanying diagram, constructed by Zöllner,* which, if regarded vertically, and still more if at an angle of 48° from the perpendicular with one eye, presents the following peculiarities:—Firstly, the dark longitudinal lines do not appear to be parallel, but to converge above and below alternately; secondly, the two halves of each oblique stria, traversing a longitudinal line, do not appear to be, as they really are, continuous with one another, but the lower half seems to be displaced downwards; and thirdly, sometimes, though not always, a stereoscopic effect is perceived, as though the lines were drawn on a sheet of paper folded longitudinally. Hering† explains this by a train of reasoning too long to be here inserted, but to the effect that all acute angles under 60°, on account of the natural curvature of the retina, appear less than they really are.

Fig. 274.

585. The *persistence* during a certain interval *of impressions made upon the retina*, gives rise to a number of curious visual phenomena, which can be here only briefly adverted to. The prolongation of the impression will be governed, in part, by its previous duration; thus, when we rapidly move an ignited point through a circle, the impression itself is momentary, and remains but for a short period; whilst, if we have been for some time looking at a window, and then close our eyes, the impression of the dark bars traversing the illuminated space is preserved for several seconds. One of the results of this persistence is the combination into a single image, of two or more objects presented to the eye in successive movements; but these must be of a kind which can be united, otherwise a confused picture is produced. Thus in a little toy, called the Thaumatrope, which was introduced some years ago, the two objects were painted on the opposite sides of a card—a bird, for instance, on one, and a cage on the other; and when the card was made (by twisting a pair of strings) to revolve about one of its diameters, in such a manner as to be alternately presenting the two sides to the eye at minute intervals, the two pictures were blended, the bird being seen in the cage. A far more curious illusion, however, was that first brought into notice by Professor Faraday; who showed that, if two toothed wheels, placed one behind the other, be made to revolve with equal velocity, a stationary spectrum will be seen; whilst if one be made to revolve more rapidly than the other, or the number of teeth be different, the spectrum also will revolve. The same takes place when a single wheel is made to revolve before a mirror, the wheel and its image answering the purpose of the two wheels in the former case. On this principle, a number of very ingenious toys have been constructed; in some of these, the same figure or object is seen in a variety of positions; and

* Poggendorff's "Annalen der Phys.," Band cx. p. 500.

† Funke's "Lehrbuch der Physiologie," vol. ii. 1866, p. 416.

the successive impressions, passing rapidly before the eye, give rise by their combination to the idea that the object is itself moving through these positions.*—It is interesting to remark, moreover, that when the eye has been for some time contemplating an object in motion, and is then directed towards stationary objects, *these* appear for a short time to have a like movement. Any railroad traveller may try this simple experiment, by first looking at the hedges, &c., which he is rapidly passing, and then at some part of the interior of the carriage itself, especially one which presents a series of parallel lines. But when the impression of movement has been of longer duration, its effects are less transient; thus a person who has been for some time on board ship, sees the floors, walls, and ceilings of his apartments on shore in a state of continual up-and-down motion, even for some days after he has landed. This would seem to be rather a *sensorial* than a *retinal* phenomenon.

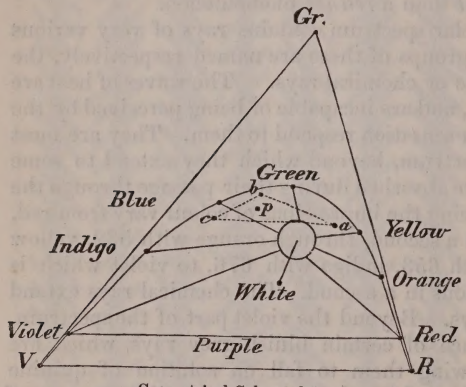
586. *Chromatoptometry.*—The solar spectrum contains rays of very various wave lengths or velocity, and three groups of these are named respectively, the calorific, the colorific, and the actinic or chemical rays. The waves of heat are longest, amounting to 0·00194 mm., and are incapable of being perceived by the retina, though the nerves of common sensation respond to them. They are most abundant at the red end of the spectrum, beyond which they extend to some distance, and 90 per cent. of them are absorbed during their passage through the media of the eye. The waves producing the impressions of colour vary from red, which has 481 billion vibrations in a second, through orange with 532, yellow with 563, green with 607, blue with 653, indigo with 676, to violet which is produced by 764 billions of vibrations in a second. The chemical rays extend some distance beyond the violet rays. Beyond the violet part of the spectrum, Helmholtz has observed the presence of certain bluish-grey rays, which are most easily demonstrated by allowing them to fall on solution of quinine sulphate, æsculin or petroleum, when they give rise to the phenomenon of fluorescence. The colorific rays are thus recognized by the number of their undulations in a second, and absorbed by the media of the eye about to the same extent as by water. The effects of the admixture of different colours may be investigated either by causing different colours from two solar or electric light spectra to fall on the same spot, or by looking obliquely through a glass plate at one colour whilst light of a different colour is reflected from the surface of the same plate, or by making a disk on which sectors of different colour are painted revolve rapidly, or lastly by looking, as in Scheiner's experiment, through two small holes separated from one another by a space less than the diameter of the pupil, and each of which is covered by a different coloured glass.† The three fundamental colours, as was originally shown by Thomas Young, are red, green and violet. The effects of a mixture of two simple but not complementary colours, is the same as that produced by the part of the spectrum which lies between them, after a certain amount of white light has been added to it. The less white that is combined with the mixture the more intense, or as it is sometimes termed, the more saturated is the tint of colour perceived. Hence the saturation of a colour

* A very beautiful "philosophical toy" was shown to the Author some years since, by its inventor, Mr. Roberts, the celebrated machinist of Manchester; consisting in an apparatus by which it was made possible to read words printed on a card, although the card itself was made to revolve on its axis even 40,000 times in a minute. The principle of its construction was simply this—that the eye caught a succession of glimpses of the card, through a narrow slit before which a disk with a single corresponding perforation was made to revolve; the rate of movement of this disk being so adjusted to that of the card, that whenever the eye caught sight of the latter, it was *momentarily* in the same position, so that, by the succession of transient impressions thus made upon the retina, the words printed on the card could be distinctly read.

† Landois, "Physiologie," 1880, p. 812.

diminishes with the intensity of the illumination under which it is seen. The accompanying diagram represents a geometrical colour plate, from which various conclusions can be drawn. In the centre is white, and from this point lines are drawn to the various points of the curve on which the names of the colours are described. Each would be most brightly illuminated towards the white end of the line, and most pure or saturated towards the opposite extremity. The effect of the mixture of two spectral colours may be obtained by drawing a straight line from the one point to the other; if then we suppose weights to hang from the two points of the curve indicating the position of the colours, and which weights shall represent the units of intensity of these colours, the position of the centre of gravities of the two in the line of junction will give the position in the plate of the mixed colour. Hence, the colour resulting from the mixture of two spectral colours, always lies on the straight line connecting the two colour points. Again, the complementary colour of a spectral colour may be immediately found if a line be drawn from the point of this colour through white, till it cuts the opposite part of the colour curve. The point where it cuts the colour curve shows the complementary colour. Lastly, the colour plate serves to discover the tint resulting from the admixture of three or more colours. Thus, for example, the effects of the admixture of the three colours, represented by the points *a* (pale yellow), *b* (nearly saturated greenish blue), and *c* (nearly saturated blue), may be determined by suspending weights from the three points which correspond to the intensity of each, and ascertaining the centre of gravity of the triangle *a b c*, which will lie at *p*. But this mixture of pale greenish blue, as may easily be seen can be also produced by the admixture of green blue with white, since *p* is also the centre of gravity of two weights which lie in the line joining white with green blue. The triangle *V Gr R* may also be drawn around the colour plate, and as the angles represent the three fundamental colours, red, green, and violet, it is obvious that every impression of colour that is in any point of the colour plate may be found if weights corresponding to the intensity of the fundamental colours be suspended from the angles of the triangle, for then the point of the colour table or the mixed colour, is the centre of gravity of the triangle thus weighted at its three angles. Each colour is perceived more distinctly in proportion to its *saturation*. By mingling it with white, its saturation may be diminished till at length it becomes invisible. Aubert* by experimenting with coloured pieces of paper placed on a rotating Maxwell's disk, finds that the limit of sensibility for a colour is reached when this is mixed with 120-180 parts of white. The influence of the *intensity* of a colour on its perceptibility is determined by mixing it with black, and Aubert† has shown that one part of colour on 359 parts of black is more than sufficient to produce a distinct impression of colour. As light fades into twilight and darkness, all colours become gre

Fig. 275.



Geometrical Colour plate.

in the following order: on a white ground, deep green, indigo, bright green, bright blue, red, yellow, and finally orange; on a black ground, deep green, brown, indigo, bright blue and bright green, red, yellow, and orange, which is thus always the last to be indistinguishable.* Colours which can no longer be distinguished when the eye is steadily fixed upon them, immediately re-appear when the position of the eye or of the coloured object is slightly altered. The retina is not equally susceptible to impressions of colour in all its parts.† It is only at the Fovea centralis, and the immediately adjoining part of the retina, that all shades of the primary colours can be clearly distinguished. The periphery of the retina is on the other hand insensitive to colour, all hues being only recognized as shades of which around the point of best vision in the centre of the retina‡ there is a zone where we perceive all of the so-called base colours, red, green, and violet. Outside of this is a zone in which green and violet are alone perceived, and beyond this another zone in which only blue or violet is perceived. Fick states§ that between the fovea and the periphery is an intermediate zone in which the sense of colour is imperfect, red, yellow, and green giving the impression of yellow, which is paler the greener the tint when seen in the polar zone, whilst blue and violet give the impression of blue, which is also paler, the nearer to green is the sensation produced when seen at the polar zone. The three zones named respectively the polar, the intermediate, and the peripheric zone, are by no means sharply defined from each other, and the influence of magnitude is considerable, the perception of the colour of a small object being much less accurate in the intermediate zone than that of a larger object.

587. When the Retina has been exposed for some time to a strong impression of some particular kind, it seems less susceptible of feebler impressions of the same kind. Thus, if we look at any brightly luminous object, and then turn our eyes on a sheet of white paper, we shall perceive a dark spot upon it; the portion of the retina which had been affected by the bright image, not being able to receive an impression from the fainter rays reflected by the paper. The dark spectrum does not at once disappear, but assumes different colours in succession—these being expressions of the states through which the retina is passing in its transition to the natural condition. If the eye has received a strong impression from a *coloured* object, the spectrum exhibits the *complementary* colour;‖ thus, if the eye be fixed for any length of time upon a bright red spot on a white ground, and be then suddenly turned so as to rest upon the white surface, we see a spectrum of a green colour. This, according to Helmholtz, is due to the fact that certain nervous elements destined to conduct impressions of red are fatigued; other elements, on the contrary, and especially those adapted to conduct impressions of green are at rest, but white light contains all colours, and green amongst the others, which, as the green-perceiving elements are not exhausted, are brought vividly into

* The experiments of Purkinje, Dove, and Grailich, are not in accord with those of Aubert, for they are of opinion that red is distinguished in twilight with greater difficultythan blue.

† Purkinje long ago stated that the periphery of the retina exhibits defective perception of different colours, red light appearing grey; yellow, green; green, bluish; whilst blue and violet are unaltered; and the recent investigations of Fick, "Arbeiten aus dem Physiol. Laborat. der Würzburger Hochschüle," 1878, Heft iv. p. 213. See also Holmgren, "Die Farbenblindheit," 1878; and Cohn, "Studien über Farbenblindheit," 1879.

‡ See Joy Jeffries' "Color Blindness."

§ "Physiol. Optik," Hermann's "Handbuch der Physiol.," Band iii. p. 206.

‖ By the 'complementary' colour is meant that which would be required to make white or colourless light, when mixed with the original: thus red is the complement of greenish blue (which may be made by mixing yellow and blue); blue is the complement of orange (red and yellow); and greenish yellow of purple (red and blue); and *vice versâ* in all instances.

view. In like manner each spectral colour can be rendered uncommonly vivid by previously exhausting the retina by gazing intently on its complementary colour.—The same explanation applies to the curious phenomenon of 'coloured shadows.' It may not unfrequently be observed at sunset, that, when the light of the sun acquires a bright orange colour from the clouds through which it passes, the shadows cast by it have a blue tint. Again, in a room with red curtains, the light which passes through these produces green shadows. In both instances, a strong impression of one colour is made on the general surface of the retina: and at any particular spots, therefore, at which the light is colourless but very faint, that colour is not perceived, its complement only being visible. The correctness of this explanation is proved by the fact, that, if the shadow be viewed through a tube, in such a manner that the coloured ground is excluded, it seems like an ordinary shadow. It is not unlikely that, as Müller suggests, the predominant action of one colour on the retina disturbs (as it were) the equilibrium of its condition, and excites in it a tendency to the development of a state corresponding to that which is produced by the impression of the complementary colour; for the latter is perceived, as he remarks, even where it does not exist; as when the eye, after receiving a strong impression from a coloured spot, and being directed upon a completely dark surface or into a dark cavity, still perceives the spectrum. This change, indeed, extends beyond the spot on which the impression is made (§ 592); for, as is well known to artists, the sensory impression producing any colour is greatly affected by neighbouring hues. Thus, if four strips of coloured paper, or any other fabric, A, B, C, D, —two of them, A, B, of one colour (*e.g.* red), and the other two, C, D, of some different colour (*e.g.* blue)—be laid side-by-side at intervals of about half an inch, the hues of the two central strips, B, C, will be decidedly modified by each other's proximity, each approximating to the hue of the complementary colour of the other; so that instead of

A	B	C	D
red	red	blue	blue,

we shall see

A	B	C	D
red	orange-red	greenish-blue	blue.

In the experiments of Mandelstamm,* it was found that the acuteness of perception of the eye for slightly different shades of colour was greatest in the yellow spectrum, and then successively less in the blue, green, indigo, and finally, in the red, in which it was least.† Lamansky‡ finds that the sensitiveness of the eye for colour is greatest in the order green, yellow, and blue, and least for red. In commencing atrophy of the optic nerve, red colour blindness first appears. Lamansky finds the time requisite for the perception of red three times greater than that for blue. Kunkel, however,§ states that the order of rapidity of perception is, red (0·0573 sec.), blue (0·0916 sec.), and green (0·133 sec.) The time requisite for distinct vision of a line is extremely brief. From experiments with the Electric Spark, O. N. Rood‖ estimates it for a black line at not more than four billionths of a second (0·000,000,868 sec., Landois). The means by which differences of colour are recognized are at present unknown. Young suggested that there might be

* "Archiv f. Ophthalmol.," Band xiii. Abtheil. ii. p. 399.

† A remarkable phenomenon of recurrent vision is described by Prof. Young in "Amer. Journ. of Sci.," vol. iii. No. 16.

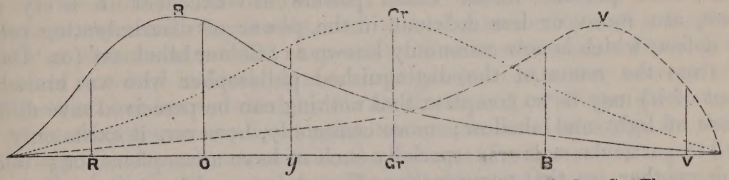
different nerves, each having the power of discriminating one of the fundamental colours, but the structure of the retina gives no support to this view. The laminated structure observed by Max Schultze in the proximal extremities of the rods and cones may possibly have some relation to this power, for if the laminæ possessed a different refractive power in the several rods and cones, they would only transmit light of a certain colour.

588. To explain the mode in which light of various colours is perceived, it has been suggested that the Retina may contain three kinds of nerve termination, one of which when stimulated produces the sensation of red, a second of green, and a third of violet; the red perceiving elements are most strongly stimulated by the waves of greatest length in the spectrum; the green perceiving elements by those of medium length, and the violet perceiving elements by those of shortest length. At the same time it must be admitted

Fig. 276.



Distribution of colour in the Spectrum. R. The distribution of Red. Gr. The distribution of Green. V. The distribution of Violet.

that each colour of the spectrum stimulates all the elements, though some more feebly, and others more powerfully. Fig. 276 shows, by means of three curves, the mode in which the various sensations of colour may be produced. The continuous line represents red; the dotted line, green; the interrupted line, violet. Pure red as shown by the height of the ordinates stimulates the red perceiving elements of the retina strongly, the others more feebly, and the sensation perceived is red. Pure yellow stimulates the red and green perceiving elements moderately, the violet perceiving elements feebly, and the sensation produced is that of yellow. Pure green strongly stimulates the green perceiving elements, and much more feebly the two other kinds, giving the sensation of green, and so with the blue and violet. The sensation of a mixed colour results from the simultaneous stimulation of two kinds of elements, and if all are stimulated, the sensation of white light is experienced. As the recognition of colour is most acute at the fovea centralis, and as at this part there are no rods, but cones alone, it has been concluded that the perception of colour is a function of the cones and not of the rods. The latter would appear to possess only the power of appreciating quantitative variations in the amount of light.

589. The observations of Schultze seem to point clearly to the conclusion that the perception of colours is due to the cones and not to the rods, for not only is the fovea centralis of the human eye, where cones alone are present, the part most acutely sensitive to variations of colour, but in animals of nocturnal habits like the owl and the bat, no cones are discoverable, and we may conclude that vision in them is reduced to the quantitative perception of light; or, in other words, to the differences between shades of light and darkness. A simple experiment shows that our notions of colour are, like those of temperature, relative and not positive, for although, when a pair of smoked glasses are worn before the eyes, surrounding objects at first appear strongly tinged with their colour, very short experience enables the wearer to distinguish between different colours, and he sees, or seems to himself to

see, white objects of a fine white colour, until he undeceives himself by removing them.

590. Upon the properties of the Eye in regard to Colour are founded the laws of harmonious colouring, which have an obvious analogy with those of musical harmony. All complementary colours have an agreeable effect when judiciously disposed in combination; and all bright colours, which are not complementary, have a disagreeable effect, if they are predominant: this is especially the case in regard to the simple colours, strong combinations of any two of which, without any colour that is complementary to either of them, are extremely offensive. Painters who are ignorant of these laws, introduce a large quantity of dull grey into their pictures, in order to diminish the glaring effects which they would otherwise produce; but this benefit is obtained by a sacrifice of the vividness and force, which may be secured in combination with the richest harmony, by a proper attention to physiological principles.*

591. Some persons whose visual powers are excellent in every other respect, are more or less deficient in the power of discriminating *colours*. This defect, which is now commonly known as 'Colour blindness' (or 'Daltonism,' from the name of the distinguished philosopher who was himself the subject of it) may be so complete, that nothing can be perceived save different degrees of light and shadow; more commonly, however, it exists only with regard to particular colours, especially such as have a complementary relation to one another, so that persons thus affected are unable (*e.g.*) to distinguish ripe cherries among the leaves of the tree, save by their form; whilst in some individuals it does no more than confuse colours that are nearly related, such as green and blue, especially when they are seen by artificial light.† If we accept three fundamental colours, red, green, and violet, the failure to distinguish between these is termed partial colour-blindness, whilst inability to distinguish any colour at all is termed total colour-blindness. Holmgren has proposed that if the several shades of a given colour cannot be perceived, the condition should be termed complete, whilst if they can be distinguished, it should be called incomplete colour-blindness. In testing these conditions, a very requisite proceeding in signalmen, wools of various colour are placed before the patient. There are three kinds of colour-blindness, red blindness, green blindness, and violet blindness.‡ He who to a purple sample adds blue and violet strands, or either of these two, is red blind; but he who adds to the purple, green or grey or both, is green blind. The man who is violet blind adds to the purple, red and orange. A green sample may also be placed before the patient, because it is very easily confounded with grey. The very numerous examinations of school children in America by Joy Jeffries§ have shown that in that country 4·202 per cent. of boys

* This subject has been most carefully and elaborately investigated by M. Chevreul, whose recent Treatise on Colours has almost exhausted the inquiry into the mode in which the Visual sense of Man is affected by them. For a general view of the nature and attributes of Light, see Art. 'Light,' by Sir J. Herschel, in the last edition of the "Encyclopædia Metropolitana."

† See especially the Memoir of Prof. Seebeck, in Poggendorff's "Annalen," Band xlii. (1837); that of Prof. Wartmann, in "Taylor's Scientific Memoirs," vol. iv. p. 156; Mr. Pole's case recorded in the "Proceedings of the Royal Society," 1856–57, vol. viii. p. 172, and the interesting commentary upon it by Sir J. Herschel, in idem, vol. x. p. 72. See also Preyer, "Centralblatt," 1869, p. 72. A difference appears to exist between the effects of reflected and transmitted light in cases of colour-blindness. See Jeaffreson, "Lancet," 1872 ('Anerythropsia or true Daltonism'), pp. 601, 670. Clarke, idem, p. 635.

‡ See Michel, "Die Prüfung des Sehvermögens." München, 1878.

§ See 'Report in School Document,' No. 13, of the examination of 27,927 school children for colour-blindness, March, 1880.

are colour-blind, and only 0·066 per cent. of girls. Cohm* observed the same remarkable rarity of colour-blindness in women, and his average in males was 4 per cent. The proportion of cases of colour-blindness in Jews as compared with Christians in Breslau is as 4·8 : 3·6. Red blindness is by far the most common, constituting 80 per cent. of all cases. The ordinary form of colour-blindness seems to be only an extension of the want of perceptivity normal in the periphery of the Retina.†

592. The impressions made by luminous objects upon the Retina are not precisely confined to the spots upon which their rays impinge, but extend themselves to a greater or less distance around; which phenomenon has been termed *irradiation*. Thus if we make a circular white spot upon a black ground, and a black spot of precisely the same dimensions upon a white ground, the former will seem to be considerably larger than the latter; apparently because the excitation of the retina by the luminous impression tends to spread itself in each case over the adjacent non-excited space. Hence it is that we are able to distinguish any small magnitudes, such as letters or the lines of a diagram, at a much greater distance when they are marked in white on a black ground, than when inscribed in black upon a white ground. Another curious case of the same kind has been noticed by Sir D. Brewster.‡ "If we shut one eye, and direct the other to any fixed point, such as the head of a pin, we shall see indistinctly all other objects within the sphere of vision. Let one of these objects thus indistinctly seen, be a strip of white paper or a pen lying on a green cloth. Then, after a short time, the strip of paper, or the pen, will disappear altogether, as if it were entirely removed; the impression of the green cloth upon the surrounding parts of the retina, extending over that part of it which the image of the pen occupied. In a short time the vanished image will re-appear, and again vanish; when both eyes are open, the very same effect takes place, but not so readily as with one eye. If the object seen indistinctly is a black stripe on a white ground, it will vanish in a similar manner. When the object seen obliquely is luminous, such as a candle, it will never vanish entirely, until its light is much weakened by being placed at a great distance; but it swells and contracts, and is encircled by a nebulous halo."

593. The power of receiving and transmitting visual impressions is by no means uniformly diffused over the entire Retina. In the whole field of vision which at any time lies before us, we only see with perfect distinctness that part to which the axes of our eyes are directed, and of which the image, therefore, is formed upon the 'yellow spot.' Nevertheless we have a sufficiently distinct perception of the remainder of the field, to enable us to judge of the relations of the objects which are distinctly seen to those which surround them; and the mobility of our eyes enables us, under the guidance of our visual sense, to direct the most sensitive spot of the retina to

* "Studien üb. angeb. Farbenblindheit," 1879.

† For an interesting case in which the patient was affected with monocular green blindness and could yet see blue, though this colour, if it were a mixture of green and violet, ought to have appeared violet to him, see Preyer, "Centralblatt," 1872, No. 8; see also Lebert, "Klin. Monatschr. f. Augenheilk.," 1873, p. 867. The observations of Schelske (Gräfe's "Archiv," Band ix. Heft iii. p. 41) and Woinow (idem, Band xvi. Heft i. p. 200) have shown that the peripheral parts of the retina are, even in healthy persons, insensible to red, and perhaps to green, the latter colour being perceived as yellow. See also Rahlmann, Abst. in "Centralblatt," 1873, p. 357. Niemetschek, "Prag. Vierteljahrs.," Band c., 1868, p. 224, thought that in the colour-blind the distance between the eyes was abnormally small, and that this was due to imperfect development of the frontal convolutions, but this has been refuted by Holmgren, v. Gräfe's "Archiv," Band xxv. p. 135.

‡ 'Treatise on Optics,' in Lardner's "Cyclopædia," p. 296.

every part of the field in succession, not only without effort, but even almost without the consciousness that we are doing so.—Generally speaking, the indistinctness of vision for objects seen out of the axis of the eye, increases with the distance of their images from the central point; or, in other words, the impressibility of the several parts of the retina diminishes according to their distance from the 'yellow spot.' For a small space around it, however, the vision is tolerably accurate, and the extent of this circle or clear 'indirect vision,' as it is termed, varies in different people; Volkmann, for instance, can read an entire word by the light of a single electrical spark, and must therefore have instantaneously a direct and perfect perception of every part of it, whilst by others only a letter or two can be distinguished. It appears also from the experiments of Aubert and Förster,* and of Heymann,† that when the eye is accommodated for near objects, the limits of clear lateral perception are increased, or at least the perceptibility of that circle is intensified; so that of two objects which throw images of equal size on the retina, the smaller and more approximated one is distinctly perceived at a greater distance from the yellow spot than the larger and more distant object. But there is one part of the retinal surface—namely, the seat of entrance of the Optic Nerve, which is remarkable for its imperfect receptivity; as is shown by the following experiment. Let two black spots be made upon a piece of paper, about four or five inches apart; then let the left eye be closed, and the right eye be strongly fixed upon the left-hand spot; if the paper be then moved backwards and forwards, so as to change its distance from the eye, a point will be found at which the right-hand spot is no longer visible, though it is clearly seen when the paper is brought nearer or removed farther. In this position of the eye and the object, the rays from the right-hand spot cross to the nasal side of the globe, and fall upon the point of the retina which has just been mentioned. If the same experiment be tried with candles, the image will not entirely disappear, but will become a cloudy mass of light. It is not correct to say, as is sometimes done, that the retina is not impressible by light at this point; since, if such were the case, we should see a dark spot in our field of view whenever we use only one eye, which is not the case. The fact seems rather to be, that this portion of the retina is very inferior to the surrounding parts in its receptivity for luminous impressions; whilst, on the other hand, there is an unusual tendency to the extension of *their* condition to it by 'irradiation' (§ 592); so that, in the experiment just described, if the black spots be made upon a coloured ground, this colour will take the place of the spot which disappears.‡

594. That an electrical current is produced when light is allowed to fall upon the Retina, was first established by Holmgren.§ He observed an oscillation of the needle of the galvanometer under these circumstances in all vertebrates except Fishes. In the Frog the oscillation is positive, but in all others it is negative, but positive when the light is withdrawn; the yellow rays are the most active in this respect. The subject has been also taken up by Dewar and McKendrick,‖ who have corroborated and extended Holmgren's observations. The impression made by rays of light upon the Retina may be to a certain extent imitated by other physical agencies, which thus give rise

to various *subjective* visual phenomena. Advantage has recently been taken by Dr. Serre,* of the power of mechanical pressure to produce luminous spectra, for the investigation of the 'law of visual direction'; and the results which he has obtained are of very great interest. When any part of the globe of the eye is compressed (the experimenter being in a completely darkened room), a luminous figure is seen to be projected in the direction opposite to the spot pressed upon. Its form varies according to that of the compressing body, and to the degree in which the retina is affected by it. Thus if the pressure be made by the point of the finger, or by any other circular surface, upon a part of the globe over the interior of which the retina is continuous, the spectrum, or *phosphène* (as it is termed by Dr. Serre), is also circular ; if the compressing body, on the other hand, be square at its extremity, the 'phosphène' is also square ; and if it be triangular, the 'phosphène' is triangular too. But if the pressure be made near the anterior edge of the retina (which is what most commonly happens, unless the most favourable situation be designedly chosen), the figure of the 'phosphène' is incomplete ; and the degree of its deficiency corresponds with the proportion of the area of compression that does not lie over the retinal expansion. Hence there can be no hesitation in regarding the production of this spectrum as the immediate result of the affection of the sensorium by the pressure of the retina ; and as it seems to our perceptive consciousness to have a distinct objective existence, and as its position bears a constant and definite relation to that of the portion of the retina on which the impression is made, it seems obvious that any such affection of the retina not only immediately suggests to our minds the notion of an external objective cause of the impression, but also indicates to our consciousness the *direction* of the object.—But further, besides the principal 'phosphène,' another, of smaller dimensions, is usually to be seen, in a direction nearly the same as that on which the pressure is made ; this is the result of the transmission of the pressure to the *opposite* side of the globe, by an alteration of its figure and of the position of its contents, which corresponds to the fracture of the skull by *contre-coup*. The form of this smaller or secondary 'phosphène' is not affected by the cause which sometimes renders the larger or primary spectrum incomplete ; since, as we cannot anywhere apply pressure to the living Human eye, save on some part of its anterior hemisphere, the 'contre-coup' will always take place at the opposite spot in the posterior hemisphere, over which the retina is continuous, save at the entrance of the optic nerve. By an extensive series of observations upon the relation of the positions of the primary and secondary 'phosphènes,' both to each other and to the seat of compression, Dr. Serre has deduced the important conclusion, that the lines joining the imaginary spectra and the spots of the retina from whose affection they respectively proceed, pass through a common 'centre of direction,' whose position is in the middle of the crystalline lens. And hence it seems to be a legitimate conclusion, that our sense of the relative directions of external objects is derived from a kind of mental projection of each point of the retinal image, in the line which joins it to this 'centre of direction.'

595. Another very curious *subjective* phenomenon of Vision, is the representation which, under particular circumstances, we may mentally obtain of the retina itself; as in the following experiment, first devised by Purkinje, and known by his name. "If in a room otherwise dark, a lighted candle be moved to and fro, or in a circle, at a distance of six inches before the eyes, we perceive, after a short time, a dark arborescent figure ramifying over the

* See his "Essai sur les Phosphènes," Paris, 1853.

whole field of vision, this appearance is produced by the vasa centralia distributed over the retina, or by the parts of the retina covered by those vessels. There are, properly speaking, two arborescent figures, the trunks of which are not coincident, but on the contrary arise in the right and left divisions of the field, and immediately take opposite directions. One trunk belongs to each eye, but their branches intersect each other in the common field of vision. The explanation of this phenomenon is as follows:—By the movement of the candle to and fro, the light is made to act on the whole extent of the retina, and all the parts of the membrane which are not immediately covered by the vasa centralia are feebly illuminated; those parts, on the contrary, which are covered with these vessels, cannot be acted on by the light, and are perceived, therefore, as dark arborescent figures. These figures appear to lie before the eye, and to be suspended in the field of vision;"* and as the vessels appear magnified, and display a remarkable parallactic gliding movement over the visual field, data are afforded by which H. Müller has calculated that the true percipient surface of the retina must be situated at a certain distance from the vessels, corresponding in fact with the bacillar layer.† We have thus another demonstration of the fact, that, in ordinary Vision, the immediate object of our sensation is a definite condition of the retina, which is excited by the formation of a luminous image. The power of summoning up at will the visual representation of external objects, and especially of figures in the acts of mental calculation, the recollection of dates, and other mental processes, appears from the inquiries of Francis Galton,‡ who has applied the term 'visualization' to it, to be of not unfrequent occurrence. In such cases the figures arrange themselves in a series more or less irregular or interrupted in position—sometimes in vertical, at others in horizontal rows, certain numbers or groups of numbers being sometimes shaded or even coloured. This faculty seems to be more common in children than in adults.

596. The visual power is susceptible of extraordinary improvement, through the habitual direction of our *attention* to the effects produced upon our consciousness by the impressions transmitted to the Sensorium from the Eye; and this improvement may take place, either in regard to the quickness and readiness with which objects generally are perceived, or in the faculty of discriminating the slightest differences in form, shade, colour, &c., or of discerning bodies of extreme minuteness. In regard to all these points it may be noticed that the habit of attention to any particular class of objects, sharpens the discriminating power for that class alone; and that it is usually rather the mental than the corporeal vision which undergoes improvement. Thus the Seaman who makes out the 'loom of the land' where the landsman can discern nothing but an indefinite haze above the horizon, or who can distinguish the size, rig, and course of a vessel which the landsman can but just see as a formless speck, does so in virtue of the aptitude of his mind for receiving suggestions from minute indications such as pass unnoticed by those who have not been accustomed to form their ideas upon the same kind of experiences. And the Microscopist, who is constantly on the outlook for the various forms of organic structure with which his mind is familiar, discerns these without difficulty or hesitation, where an ordinary observer sees nothing

* Müller's "Elements of Physiology" (Baly's Translation), p. 1163.

† For the explanation of various other entoptical phenomena, see James Jago, B.A., in "Proceedings of the Royal Society," vol. viii. p. 603. He observes that the long beams of light which issue from flames regarded with 'winking eyes' proceed from little bars of fluid along the margins of the lids.

‡ See "Nature," vol. xxi. 1880, p. 252, *et seq.*

but a confused jumble of tissue. Extremely slight variations in the relative illumination of two objects can readily be discerned. According to Arago* the difference can be perceived when it amounts to no more than about 1-64th, according to Volkmann when it is from 1-60th to 1-100th, to Steinheil 1-38th, and to Masson 1-120th. Aubert† has shown that these variations in the results obtained by different observers are probably due to their having employed different amounts of illumination; since the perception of slight variations is much greater, within certain limits, with moderately bright than with feeble illuminating powers.—It is interesting to observe that the power of descrying objects at vast distances appears to be hereditarily possessed by two races of men, the Mongols of Northern Asia, and the Hottentots of Southern Africa, both of which habitually dwell on vast plains that seem to stretch without limit in every direction. It seems probable that this power was in the first instance acquired by habit in each case; and that, as frequently happens with acquired peculiarities which are kept up by constant use in successive generations,‡ it has become fixedly hereditary.

6. *Sense of Hearing.*

597. In the Ear, as in the Eye, the impressions made upon the sensory nerve are not at once produced by the body which originates the sensation; but they are propagated to it, through a medium capable of transmitting them. We obviously take cognizance by the mind, therefore, not of the sonorous object, but of the condition of the auditory nerve; and all the ideas we form of sounds, as to their nature, intensity, direction, &c., must be based upon the changes which they produce in it. The complex contrivances which we meet with in the organ of Hearing among higher animals, are evidently intended to give them greater power of discriminating sounds than is possessed by the lower tribes; in which last it is reduced to a form so simple that it may be questioned whether they can be said to possess an organ of *hearing*, if by this term we imply anything more than the mere consciousness of sonorous vibrations.—There is a considerable difference, however, between the Eye and the Ear, in regard to the special purposes for which they are respectively adapted. In the former we have seen that the whole object of the instrument is to direct the rays of light received by it, in such a manner as to occasion them to fall upon the expansion of the optic nerve in similar relative positions, and with corresponding proportional intensities, to those which they possessed when issuing from the object. We have no reason to believe anything of this kind to be the purpose of the Ear; indeed it would be inconsistent with the laws of the propagation of sound. Sonorous vibrations having the most various directions, and the most unequal rates of succession, are transmitted by all media without modification, however numerous their lines of intersection; and wherever these undulations fall upon the auditory nerve, they must cause the sensation of corresponding sounds. Still it is probable that some portions of the complex organ of hearing, in Man and in the higher animals, are more adapted than others to receive impressions of a particular character; and that thus we may be especially informed of the direction of a sound by one part of the organ, of its musical tone by another, and some other of its qualities by a third.

598. A single impulse communicated to the Auditory nerve through an appropriate apparatus, seems to be sufficient to excite the momentary sensation of *sound;* but most frequently a series of such impulses is concerned, there

* "Astronomie," vol. i. p. 194. † "Physiologie der Netzhaut," 1864.

‡ See "Princ. of Comp. Physiol.," § 620.

being but few sounds which do not partake, in a greater or less degree, of the character of a *tone*. Any continuous sound or tone is dependent upon a succession of impulses; and its acuteness or depth is governed by the rapidity with which these succeed one another. It is not difficult to ascertain by experiment, what number of such impulses or undulations are required to give every tone which the ear can appreciate. Thus if, as in the instrument termed the Syren, a circular plate with a number of apertures at regular intervals be made to revolve over the top of a pipe through which air is propelled, a succession of short *puffs* will be allowed to issue from this; and, if the revolution be sufficiently rapid, these impulses will unite into a definite tone. In the same manner, if a spring be fixed near the edge of a revolving toothed wheel, in such a manner as to be caught by every tooth as it passes, a succession of *clicks* will be heard; and these too, if the revolution of the wheel be sufficiently rapid, will produce a tone. The number of apertures in the plate which pass the orifice of the pipe in a given time, or the number of teeth which pass the spring, being known, it is easy to see that this must be the number of impulses required to produce the given tone. Each impulse produces a double vibration, forwards and backwards (as is seen when a string is put in vibration, by pulling it out of the straight line); hence the number of single vibrations is always double that of the impulses.—The maximum and minimum of the intervals of successive pulses, still appreciable by the ear as determinate musical sounds,* in persons endowed with an acute sense of hearing, may vary from 8 for the lowest, to above 40,000 for the highest note. Blake found that children of 12–13 years of age could perceive a note produced by 40,960 single vibrations at a distance of 34 feet. Young persons of 18–20 years heard the same only at a distance of 13–16 feet, but a note produced by 36,864 simple vibrations at 34 feet. Adults of 28–30 years could only hear at 34 feet a note produced by 32,768 vibrations. The deepest tone of orchestral instruments is the E of the Double Bass with $41\frac{1}{4}$ vibrations, the highest the d^v of the Piccolo flute with 4,752 vibrations (Tyndall). From the observations of Dr. Wollaston, it is evident that the ears of different individuals are differently constituted in this respect; some not being able to hear very acute tones produced by Insects, or even Birds, which are distinctly audible to others, whilst the same difference in the perception of low notes has been observed not only in different persons, but in the opposite ears of the same individual.† In regard to the precise time during which a sonorous impression remains upon the ear, it is difficult to procure exact information, since it departs more gradually than do visual impressions from the eye. This is certain, however—that it is much longer than the interval between the successive pulses in the production of tones; since it was found by M. Savart, that one or even several teeth might be removed from the toothed wheel, without a perceptible break in its sound—showing that, when the tone was once established, the impression of it remained during an intermission of some length. In Helmholtz's experiments it was observed that when the duration of each note in a succession of similar notes was less than 0·1 sec., the sound became continuous.

599. A very recondite investigation into the theory of Acoustics, and especially into the conditions on which the distinct qualities of musical tones

* Despretz, "Comptes Rendus," tom. xx. p. 1214. Hermann, "Grundriss der Physiologie," 1867, gives the limits at 40 and 16,000 double vibrations; Helmholtz at 16 and 38,000 single vibrations, or about 11 octaves. ("Boston Med. and Surg. Journ.," 1872, (vol. x. No. 20); Pfaundler ("Sitz. d. Wiener Akad.," Band lxxvi. 1877, p. 561) considers that only two beats in a second are required to produce an audible note.

† Högyes, "Medicin. Natur-wiss. Anzieger," 1879, p. 90.

depend, was undertaken by Helmholtz.* It is possible, he observes, to produce sounds consisting of only a single primary or *fundamental note;* the fundamental note of a sonorous body being the lowest tone which it yields when the whole of it is in vibration together; but in by far the greater number of instances, sounds, however produced, and whether musical in their character or not, are compounded of the fundamental note and a number of secondary, collateral, or harmonic notes; and the peculiar quality or *timbre* of particular instruments appears to be determined by a variation in the mode of grouping of the secondary sounds. Each such group Helmholtz designates a "sound colour." In a series of experiments upon the vowel sounds, *a*, *e*, *i*, *o*, and *u*, he has remarked that we distinguish them from one another† by the harmonic sounds which accompany the chief or fundamental note, and he endeavours to render this evident by the following experiments. He terms the fundamental note the first (1), whilst the harmonics (2, 3, 4, 5, 6, &c.) are notes produced by two, three, four, five, or six times the number of vibrations of the fundamental note. Thus, taking the middle C of the piano as the fundamental note, the harmonics will be C_2 (octave) G, C_3 (double octave) E_3 G_3, &c.

2 3 4 5 6

Now if the vowel *a* be sung close to a piano with the damper up, not only will the wire corresponding to the fundamental note be thrown into vibration, but also the wires corresponding to the 3rd and 5th harmonics, or those vibrating three times and five times as often as the fundamental note, and also more feebly the 2nd, 4th, and 7th harmonic notes. When the vowel *o* is sung, the 3rd harmonic note vibrates somewhat more weakly than when *a* is sung; the 2nd and 5th harmonics very weakly. With *u* the fundamental note vibrates almost alone; the 3rd harmonic very feebly. With *e* the wire of the 2nd harmonic is thrown into powerful vibration, but the higher harmonics are scarcely produced. With *i*, as with *u*, it is difficult to pronounce it loudly enough to excite vibrations in any but the fundamental note; the 2nd and 3rd harmonics, however, appear to aid in determining the clear character of the note, and slight vibrations may be observed in the 5th harmonic. The wires of the piano in these instances may be said to analyze the vocal sound into its secondary elements or partial notes; and Helmholtz has shown that the same result may be attained by placing in connection with the ear a series of glass vessels, producing by their vibration harmonic notes, and ascertaining with which note or kind of note they resonate most powerfully. In another series of experiments, instead of analyzing the vocal sounds as above mentioned, Helmholtz endeavoured to produce them *synthetically*, by accompanying a given fundamental note with its several harmonics. This was accomplished by a system of tuning-forks, arranged in harmonic series, which could be thrown into vibration at will in various order. Thus the fundamental note of the first tuning-fork, resembling the vowel *u*, the vowel sound or musical colour *o* was produced if the harmonics 2 were powerfully, and 3 and 4 were weakly, sounded; *e* was produced by the 3rd octave resonating powerfully with the fundamental note, the 2 harmonic note moderately, and the 4 and 5 harmonics feebly, and so on for the other vowel sounds. When two notes are simultaneously sounded, of which one is higher than the other, if the higher note be some multiple of the lower, being produced by 2, 3, 4, or 6 times as many vibrations, harmony is produced; but if the two sounds do not stand in such relation to each other, interference phenomena are pro-

* "Die Lehre von den Ton-empfindungen als physiologische Grundlage für die Theorie der Musik," Braunschweig, 1862.

† It must be borne in mind that the *German* pronunciation of the vowels is here implied.

duced, producing alternate augmentation and diminution of the sound, which are perceived as 'beats.' The number of the beats is of course always equal to the difference in the number of vibrations of the two sounds Thus, if one note has thirty-three vibrations in a second, and another has thirty-four, one beat will be heard every second. If the lower note has sixty-six and the higher sixty-eight vibrations in the second, there will be two beats in the second, and so on. The slighter the difference between the two notes, the more infrequent will be the beats. If a considerable interval of time intervene between two beats, they are perceived to be distinct; but if this occur more rapidly, they produce a painful sensation of discord, which reaches its maximum when there are thirty-three beats in one second, which occurs when the number of vibrations of one note is 528 and of the other 495 per second. Beyond this number the sensation of discord diminishes.—From what has been stated above it appears that the power which we possess of distinguishing the characters belonging to similar notes produced by different instruments, is due to a kind of analysis being performed by the ear, similar to that effected by the wires of the piano; and we shall see that it is not unreasonable to attribute this function especially to the branches of the auditory nerve distributed upon the lamina spiralis of the cochlea. It may be said, indeed, to have received direct confirmation from the observations of Hensen* upon the auditory hairs on the free surface of a Decapod Crustacean (Mysis). These were seen under the microscope to vibrate in certain groups corresponding with the special note sounded in their vicinity. In the case of the human ear a very effective 'damping apparatus' must exist, since through the greater part of the musical scale a trill of ten alternate notes in the second can be distinctly differentiated, which would be confused if the sensation of each note persisted much longer than the sound itself.

600. The essential part of an Organ of Hearing is obviously a nerve endowed with the peculiar property of receiving sonorous undulations, and of transmitting their effects to the Sensorium. This nerve is spread out over the surface of a delicate membrane which lines the Vestibule and its prolongations; and this membrane encloses a fluid, which is the medium whereby the sonorous vibrations received through the external ear are communicated to the nerve.† We learn from an examination of the comparative

* "Zeits. f. wiss. Zoologie," Band xiii.; and "Kieler Institut.," 1869.

J. Horbaczewski (Wiener, "Acad. Sitz.," Band lxxi. p. 312) finds that in the sheep the

structure of the auditory apparatus in the lower animals, and from the study of its development in the higher, that the part which, being most constantly present, and being also the earliest in its development, may be considered as the most essential, is the simple *Vestibular* cavity; which exists where there are no vestiges either of Semicircular Canals, of Cochlea, or of Tympanic apparatus. Such a condition presents itself in some of the higher Invertebrata and in the lowest Fishes; but as we ascend the Vertebrate series, we find the semicircular canals growing out (as it were) of the Vestibule in Fishes, a Tympanic apparatus superadded in Reptiles, and a Cochlea first acquiring a more than rudimentary development in the class of Birds, although only presenting in Mammalia that characteristic form from which it derives its name.* In regard to the mode in which the ultimate subdivisions of the Auditory nerve are distributed upon the lining membrane of the labyrinth, the observations of Rüdinger, Urban Pritchard, and others have demonstrated that the area of distribution of the auditory nerve in the vestibule and semicircular canals is limited to five spots of yellowish colour, visible respectively in the sacculus, the utriculus, and the three ampullæ. In the latter the area of distribution is raised into a kind of ridge or crest (crista acustica of Schultze), whilst in the sacculus and utriculus it is merely an oval spot, which has received the name of the *macula acustica*. At these spots the membranous labyrinth is firmly adherent by a layer of dense connective tissue to the bony wall, not being separated from it by the perilymph. The membrane presents three layers: an external layer of loose connective tissue; a denser layer, named the tunica propria; and lastly, a single layer of epithelial cells. At the macula the loose outer layer is lost, becoming blended with the periosteum, which in many animals here present branched pigment cells. The tunica propria remains unchanged. The tesselated cells increase in thickness, becoming first cuboid and then columnar, and finally over the surface of the macula becoming changed into nerve epithelium. The arrangement of the nerve epithelium presents the following peculiarities. (See Fig. 277.) There is a row of two alternating forms of elongated cells, bordered by a distinct cuticular membrane, and each having a superficial and a deep nucleus. One of these forms is named by Dr. Pritchard the "thorn cell," and the other the "bristle cell." The *thorn cells* have a fusiform body, containing an oval nucleus; a tapering cilium passes upwards from the cell body and projects through an opening in the cuticular membrane; the lower tapering extremity of the body passing downwards again expands, and encloses a second nucleus. The *bristle cells* have a triangular body, containing an oval nucleus; the base of the cell is intimately connected with the cuticular membrane, and from this base passes upwards a single narrow cilium or bristle, having parallel and non-tapering borders. The apex of the body is prolonged downwards, and has a second enlargement, containing a second oval nucleus, usually situated at a different level from that of the corresponding enlargement of the thorn cell. The cuticular membrane is thick, and serves to keep the cell-elements in

vestibular and cochlear nerves are quite distinct from each other at their origin; the fibres of the cochlear nerve are always much finer than those of the vestibular. In the sheep the distribution of the two nerves is sharply limited to the parts after which they are named, but they are much less so in man and the horse. In man the various roots form a common trunk which in the first instance divides into a nerve for the vestibule, and a nerve for the cochlea; the latter, however, is not distributed exclusively to the cochlea, but gives off a fine branch which runs in the recessus cochlearis to the vestibular end of the ductus cochlearis, and through the macula cribrosa quarta to the septum of the two sacculi contained in the vestibule.

* For a more detailed sketch of the Comparative Anatomy of the Organ of Hearing, see the Author's "Principles of Comparative Physiology," §§ 711–714.

place. As it resembles the reticulate membrane of the organ of Corti, it may also be distinguished by the same name—the *membrana reticularis*. Towards the margin of the macula the cells and their various parts elongate, and pass by insensible gradations into the columnar form of the epithelial cells which surround it. Near the centre of the macula, the upper nucleus and surrounding protoplasm of the bristle cells gradually diminish and are ultimately lost, the cell being represented by a trabecula from the membrana reticularis tapering towards its second or lower nucleus. The bristle remains after the upper protoplasmic mass has disappeared, but eventually this also is lost. The trunk and branches of the vestibular division of the portio mollis contains large fusiform bipolar ganglion cells corresponding to those of the ganglion spirale of the cochlea. On arriving at the membrana propria, the nerve fibres lose their white substance and enter the nerve epithelium without it. They here form a plexus around the deep layer of nuclei, and some of the filaments may be traced directly or indirectly into the ciliated cells. Covering the acoustic spot is the 'otolith mass,' a soft mass of cuticular tissue into which the cilia project. It is analogous to the membrana tectoria of the cochlea. The otoliths are fixed by this mass, and are chiefly contained in its outer portion. The structure of the cochlea has been materially elucidated by the extraordinarily minute and delicate dissections of Corti,* Pritchard, and others. It presents two chambers in section, an upper or scala vestibuli (*SV*, Fig. 278), and a lower or scala tympani (*ST*, Fig. 278), separated from each other by the lamina spiralis. The scala vestibuli is subdivided by the membrane of Reissner (*R*) into the scala vestibuli proper and the canalis cochleæ (*CC*). The proximal part of the lamina spiralis is composed of a bony plate, united on both sides with periosteum. It terminates externally or peripherally by a grooved border, formed of a modification of connective tissue, the upper toothed edge of which is named the *limbus*. Beyond the attachment of the membrane of Reissner, the lamina spiralis is continued to the opposite wall of the cochlea by the *membrana basilaris*, which is prolonged from the lower lip of the limbus, and it is on this membrane that the organ of Corti is situated. The organ of Corti, which is the essential part of cochlea and is represented in Fig. 279,† is situated partly on the lower lip of the limbus or terminal portion of the bony lamina spiralis and partly on the membrana basilaris. It is bounded on both sides by epithelium. It consists of :—1. The rods of Corti; 2. The ciliated or hair cells; 3. Certain nuclear cells; 4. The supporting cells; 5. The membrana reticularis; and 6. The membrana tectoria. The rods of Corti are arranged in two rows, an inner and an outer, with their upper extremities in close contact, but separated by a considerable interval below, so that the two rows sloping towards each other form the roof of a triangular tunnel. The foot of the inner rod stands on the lower lip of the limbus, and that of the outer on the membrana basilaris.

† From a drawing by Urban Pritchard in the "Proceed. Roy. Soc.," No. 168, 1876.

The outer surface of the head of the inner rod is hollowed for the reception of the head of the outer rod, and a long process is given off which runs outwards. On either side of the rods are situated various cells; above, and closely adherent to them, is the *membrana reticularis*, and above this is the thick *membrana tectoria*. The length of the rods is graduated, and ranges from 1-150th of an inch at the apex of the spiral to 1-500th inch at its base, the length of the outer rods increasing more rapidly than that of the inner. The *hair cells* are very delicate, columnar in form, with large round nuclei and nucleoli; the rest of their contents is finely granular. From each of their flat summits a row of four bristles or cilia project. There are four rows of hair cells—one (*e*, Fig. 279) situated internally to the rods, the other three (*f*) externally to them. The lower ends of the hair cells are evenly rounded off, and the summits are attached to the membrana reticularis, through the rounded apertures of which the bristles project. The *nuclear* cells have no cell-walls, and are directly connected with nerve filaments. They are found first on the lower lip of the sulcus internal to the rods, in a mass of three irregular layers constituting the 'granular layer' of Waldeyer; secondly, arranged in three or four rows below the level of the outer hair cells, constituting the 'cells of Deiters;' thirdly, there is one in each lower angle of the triangular tunnel formed by the rods of Corti; and lastly, there are one or two scattered about. The '*supporting cells*' of Hensen form the outer boundary of the organ. They are oval or columnar in form, and Pritchard describes one or two similar cells forming the inner boundary of the organ, and names them the inner supporting cells. They form a link between the hair cells and the epithelium. The *membrana reticularis* is composed of a fibrous network, which, on the inner side of the rods, presents one row of regular circular openings, through which the bristles of the inner hair cells project. Over the rods it presents long meshes, and over the outer hair cells there are two forms of meshes—the one elongated, called a *phalanx*, the other circular, called an *annulus*, so arranged that each phalanx is surrounded by four annuli. Through the annuli the bristles of the outer hair cells project. Connected with the membrana reticularis are three rows of fibrous cords, situated on the outer side of each row of the outer hair cells. These trabeculæ pass down to the membrana basilaris. The *membrana tectoria*, or membrane of Corti, is a mucous mass secreted from the epithelial cells, and therefore soft in the fresh state. It commences at the attachment of the membrane of Reissner to the limbus, and passes over the teeth of the limbus as a layer of equal thickness. Then becoming much thicker, it covers the organ, and gradually tapers off externally into the thin general layer which lines the rest of the ductus cochleæ. The bristles of the hair cells penetrate into this mass. The organ of Corti is not found at the two

extremities of the lamina spiralis. The whole organ and its chief component parts, as the rods of Corti and hair cells, enlarge in proceeding from base to apex. The cochlear nerve in the substance of the modiolus, in passing upwards, gives off branches at right angles, which traverse a spiral ganglionic mass, the ganglion spirale, and then enter the lamina spiralis. This ganglion is situated in the lamina at the base, and gradually becoming more central in position, is found entirely in the modiolus at the apex; its cells are bipolar and fusiform, averaging $\frac{1}{1000}$ of an inch in man and most mammals, but are much larger in the porpoise, averaging $\frac{1}{600}$ inch. The nerve-fibres run in bundles, which form a plexus, to the end of the lower lip of the limbus, where they perforate its upper surface, and, losing their dark borders, reach the organ of Corti. The filaments are now divided into two groups—an inner, passing to the parts internal to the rods, and an outer, passing to the opposite side of those bodies. The inner principally enter and appear to terminate in the adjacent mass of nuclear cells (the granular layer of Waldeyer); one large filament, passing through one of the nuclear cells, goes to the inner hair cell and enters its lower extremity. The outer group may be divided into three sets, which all pass between the rods and traverse the triangular tunnel. The upper filament passes along the roof of the tunnel, and on reaching the other side of the outer rod traverses a nuclear cell, and then passes on to the first of the outer hair cells. The middle filament traverses the centre of the tunnel and enters the same nuclear cell, besides sending a branch downwards to another of the nuclear cells. The third or lower filament runs along the floor of the tunnel, being connected with the two nuclear cells in the lower angles of it; on the outer side of the rods this filament enters the nuclear cell, which has received the descending branch from the middle filament: and this cell, again, is connected with the first cell of Deiters by another filament. Filaments in the form of festoons connect the hair cells with each other, and analogous nervous connections are found between the cells of Deiters. A highly educated musical ear is able, according to Weber, to distinguish a sixty-fourth of a semitone, and as in each of the seven octaves which constitute the limits of hearing there are twelve semitones, the total number of intervals perceptible by a cultivated ear is 5,376. But the number of the arches of Corti is estimated by Kölliker at 3,000 (3,500 outer rods, 5,250 inner rods, Pritchard), with at least two radial fibres for each arch. The number of radial fibres is therefore more than sufficient to enable the keyboard of the cochlea to respond by a special cord to each of the sounds that experience has demonstrated to constitute the scale of the most highly-endowed musicians.*

601. In order to gain any definite idea of the uses of different parts of the Ear, it is necessary to bear in mind that sounds may be propagated amongst solid or fluid bodies in three ways; by *reciprocation*, by *resonance*, and by *conduction*.—1. Vibrations of *reciprocation* are excited in a sounding body, when it is capable of yielding a musical tone of definite pitch, and another body of the same pitch is made to sound near it. Thus if two strings of the same length and tension be placed alongside of each other, and one of them be sounded with a violin-bow, the other will be thrown into reciprocal vibration; or if the same tone be produced near the string in any other manner, as by a flute or a tuning-fork, the same effect will result.—2. Vibrations of *resonance* are of somewhat the same character; but they occur when a sounding body is placed in connection with any other, of which one or more parts may be thrown into reciprocal vibration; even though the tone of the whole be different, or it be not capable of producing a definite

* See M. Duval, "Nouveau Dictionnaire de Médecine," t. xxv. p. 452.

tone at all. This is the case, for example, when a tuning-fork in vibration is placed upon a sound-board; for even though the whole board have no definite fundamental note, it will divide itself into a number of parts, which will reciprocate the original sound, so as greatly to increase its intensity; and the same sound-board will act equally well for tuning-forks of several different degrees of pitch. When a smaller body is used for resonance, however, it is essential that there should be a relation between its fundamental note

and that of the sonorous body; otherwise no distinct resonance is produced. Thus, if a tuning-fork in vibration be held over a column of air in a tube, of such a length that the same note would be given by its vibration, its sound will be reciprocated. And if it be held over a pipe, the column of air in which is a multiple of this, the column will divide itself into that number of shorter parts, each of which will reciprocate the original sound, and the total action will be one of resonance. But if the length of the pipe bear no such correspondence with the note sounded by the tuning-fork, no resonance is given by the column of air it contains.—3. Vibrations of *conduction* are the only ones by which sounds can strictly be said to be propagated: these are distinguishable into various kinds, into which it is not requisite here to inquire. It should be remarked, however, that all media, fluid, liquid, or solid, are capable of transmitting sound in this manner; a vacuum being the only space through which it cannot pass. The transmission is usually much more rapid through solid bodies than through liquid; and through liquid than through gaseous. The greatest diminution in the intensity of sound is usually perceived when a change takes place in the medium through which it is propagated, especially from the aëriform to the liquid.

602. The detailed application of these principles has been most elaborately worked out by Professor Müller; and the following statement is little more than an abstract of the results of his experimental investigations; of which the first series bears specially on the case of those animals which, living immersed in water, receive the sonorous undulations through that medium. The labyrinth of such as possess a distinct organ of hearing, is either entirely enclosed within the bones of the head, as in the Cephalopoda and in the Cyclostome and Osseous Fishes; or, its cavity being prolonged to the surface

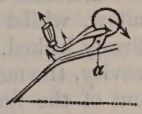
of the body, it is there brought into communication with the conducting medium by means of a membrane, besides receiving the vibrations through the medium of the solids of the body, as is the case in Cartilaginous Fishes and Crustacea:—I. Sonorous vibrations, excited in water, are imparted with considerable intensity to solid bodies.—II. Sonorous vibrations of solid bodies are communicated with greater intensity to other solid bodies brought in contact with them than to water; but with much greater intensity to water than to atmospheric air.—III. Sonorous vibrations are communicated from air to water with great difficulty, this difficulty very much exceeding that with which they are propagated from one part of the air to another; but their transition from air to water is much facilitated by the intervention of a lax membrane extended between them.—IV. Sonorous vibrations are not only imparted from water to solid bodies with definite surfaces which are in contact with the water, but are also returned with increased intensity by these bodies to the water; so that the sound is heard loudly in the vicinity of those bodies, in situations where, if it had its origin in the conducting power of the water alone, it would be faint.—V. Sonorous undulations, propagated through water, are partially reflected by the surfaces of solid bodies.—VI. Thin membranes conduct sound in water without any loss of its intensity, whether they be tense or lax.—VII. When sonorous vibrations are communicated from water to air enclosed in membranes or solid bodies, a considerable increase in the intensity of the sound is produced, by the resonance of the air thus circumscribed.—VIII. A body of air enclosed in a membrane, and surrounded by water, also increases the intensity of the sound by resonance, when the sonorous undulations are communicated to it by a solid body.

603. Animals living in air are nearly always provided with an opening into the vestibule, the *fenestra ovalis*, covered by a thin membrane; and generally with a *Tympanic apparatus* also. The following experimental results bear upon the manner in which the Ear of such animals is affected by sound.—IX. Sonorous undulations, in passing from air directly into water, suffer a considerable diminution in their strength; while, on the contrary, if a tense membrane exist between the air and the water, the sonorous undulations are communicated from the former to the latter medium with great intensity.—X. The sonorous vibrations are also communicated without any perceptible loss of intensity from the air to the water, when, to the membrane forming the medium of communication, there is attached a short solid body, which occupies the greater part of its surface, and is alone in contact with the water.—XI. A small solid body, fixed in an opening by means of a border of membrane, so as to be moveable, communicates sonorous vibrations from air on one side to water or the fluid of the labyrinth on the other, much better than solid media not so constructed. But the propagation of sound to the fluid is rendered much more perfect if the solid conductor, thus occupying the opening, is by its other end fixed to the middle of the tense membrane which has atmospheric air on both sides.—The fact stated in IX. is evidently one of great importance in the physiology of hearing; and fully explains the nature of the process in those animals which receive the sonorous vibrations through air, but which have no tympanic apparatus. In X. we have the elucidation of the action of the fenestra ovalis, and of the moveable plate of the stapes which occupies it, in animals living in air but destitute of tympanic apparatus; this is naturally the case in many Amphibia; and it may happen as the result of disease in the Human subject. In XI. we have a very interesting demonstration of the purpose and action of the tympanum, in the more perfect forms of the auditory apparatus.—We are now prepared to inquire, in somewhat more

of detail, into the actions of the different parts of this apparatus; and it will be better to commence with those of the *Middle* and *Internal Ear*, the accessory organs being afterwards considered.

604. The *Membrana Tympani* consists of three layers; an *external* one continuous with the cutis of the external meatus, and consisting of dermoid tissue with a covering of epidermic cells; an *internal*, which is extremely thin, continuous in like manner with the mucous membrane lining the tympanic cavity, and also composed of dermoid tissue and epithelium; and a *middle* layer, which, according to Mr. Toynbee,* may be separated into two distinct laminæ whose fibres run in contrary directions, those of the external layer (which is the stronger of the two) *radiating* from the malleus towards the peripheral ring to which they are attached, whilst those of the internal are *annular*. The fibres of which these laminæ are composed appear to be tendinous; and the membrane as a whole is almost inextensible. Mr. Toynbee points out the existence of a tubular ligament, enclosing the tendon of the tensor tympani muscle; and considers that the membrane is maintained by this ligament in a state of moderate tension, the assistance of the muscle being only required to augment this.—The membrane is usually inserted so obliquely that the plane of the two forms an angle of 125°–138° opening downwards. Each is funnel-shaped, the base opening outwards, the sides having an inclination of 125° to each other; the apex of the funnel is attached near the centre to the handle of the malleus. Bounafont† considers that a very oblique position of the membrana tympani is a vice of conformation, and his observations made upon a large number of distinguished musicians have satisfied him that in those whose ears are highly developed or sensitive, the tympanum is placed nearly vertically, its whole surface thus presenting itself for the reception of sounds. The function of the *Membrana Tympani* seems obviously to be the reception of sonorous undulations from the air, in such a manner that it may be thrown by them into a reciprocal vibration, which is communicated to the chain of bones, and, as is shown in the accompanying little diagram, through them to the membrane of the fenestra ovalis. Helmholtz has shown that the curvature of the membrana tympani, whilst it diminishes the amplitude of the vibrations, increases their force. In its usual state, this membrane is scarcely on the stretch; and this is found by experiment to be, for a small membrane, the best condition for the propagation of ordinary undulations. This is easily rendered sensible in one's own person; for an increased tension may be given to the membrana tympani either by holding the breath and forcing air into the Eustachian tube, so as to distend it from within, or by exhausting the cavity, so as to cause the external air to make increased pressure upon it; and in either case the hearing is immediately found to become indistinct. It is observed, however, that grave and acute sounds are not equally affected by this action; for the experimenter renders himself deaf to grave sounds, whilst acute sounds are heard even more distinctly than before. This fact is readily understood by referring to the laws of Acoustics already mentioned.‡ The greater the tension to which the membrana tympani is subjected, the more acute will be its fundamental tone; and as no proper reciprocation can take place in it to any sound *lower* than its fundamental tone, its power of repeating perfectly the vibrations proper to the deeper notes will

Fig. 280.



* "Philosophical Transactions," 1851. See also Moldenhaver, "Entwicklung des Mittleren und äussern Gehörgangs." † "Maladies des Oreilles," 1873, p. 278.

‡ See the Experiments of Schapringer ("Wien. Akad. Sitz.-ber.," Band lxii. 1870), who possessed the faculty of voluntarily contracting his tensor tympani.

diminish. The nearer a sound approaches to the fundamental note proper to the tense membrane, the more distinctly will it be heard. On the other hand, when the membrane is in its naturally relaxed condition, its fundamental note is very low, and it is capable of repeating a much greater variety of sounds; for, when it receives undulations of a higher tone than those to which the whole membrane would reciprocate, it divides itself into distinct segments of vibration, which are separated by lines of rest; and every one of these reciprocates the sound,* at the same time rendering it more intense by multiplication (§ 601). These facts enable us to understand the influence of the *tensor tympani* muscle in augmenting the tension of the membrane, and thus enabling it to vibrate in reciprocation to sounds having a great variety of fundamental notes. It appears to be antagonized by the *stapedius*, the contraction of which seems to diminish the tension of the membrana tympani, and to take off pressure from the fluid of the labyrinth. These two muscles conjointly may be considered to regulate the transmission of sonorous undulations to the fluid of the internal sac, preventing it from being too violently affected by loud sounds, in the same manner that the iris regulates the admission of light to the eye (§ 575); and the analogy extends also to their nervous supply, the stapedius being excited to action by a branch of the Facial, whilst the tensor tympani receives its nerves from the Optic ganglion.† They are probably put into conjoint action when we are *listening* for faint sounds, so as to bring the tympanum into the state of tension best adapted to reciprocate them: whilst by a like preparation, the concussive effects of a loud sound that is *anticipated*, are more effectually moderated than when it strikes the ear without warning. It is probably owing to an imperfect action of these muscles, that some persons are deaf to grave sounds, whilst they readily hear the more acute. Helmholtz‡ observes, that by the transference of the vibrations of the tympanum to the much smaller membrane of the fenestra ovalis, mechanical power is gained for the establishment of vibrations in the comparatively incompressible fluid of the labyrinth. He observes also that the inferior aspects of the articular surfaces of the malleus and incus are furnished with small teeth, so arranged that when the malleus moves outwards the articular surfaces easily separate as far as the somewhat loose capsule will allow, whilst when the malleus moves inwards these two bones become firmly locked. The result of this is, that when air is blown into the tympanic cavity, the membrana tympani can move outwards without dragging the stapes out of the fenestra ovalis. Neither the integrity of the membrana tympani

* This is very easily proved by experiment on a membrane stretched over a resonant cavity; for if light sand be strewed upon it, and a strong musical tone be produced in its vicinity, the membrane will immediately be set in vibration, not as a whole (unless its fundamental note be in unison with that sounded), but in different segments, of which every one reciprocates the sound; from the vibrating parts the sand will be violently thrown off, but it will settle on the intermediate lines of rest, which are known as the *nodal* lines, forming a variety of curious figures. See also Donders on the sound colours of the vowels in Donders and Berlius, "Archiv f. d. Holland. Beiträge zur Natur und Heilkunde," Band iii. p. 446. By means of a modification of Scott's form of König's phonautograph, Donders obtained very beautiful pictures or series of curves, representing complicated vibrations, not only of the vocals, but also of the notes produced by the passage of these into consonants, of the sound colours of various musical instruments, and of various notes—all of which present curves of appropriate form. See also Tyndall's work "On Sound," 1867, for a full résumé of all recent researches, and Squire on 'The Quality of Musical Sounds,' "Quart. Journ. of Sci.," 1865, p. 600.

† See Mr. C. Brooke in "Lancet," 1843, p. 380; and Mr. Toynbee in "Brit. and For. Med.-Chir. Rev.," vol. xi. p. 235.

‡ 'Ueber die Mechanik der Gehörknöchenchen,' Pflüger's "Archiv," 1868. See Humphry and Turner's "Journal of Anatomy," vol. iii. 1868, p. 219; also Buck, "New York Med. Journ.," June, 1874.

nor of the chain of ossicles is essential for hearing. It is sufficient that the stapes, and the membrane occupying the fenestra ovalis should be uninjured. All clinical observation shows that the detachment of the stapes, and the rupture of the membrane of the fenestra ovalis, or the ankylosis of the stapes to the margins of the opening rendering it immovable, abolishes hearing so far as this is dependent on the vibrations of the outer air.*

605. The uses of the *Tympanic Cavity* are very obvious. One of its purposes is to render the vibrations of the membrane quite free; and the other, to isolate the chain of bones in such a manner as to prevent their vibrations from being weakened by diffusion through the surrounding solid parts. As to the objects of the *Eustachian Tube*, opinions have been much divided. Many of these opinions, however,—such as the one most commonly entertained, that it serves the same purpose as the hole in an ordinary drum, removing an impediment to the free vibration of the membrane that would be offered by the complete enclosure of the air within,—are at once negatived by the fact, which seems to have been demonstrated by Mr. Toynbee and Dr. Jago,† that the guttural orifice of the tube is usually *closed*, being only opened during the act of swallowing.‡ The principal object of the Eustachian tube (which is always found where there is a tympanic cavity) seems to be the maintenance of equilibrium between the air within the tympanum and the external air. Dr. Jago indeed holds that the normally closed condition is a provision against the ingress of aërial undulations from the throat, which, if admitted, would threaten the membrana tympani with incessant oscillations, and that as the moment seized for bringing the tympanum into communication with the fauces must be one in which there can be no respiratory current, the period selected is the instant of swallowing, at which instant there is a compulsory suspension of respiration; so that neither shouting, singing, whistling, nor coughing can be performed.§ It also has the office of conveying-away mucus secreted in the cavity of the tympanum, by means of the vibratile cilia which clothe its lining membrane; and the deafness consequent on occlusion of this tube, is in part explicable by the accumulation which then takes place in the cavity. From what has been stated, it is evident that sonorous undulations in the air will be propagated to the fluid contained in the labyrinth—through the tympanum, the chain of bones,‖ and

* The increase in the resonance of the voice, and the greater distinctness with which a tuning-fork is heard when the external auditory meatus is plugged with the finger or with wax, is attributable in part to the slight condensation of the air in the meatus that is thus produced (Gellé, "Soc. de Biologie," 1877; "Tribune Medicale," 1877, p. 67), and in part to the obstacle to the escape outwards of the sonorous vibrations (Hinton).

† See his very interesting essays in the "Med.-Chir. Review," 1867, pp. 175 and 496.

‡ Loc. cit., and "Proceedings of the Royal Society," 1852.

§ Lucæ ("Archiv f. Ohrenheilk.," Band iii. p. 186) maintains that exchange of air in the tympanum takes place during the ordinary acts of respiration, and that it is *not* limited to the instant of swallowing. See Zuckerkandl, 'Zur Anat. u. Physiol. der Tuba Eustachiana,' "Monatssch. f. Ohrenheilk.," Dec. 1873, and Knapp's "Archives of Ophth. and Otol.," 1874, vol. iv. No. 1, p. 126. Poorten, "Monats. f. Ohren. Heilkund," 1874, p. 27, observed a case in which the Eustachian tube was kept patent by cicatrices, and in which the patient experienced a very disagreeable resonance of his own voice.

‖ For papers showing that sounds are chiefly conducted through the bones of the tympanum, see J. Jago, in "Proceedings of Royal Society," 1857–59, vol. ix. p. 134; and J. Toynbee, in idem, 1859–60, vol. x. p. 32. See also on this point Dr. Gustav Brunnen on 'The Connection between the Ossicles of Hearing,' in Knapp's "Archives of Ophthalmology and Otology," vol. iii. No. 2, p. 145, and Burnett, "Monthly Journal of Aural Surgery," July, 1871; Politzer, "Archiv f. Ohrenheilk.," Band iv. Heft 1. Buck, however (Hinton's 'Report on Otology,' "Med.-Chir. Rev.," April, 1873, p. 489), found on measuring with a micrometer the little lines into which starch granules scattered over the ossicula are thrown, that the vibrations of the malleus are twice as large as those of the incus, and four times as large as

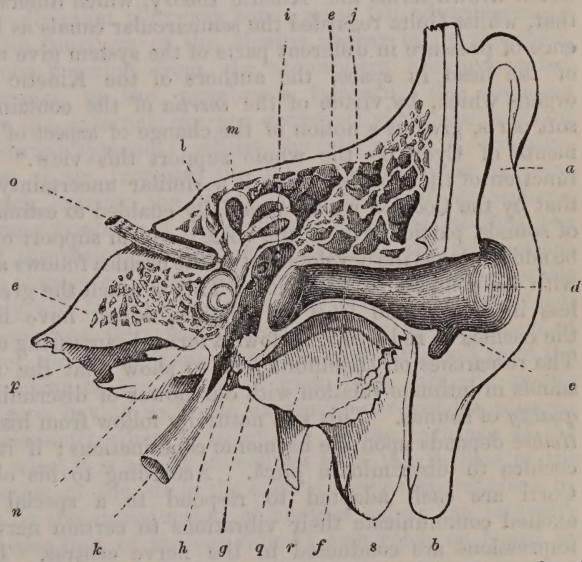
the membrane of the *fenestra ovalis* to which the stapes is attached—without any loss, but rather an increase of intensity. It is of great importance, as Dr. Jago has shown, that the external surface of the membrana tympani should be clean and free from moisture, since if it be rendered moist the power of hearing is immediately lessened; and since its inner surface is continually moist, an additional argument is furnished for the view that sonorous undulations are chiefly conveyed through the ossicula, and not through the air contained in the tympanum. Why water should be chosen as the medium through which the impression is to be made upon the nerve, it is impossible for us to say with anything like certainty, in our present state of ignorance, as to the physical character of that impression. But the problem being to communicate to water the sonorous undulations of air, the experimental results already detailed satisfactorily prove that—whilst this may be accomplished, in a degree sufficient for the wants of the inferior animals, by the simple interposition of a membrane between the air and the fluid—the tympanic apparatus of the higher classes is most admirably adapted for this purpose. The fenestra ovalis is not, however, the only channel of communication between the tympanum and the labyrinth; for there is in most animals a second aperture, the *fenestra rotunda*, leading into the cochlea, and simply covered with a membrane. It is generally supposed that, the labyrinth being filled with a nearly incompressible fluid, this second aperture is necessary to allow the free vibration of that fluid, the membrane of the fenestra rotunda being made to bulge-out, as that of the fenestra ovalis is pushed-in. It may be easily shown by experiment, however, as well as by reference to comparative anatomy, that no such contrivance is necessary; for sonorous undulations may be excited in a non-elastic fluid, completely enclosed within solid walls at every part, except where these are replaced by the membrane through which the vibrations are propagated; and this is precisely the condition, not only of Invertebrate animals, but even of Frogs; in which last a tympanic apparatus exists, without a second orifice into the labyrinth. Moreover it is certain that the vibrations of the air in the cavity of the tympanum must of themselves act upon the membrane of the fenestra rotunda; and this is perhaps the most direct manner in which the fluid in the cochlea will be affected, although it will ultimately be thrown into much more powerful action, by the transmission of vibrations from the vestibule. For it has been satisfactorily determined by experiment that vibrations are transmitted with very much greater intensity to water, when a tense membrane, and a chain of insulated solid bodies capable of free movement, are successively the conducting media, than when the media of communication between the vibrating air and the water are the same tense membrane, air, and a second membrane:—or, to apply this fact to the organ of hearing, the same vibrations of the air act upon the fluid of the labyrinth with much greater intensity, through the medium of the chain

those of the stapes; hence the intensity of the sound waves appears to undergo diminution on their passage from the membrana tympani to the labyrinth. Politzer employed an instrument he named the Tympanograph, fixing fine filaments of glass to each of the bones and recording their movements on a revolving drum. His experiments showed that the amplitude of the vibrations of the several bones was equal, and that, contrary to what might have been expected, the interrupted nature of the chain did not diminish the intensity of the sound waves. Mr. Brooke's observation is also worthy of notice, that, inasmuch as the rapidity of conduction of sound differs considerably in solids and aëriform fluids, if sound were conducted by both means to the labyrinth, confusion would result. The views of Muller, admitting waves of condensation and rarefaction, are supported, in part at least, by Hensen and Schmidekan ("Untersuch. d. Kinder. Instituts," 1869) and Henke ("Zeits. f. rat. Med.," Band xxxi.), who fastened glass threads to the ossicula, and observed great variation in the amplitude of the vibrations, which were sometimes vertical and sometimes transverse.

of auditory bones and the fenestra ovalis, than through the medium of the air of the tympanum and the membrane closing the fenestra rotunda, which last, it is maintained by Dr. Jago, has little if any influence in the transmission of sounds to the internal Ear.—The fenestra rotunda is not to be considered as having any peculiar relation with the cochlea; since, in the Turtle tribe, the former exists without the latter.

606. It is obviously in the *Labyrinth* as a whole, that the sonorous vibrations are brought to bear upon the Auditory nerve spread out to receive them. In regard to the special functions of particular parts of the labyrinth, however, no certainty can be said to exist. The membrane which lines its cavities not only contains a liquid (the *endo-lymph*, *Scarpa's tumour*), but is also separated from the osseous wall by another collection of liquid, the *peri-lymph* or *liquor Cotunnii*; so that it is suspended, as it were, in a liquid which bathes both its surfaces. In the cavity of the Vestibule, which is subdivided by a membranous partition into two, are small round masses of concretionary particles, collectively named *otoconia*, or ear-powder; these are obviously the rudiments of the *otoliths*, or ear-stones, whose presence, in animals with a less perfect auditory apparatus, seems needful to intensify the undulations. —It was formerly supposed that the *Semicircular Canals* had for their peculiar function, to receive the impressions by which we distinguish the *direction* of sounds; and it is certainly a powerful argument in support of this view, that, in almost every instance in which these parts exist at all, they hold the same relative positions as in Man, their three planes being nearly at right angles to one another; but it is now no longer held, because it can be easily shown that the direction of sounds cannot be estimated except by two or more simultaneous or consecutive observations. If a sound of moderate intensity be made at a point equidistant from the two ears, we are unable to judge of its position unless we are aided by the visual sense—and the difficulty of indicating accurately the position of a cricket or deathtic, is well known. The curious movements witnessed by M. Flourens* after section of one or more of these canals (§ 480),

Fig. 281.



Vertical Section of the *Human Ear*, the internal portions on an enlarged scale:—*a*, *b*, *c*, external ear; *d*, entrance to auditory canal, *f*; *e*, *e*, petrous portion of temporal bone; *g*, membrana tympani; *h*, cavity of the tympanum, the chain of bones being removed; *i*, openings from this cavity into the cells, *j*, excavated in the bone; on the side opposite the membrana tympani are seen the fenestra ovalis and rotunda; *k*, Eustachian tube; *l*, vestibule; *m*, semicircular canals; *n*, cochlea; *o*, auditory nerve; *p*, canal for carotid artery; *q*, part of glenoid fossa; *r*, styloid process; *s*, mastoid process.

* See Cyon's 'Researches on the Ear,' in "Nature," 1878, Oct. 10, with Crum Brown's criticisms upon them.

to which reference has already been made, have led to another theory of their use. Flourens observed that section of a membranous canal was always followed by movements of the head or even of the body of the animal in the direction of the divided canal, and hinted that they were concerned in the co-ordination of movements. This suggestion was elaborated by Goltz into what has been termed the statical theory, namely—that the termination of the nerves in the ampullæ, may be supposed to be stimulated by pressure or by stretching. The endo-lymph necessarily presses most upon that part of the wall of the canal which is situated at the lowest point, and each position of the head will correspond to a particular distribution of pressure, and therefore, to a particular form of nerve stimulation. We have thus a special sensation corresponding to each position of the head. The importance of a knowledge of the position of the head and control over its movements in preserving the equilibrium of the body was shown by Goltz, who fixed the head of a pigeon in an unnatural position, when it was found to be incapable of flying, and walked with difficulty. Mach, Breuer, and Brown have advanced a theory which Crum Brown terms the 'Kinetic' theory, which differs from that of Goltz, in that, whilst Goltz regarded the semicircular canals as organs which by difference of pressure in different parts of the system give us a notion of the aspect of the head in space, the authors of the Kinetic theory regard them as organs which, by virtue of the *inertia* of the contained liquid and movable soft parts, give us a notion of the change of aspect of the head. The experiments of Cyon on the whole support this view.* Regarding the special function of the *Cochlea*, there is a similar uncertainty. It has been surmised that by the Cochlea we are especially enabled to estimate the *pitch* and quality of sounds, particularly of the voice; and in support of this idea the fact may be adduced that the development of the cochlea follows a very similar proportion with the compass of the voice. This is much the greatest in the Mammalia; less in Birds; and least in Reptiles, which have little true vocal power: the cochlea is reduced to its lowest form, disappearing entirely in the Amphibia. The researches of Helmholtz tend to show that the function of the cochlea stands in intimate relation with our power of discriminating differences in the *quality* of sounds. This will naturally follow from his demonstration that the *timbre* depends upon the harmonic combinations; if it be the function of the cochlea to discriminate *pitch*. According to his observations, the rods of Corti are each adapted to respond to a special tone, and when thus excited communicate their vibrations to certain nerve fibres, by which the impressions are conducted to the nerve centres. The individual branches of the auditory nerve are probably only capable of distinguishing simple, pendulum-like vibrations, but, as already stated (§ 599), all ordinary sounds are compound in their nature, the fundamental note being accompanied by harmonics; these throw corresponding fibres into vibration, and produce an impression which may be likened to a colour. The analogy which exists between the power of distinguishing *colours* and that of discriminating musical *tones* has long been recognized; and whilst we find that some persons are endowed with the latter, which is commonly known as a 'musical ear,' in a degree that renders it a source of great discomfort to them (since every discordant sound is a positive torment), others are altogether destitute of it—the deficiency being very analogous to the 'colour-blindness' formerly described. It is not a little curious that the two defects are occasionally

* Though he records an important one that is opposed to it, namely, that rabbits, after complete division of the auditory nerve, presented after rotation the same symptoms of vertigo as were exhibited by normal rabbits.

co-existent in the same individual.* The chief objection to Helmholtz's theory is that there are no rods in the cochlea of Birds. Hensen suggests that the radial fibres of the membrana basilaris are primarily thrown into vibration, and it is possible that the hairs of the hair cells, being of various length, may also respond to particular notes.

607. We have now to consider the functions of the accessory parts—the *External Ear*, and the *Meatus*. The Cartilage of the external ear may propagate sonorous vibrations in two ways; by reflection, and by conduction. In reflection, the concha is the most important part, since it directs the reflected undulations towards the tragus, whence they are thrown into the auditory passage. The other inequalities of the external ear cannot promote hearing by reflection; and the purpose of the extension of its cartilage is evidently to receive the sonorous vibrations from the air, and to conduct them to its source of attachment. In this point of view the inequalities become of importance; for those elevations and depressions upon which the undulations fall perpendicularly, will be affected by them in the most intense degree; and in consequence of the varied form and position of these inequalities, sonorous undulations, in whatever direction they may come, must fall advantageously upon some of them.—The functions of the Meatus appear to be threefold. The sonorous undulations entering from the atmosphere are propagated directly, without dispersion, to the membrana tympani: the sonorous undulations received on the external ear are conveyed along the walls of the meatus to the membrani tympani: whilst the air which it contains, like all insulated masses of air, increases the intensity of sounds by resonance. That in ordinary hearing, the direct transmission of atmospheric vibrations to the membrana tympani is the principal means of exciting the reciprocal vibrations of the latter, is sufficiently evident; the undulations which directly enter the passage will pass straight on to the membrane; while those that enter obliquely will be reflected from side to side, and at last will fall obliquely on the membrane, thus perhaps contributing to the notion of direction. The power of the lining of the meatus to conduct sound from the external ear, is made evident by the fact that, when both ears are closely stopped, the sound of a pipe having its lower extremity covered by a membrane, is heard more distinctly when it is applied to the cartilage of the external ear itself, than when it is placed in contact with the surface of the head. The resonant action of the air in the tube is easily demonstrated by lengthening the passage by the introduction of another tube; the intensity of external sounds, and also that of the individual's own voice, as heard by himself, is then much increased.

608. Many facts prove, however, that the fluid of the Labyrinth may be thrown into vibration in other ways than by the Tympanic apparatus. Thus in Osseous Fishes, it is only by the vibrations transmitted through the bones of the head, that hearing can take place. There are many persons, again, who can distinctly hear sounds which are thus transmitted to them; although, through some imperfection of the tympanic apparatus, they are almost insensible to those which they receive in the ordinary way. It is evident, where this is the case, that the nerve must be in a state fully capable of functional activity; and on the other hand, where sounds cannot thus be perceived, there will be good reason to believe that the nerve is diseased. Urbantschitsch† finds that there are three deaf-spots in each ear, or spots in which a vibrating

* See a collection of such cases, by Dr. Pliny Earle, in "Amer. Journ. of Med. Sci.," vol. xxxv. See also Ladovsky, "Archiv f. Mik. Anat." Band xxxiii. p. 497.

† "Centralblatt f. d. Med. Wiss.," 1872, No. 3.

tuning-fork passed in front of the ear is not heard. The two chief areas have the form of two little triangles, one of which extends forwards and upwards, the other backwards and upwards.

609. The power of distinguishing the *direction* of sounds appears to be, in Man at least, for the most part acquired by habit; for it is sometime before the infant seems to know anything of the direction of noises which attract his attention. Our judgment as to this point is probably assisted, in most cases, by a difference in the intensity of the sensations received through the two ears respectively; but since we have a certain power of appreciating direction when one ear alone is used, this power must depend upon an exercise of perceptive discrimination (which is probably acquired, rather than intuitive) in regard to the impressions which we receive through its means; and it has been already mentioned that the Semicircular canals (§ 606) appear to furnish the instrumentality by which our minds are enabled to take cognizance of such differences.—The idea of the *distance* of the sonorous body is another acquired perception, depending principally upon the loudness or faintness of the sound, when we have no other indications to guide us. In this respect there is a great similarity between the perception of the distance of an object, through the Eye by its size, and through the Ear by the intensity of its sound. When we are acquainted with the usual intensity of its sound, we can judge of its distance; and *vice versâ*, when we know its distance, we can at once form an idea of its real strength of tone from that with which our ears are impressed. In this manner the mind may be affected with corresponding deceptions through both senses: for as, in the Phantasmagoria, the figure being gradually diminished while its distance remains the same, it appears to the spectators to recede (the illusion being more complete if its brightness be at the same time diminished); so the effect of a distant full military band gradually approaching may be alike given by a corresponding *crescendo* of concealed instruments. It is upon the complete imitation of the conditions which govern our ideas of the intensity and direction, as well as of the character, of sounds, that the deceptions of the Ventriloquist are founded. A very curious instance of the degree in which our auditory interpretation is affected by other sense perceptions is afforded by the 'Ghost' exhibition which has recently been so popular; for it is scarcely possible to avoid referring to the place where they *seem* to be made, sounds which are really produced elsewhere.

610. The Auditory sense, like the visual, may vary considerably among different individuals, both as regards its general acuteness, and as respects its discriminative power for particular classes of impressions. Much depends upon the *habit of attention* to its indications; and thus it comes to pass, that the power of hearing very faint sounds and of recognizing their source becomes augmented to a wonderful degree in those individuals who are obliged to trust to the knowledge thus acquired for the direction of their own actions; whilst, in like manner, the power of distinguishing slight differences in the pitch of sounds may be so cultivated (where it is not congenitally deficient) as to attain an intensity that seems very extraordinary to those who have not accustomed themselves to listen for them. The general cultivation of this sense is perhaps most remarkable in blind persons, who have enabled themselves, by reliance upon it, to walk about freely, even in the crowded thoroughfares of the metropolis; and who are not only able to judge of the habits of individuals whom they meet by the sound of their footsteps (at once recognizing, for instance, the footstep of a policeman on duty), but can even tell when they are passing a stationary object (such as a lamp-post, provided it be as high as the ear or nearly so, by the reverberation of the sound of

their own footsteps, and can discriminate between a lamp-post and a man standing still in the position of one, by the same means.* The effect of habitual attention in increasing the discriminative power for impressions of one particular kind, is perhaps best seen in the ability which is possessed by certain Conductors of orchestral performances, to detect the slightest departure from time or pitch in the sound of any one of (perhaps) a hundred instruments that are simultaneously sounding, and to fix without hesitation upon the faulty instrumentalist. Seebeck, indeed, affirms that accomplished musicians can detect a difference in pitch between two sounds which only differ by 1-1200th in the number of their vibrations.† According to the researches of MM. Renz and Wolff,‡ our faculty of estimating differences in the *intensity* of sounds is much less perfect. When the intensities of two sounds are to one another as 7 to 10, the difference can be distinguished, but not when they are in the relation of 9 to 10. The advantage resulting from the simultaneous employment of the two ears in distinguishing minute differences in the intensity and pitch of sounds, is well shown in the experiment suggested by M. Weber, of holding two watches in the hand before one ear, when it will be found that the successive sounds can be distinctly heard, though they cannot be distinguished one from the other, whilst if one be held in front of each ear the two sounds can be clearly discriminated.

611. Facts of much interest have been ascertained, some of which have been already alluded to (478), in regard to an occasional difference in the rapidity of the perception of sensory impressions received through the Eye and through the Ear respectively. These facts are the result of comparisons made amongst different Astronomical observers, who may be watching the same visual phenomenon, and 'timing' their observations by the same clock: for it has been remarked, that some persons see the same occurrence a third or even a half of a second *earlier* than others. There is no reason to suppose from this, however, that there is any difference in the rate of transmission of the sensory impressions in the two nerves. The fact seems rather to be, that the Sensorium does not readily perceive two impressions of different kinds with equal distinctness; and that, when several such impressions are made on the senses at the same time, the mind takes cognizance of one only, or perceives them in succession. When, therefore, both sight and hearing are directed simultaneously to two objects, the communication of the impression through one sense will necessarily precede that made by the other. The interval between the two sensations is greater in some persons than in others; for some can receive and be conscious of many impressions, seemingly at the same moment; whilst in others a perceptible space must elapse. The 'personal equation' of each observer in an Observatory has, therefore, to be determined and allowed for.§

* See the account of a blind boot-lace-seller given by Mr. H. Mayhew in his "London Labour and the London Poor," vol. i. p. 402.

† See Ludwig, "Physiologie," vol. i. p. 380; and Béclard, "Physiol.," 1862, p. 1858.

‡ "Archiv f. Phys. Heilk.," 1856.

§ In all the best Observatories, an arrangement is now made for recording observations which supersedes the necessity of timing them by simultaneous attention to the clock. The observer who is watching the transit of a star (for example) across the meridian, simply presses a button at the moment when he witnesses its contact with the cross-wire. This pressure breaks an electric circuit, which is so connected with a chronometer as to stop it instantaneously, and thus automatically to record the precise time of the phenomenon. Since this plan has been adopted, it has been found that the "personal equation" nearly or altogether disappears; thus confirming the view given above as to its dependence on the distraction of the attention between the two objects of perception. For interesting papers on the subject of this paragraph, see Mach, 'On the Sense of Time in the Ear,' Moleschott's "Unters," Band x. 1866, Heft 2. Also Mach, 'On the Accommodation of the Ear,' in idem, p. 201.

612. Amongst other important offices of the sense of Hearing is that of supplying the sensations by which the Voice is regulated. It is well known that those who are born entirely deaf, are also dumb; that is, they do not spontaneously or imitatively form articulate sounds, though not the least defect may exist in their organs of voice. Hence it appears that the vocal muscles are usually guided in their action by the sensations received through the Ears, in the same manner as other muscles are guided by the sensations received through themselves; but when the former are deficient, the action of the vocal muscles may be guided by the latter (§ 496).—That the perceptions obtained by the auditory nerve should be capable of being more quickly perceived and registered than those received through the optic is not surprising, since the course of the former is much shorter than that of the latter. The following Table gives the results of several observers in regard to the physiological time of the several senses of sight, hearing, and touch; or in other words the whole term occupied between the occurrence of an event and its registration :—

	For vision.	For hearing.	For common sensation.
Hirsch . . .	0·2	0·149	0·182 hand.
Hankel . . .	0·2057	0·1505	0·1548 ,,
Donders . . .	0·188	0·18	0·154 neck.
Wittich* . .	0·194	0·182	0·1301 forehead.

By subtracting the physiological time for auditory impressions from those for optical impressions, it appears that the rapidity of the conduction of sensory impulses is comparatively slow. On the highest estimate not exceeding 7·35 metres per second, and on the lowest amounting to only 1·068 metres per second.

The Measure of Sensations.—The observations made by Weber and others on the several senses, have led to the establishment by Fechner of a psycho-physical law† applicable to the quantitative sensations of temperature, pressure, muscular exertion, sound, light, and of fatigue. At first sight it would seem impossible to measure a sensation, but inasmuch as the excitation of any nerve which leads to sensation is caused by external or physical conditions which we can vary or quantitatively determine, we possess in this a means of measuring sensations. Thus, if a weight of half an ounce be held in the hand, and another half ounce be added, a difference is instantly felt; but the addition of half an ounce to twenty pounds is not appreciated. The same is true of light and sound. It would hence appear that for an excitation to be felt, it must be proportionately more feeble as the excitation to which it is added is feeble, and stronger in proportion to the strength of the original or primary excitation. Hence the conclusion may be drawn that the intensity of a sensation increases, not directly in proportion to the intensity of the excitation that produces it, but in some other ratio. Now it may be asked, what proportion does the increase in the intensity of the sensation bear to the increase in the intensity of the stimulus? And in order to acquire this knowledge, three methods of experimentation have been adopted, named by Fechner respectively the method of the *smallest perceptible differences*, the method of *true and false estimates*, and the method of *mean error*. The *first method* consists in this:—Two weights, A and B, are to be compared. If they are nearly alike, they may be judged to be equal; if the difference be considerable it will easily be recognized. If the difference d between A and B be gradually increased or gradually diminished, a point will be arrived at when the difference is only just discernible, and the smaller the difference perceptible, the more acute is the sensibility of the subject. The *second method* consists in taking two weights, the difference between which is so small that an error in judgment is possible. In proportion as the difference increases, the number of accurate conclusions will augment at the expense of the inaccurate ones. If the total number of experiments be 100, and the number of true estimates be 70, we have the

---

† Fechner, "Elemente der Psychophysik." 2 vols. Leipsic, 1860. Delbœuf, "Recherches Théoriques et Expérimentales sur la Mesure des Sensations," Bruxelles, 1873. Ribot, 'La Psychologie Physiologique en Allemagne,' in "La Rev. Scient.," No. 24, 1874. This section is chiefly drawn from Wundt, "Physiologie," 1873.

proportion $\frac{70}{100}$ established by the comparison of the two weights A and B. Now suppose a weight *a* to be given, we seek to determine the weight *b*, which compared with *a* will give the same proportion of $\frac{70}{100}$. Cases of indecision must be placed half to the account of the true and half to the account of the false estimate. The *third method* consists in taking a weight, A, exactly determined by balance, and it is sought by the judgment alone to fix on another weight which is judged equal to the first. In general the second weight differs from the first by a quantity, *d*, which is small in proportion to the acuteness of the sensibility of the subject. This experiment is frequently repeated, the positive and negative errors added, the signs being neglected. The total is divided by the number of trials, and the mean error is thus obtained. By the employment of one or other of these methods the following results are obtained :—

Sensation of Weight.—The hand is extended and supported, the eyes are bandaged, and successive weights, as a drachm, an ounce, a pound, &c., are placed upon it. On each weight various small additional weights are placed till a distinct difference is perceived. The results of numerous experiments by the first method have shown that a very simple relation is maintained—viz., that whatever may be the weight originally placed on the hand, it requires an addition of one-third of that weight to enable a distinct difference to be perceived.

Sensation of Muscular Effort.—This is a much more delicate means of estimating differences of weight than the foregoing, since not only does the sense of pressure, but the sense of muscular effort guide the judgment; and experiments have shown that an additional weight of 6-100th can be detected—*i.e.*, a weight of 6 grains added to 100 grains, or of 60 grains to 1000 is perceptible.

The *Sensation of Temperature* seems to follow the same law as that of simple pressure without muscular exertion, an addition of one-third being requisite to be perceived. In regard to light, photometrical experiments have shown that the intensity of a candle or other source of light must be increased 1-100th in order that the increase should be perceptible. For the sensation of sound, the increase or diminution must be equal to one-third. Renz and Wolff found that for two sounds to be clearly distinguished, they must be in the relation of 100 : 72. The proportion given by Volkmann is 4 : 3, which equal 100 : 75.

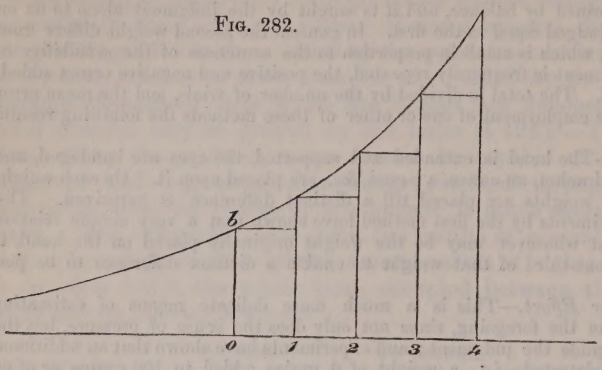
From all this it would appear that if S represent the value of the minimum perceptible sensation, the second possible sensation would be for tactile impressions $S+\frac{1}{3}$; for muscular effort, $S+\frac{1}{17}$; for temperature, $S+\frac{1}{3}$; for light, $S+\frac{1}{100}$; for sound, $S+\frac{1}{3}$; and the results of numerous experiments are as follow :—

Constant proportionals.	Perceptible minimum.
Touch $\frac{1}{3}$	Pressure of 0·002 grm. to 0·05 grm., according to the region of the body experimented on. (Aubert.)
Muscular effort $\frac{1}{17}$ . .	Contraction of the internal rectus of the eye to the extent of 0·004 mm.
Temperature $\frac{1}{3}$ . . .	(The heat of the skin being taken at 18°·4 Cent.) $\frac{1}{8}$° Cent. (? $\frac{1}{10}$, Fechner.)
Sound $\frac{1}{3}$	Ball of cork weighing 0·001 grm. falling 0·001 m. on a plate of glass, the ear being at a distance of 91 millimeters, $3\frac{3}{4}$ inches. (Schafhäutl.)
Light $\frac{1}{100}$.	Illumination of black velvet by a candle at a distance of 8 feet 7 inches. (Volkmann.)

In seeking to find a law which shall express the general relation of excitation and of sensation, it is to be noted that we possess a knowledge of the two necessary elements—namely, the measure of the constant proportional and the measure of the smallest perceptible sensation. The first supplies the unit for dividing the standard into equal parts, the second serves to graduate it, since it determines the zero and renders it fit for use. This may be understood by reference to the following Figure :—In a line, ×, of indefinite length, a zero, 0, is noted. This answers to the minimum of sensation. Starting from the point 0, the line × is divided into equal parts, 1, 2, 3, 4, &c., which represent the increments of sensation. From the point 0, a line, 0 *b* of any length is drawn; it represents the minimum stimulus, say the 1-50th of a gramme if sensations of pressure are under consideration. Now, since the constant proportional, that is to say, the smallest perceptible difference $=\frac{1}{3}$ for pressure, a line drawn from the point 1 must equal the line 0 *b* plus $\frac{1}{3}$ of this line; from the point 2 a line equal to the line 1, plus $\frac{1}{3}$ of 1; from the point 3 a line equal to 2, plus $\frac{1}{3}$ of 2; and from the point 4 a line equal to 3, plus $\frac{1}{3}$ of 3. The third added is thus always an increasing quantity, and as the vertical lines have necessarily the same relation to one another as the weights they represent, it is clear that the differences of length between the line 0 and the lines 4, 5, 6, &c., indicate what weight must be employed in order that the perceptible difference should be quadrupled, quintupled, &c. The psycho-physical law which

Fechner has deduced from this is that within certain limits *sensation increases as the logarithms of the stimulus;* in other words, sensations increase as the logarithms, whilst the excitations increase as ordinary numbers. If we represent the stimulus as R and the corresponding sensation as S, while C represents the constant proportional, then $S = C \log. R$ when the minimum stimulus is taken = 1. This psycho-physical law only holds good within a certain limit. Beyond this the sensation increases more and more slowly, and soon a maximum excitation is reached, beyond which the relation between stimulus and sensation no longer obtains.

Fig. 282.



CHAPTER XV.

ON THE STRUCTURE AND FUNCTIONS OF MUSCULAR TISSUE.

1. *Structure of Muscular Tissue.*

613. The capability of executing movements effecting change of place or of form is a power that is so widely distributed through the animal body, that it has been questioned whether every cell or mass of germinal matter does not possess it at some period of its development. The gradual alteration of shape exhibited by the white corpuscles of the blood (§ 174), by the corpuscles of lymph (§154) and pus (§ 324), by the salivary corpuscles (§ 104), and connective tissue (§ 45), and by pigment* (§ 44) and cartilage cells as well as the rhythmical protoplasmic movements observed in the eggs of osseous fishes,† represent, perhaps, the simplest modes in which this power is displayed. The movements presented by the greater number of these cells or corpuscles resemble those performed by the germinal mass of which an Amœba is composed, the form altering from round to oval or guitar shape, and processes being thrust out at various points into which the body of the corpuscle is again drawn, by which a veritable locomotion is effected. The movements occurring in the fission and cleavage of cells appear to belong to the same category. In all these instances the motions are usually slow and interrupted, but are rendered more energetic and lively by warmth and electricity, and are retarded by cold. In Dr. Ransom's experiments, the presence of oxygen in the surrounding medium was found to be requisite for the exercise of the property of the rhythmic contractility possessed by the food yolk, as well as of the fissile contractility of the formative yolk, whilst, on the other hand, the presence of carbonic acid rapidly checked or altogether

* The pigment cells in the skin of the frog appear, from the experiments of Mr. Lister, "Phil. Trans.," 1858, to be in some measure under the influence of the nervous system, and the black particles in them when set free by the rupture of the cell, exhibit remarkable quivering movements, termed Brownian movements.

† W. H. Ransom, M.D., Humphry and Turner's "Journ of Anat. and Physiol.," vol. i. p. 237.

arrested them.* The several movements here alluded to appear to be of the same kind as those observed in the contraction of muscle, only that the power is generally diffused through the whole of the cell or mass of germinal matter, instead of being limited to an organ of definite structure; just as in some of the lower animals the power of perceiving light seems to be diffused through the body, when no distinct organ of vision has as yet been developed.

614. A second kind of movement is presented by the cells of ciliated epithelium (§ 44), which line parts of the respiratory and genito-urinary apparatus in man, and in him appear to have as their office the establishment of currents directed towards the exterior of the body in the fluids covering the surface of these membranes; whilst in animals they frequently constitute important agents in effecting locomotion and in the procurement of food. The cilia of each cell do not vibrate simultaneously but successively, and the vibrations, which are upwards of 700 per minute,† do not appear to be in any way under the control of the nervous system, since they persist long after somatic death. When they have become languid they can be made to recur with vigour for a short time by the addition of a small quantity of a dilute solution of potash or acetic acid. Engelmann‡ has shown that the energy of ciliary movements rises with the temperature up to 40° C. (104° F.), but rapidly diminishes above that temperature, whilst it again increases as the temperature falls. Distilled water first accelerates, then gradually arrests, ciliary movement. The movement can be re-established by the addition of 1·5 per cent. of sodium chloride, stopped by the addition of 5 per cent., and again set in action by the addition of distilled water. The vapours of ether and chloroform first accelerate for a longer or shorter period, and then arrest the movement. Carbonic acid gas soon arrests the movements, but the admission of oxygen gas leads to their renewal,§ and this alternate action may be kept up for two or three times; when they have stopped they can also be renewed by the action of induced currents of electricity.‖ In the hydroid polypes the body is composed of two layers of cells, the outer of which is named the ectoderm and the inner the endoderm. These are separated by an intermediate fibrous layer or mesoderm, which may

§ See Kühne, Schultze's "Archiv," Band ii. 1867, p. 372, and Klein, in Sanderson's "Physiological Handbook," 1873, p. 21.

‖ Bowditch's ('The Force of Ciliary Motion,' "Centralblatt," 1877, p. 118; "Boston Med. and Surg. Journal," 1876, August 10) experiments show that the work done by the ciliated cells is equal to the raising of their own weight 4·253 metres. That of the striped muscular tissue of the heart is 35 times greater. Jeffries Wyman found that a weight of from 1–3 grammes placed on 12 square mm. of the ciliated mucous membrane of the frog was moved 15 mm. in one minute.

easily be shown to be contractile. On macerating the animal in dilute acid, the cells may be isolated, and it then appears that the contractile elements are in reality prolongations of the cells of the ectoderm. These cells therefore consist of two segments, an outer segment, containing a nucleus surrounded with granular protoplasm, and an inner segment which possesses a contractile power. Kleinenberg has applied the term '*neuro-muscular cells*' to these bodies, believing that they represent in its simplest and most rudimentary form the connection between nerve and muscle. The outer part of the cell constitutes an organ of sensation which is not yet differentiated, except in function, from the internal contractile part; and it is noticeable that even in the higher animals the central parts of the nervous system are formed from an involution of the epiblast, and that consequently there is a community of origin between the cells of the integument and those of the nervous system.* Ranvier† states that the cilia are stained yellow with picrocarminate of ammonia and blue with anilin, in these respects resembling the protoplasm of ordinary cells. Between the line of insertion of the cilia and the cell-protoplasm is a disc ('plateau') which covers the whole free surface of the cell, and is rapidly and strongly stained with aniline but not with picrocarminate of ammonia. The disc presents a series of beads, which are the swollen bases of the cilia. The cilia, therefore, perforate the disc and rest on the cell-protoplasm; but Ranvier has been unable to corroborate the assertion of Eberth and Marchi, that they may be traced to the nucleus of the cell.‡ The vibratile motions presented by the spermatozoa appear to be of the same nature as those of ciliated epithelium, and each zooid may be regarded as a cell, provided with a single cilium. Dr. A. Stuart,§ who describes the processes as extending from the base of each cilium to the nucleus and attached extremity of the cell, regards them as extremely fine muscular fibres. Dr. Stuart's observations were made on the cells of the ciliated epithelium of certain species of Eolis. He has counted from 40 to 60 bands in each cell, and describes the nucleus of the cell as being moved hither and thither by their contraction.

Fusiform cells of *Smooth Muscular Fibre*, from the renal vein of Man: *a*, two cells in their natural state, one of them showing the staff-shaped nucleus; *b*, a cell treated with acetic acid, with its nucleus *c* brought strongly into view.

615. Putting aside these cases, however, all the sensible movements of the body are effected by one or other of two forms of tissue to which the term muscular has been applied. The first of these, termed the smooth or unstriped variety of muscle, consists of flattened bands, destitute of sarcolemma, which are composed of long, fusiform cells (Fig. 284), each with an elongated oval nucleus, which become staff-shaped after death.‖ Around the nucleus is a little finely granular protoplasm, which extends for some distance in the axis of the fibre, and which can sometimes be shown to possess

a longitudinal striation;* the length of the cells varies from 1-1125th to 1-50th of an inch, and their breadth from 1-5625th to 1-1125th of an inch. The cells can best be isolated according to Moleschott by maceration in a solution of 35 per cent. of caustic potash.† The nerves distributed to unstriated muscle form a plexus, containing both medullated and non-medullated fibres, and present a few scattered ganglion cells. From this primary plexus a secondary plexus arises, composed of non-medullated tissue alone, with nodal swellings at the points of intersection, and the finest ramifications either run along the side of the muscle elements (Gscheidlen) or penetrate them to reach the nucleus and nucleoli (Arnold). This form of muscular tissue is found in a nearly pure state, unmixed with other tissue, in the nipple, corium, intestinal canal, bladder, prostate, vagina, and in the smaller arteries, veins, and lymphatics; and mingled with much areolar, fibrous, and elastic tissue in the trabeculæ of the spleen and corpora cavernosa, the dartos, the circular fibres of the larger arteries and veins, the urethra, Fallopian tubes and uterus, in the trachea and bronchi, and in the ciliary muscle of the eye, the choroid coat, and the iris. The principal features of the contraction of unstriated muscle may be observed in the uterus of rats and rabbits. In these organs, when exposed, and due precautions in regard to temperature and moisture are attended to, spontaneous contractions, travelling at the rate of about one inch per second, may be seen to occur at intervals of from ten to twenty seconds; mechanical stimulation applied to any point produces two waves of contraction—an ascending or antiperistaltic and a descending or peristaltic; a ligature applied to the middle of the ureter arrests the progress of the spontaneous waves of contraction to the lower segment, which remains motionless, whilst the upper part continues to exhibit the intermittent contractions; an isolated portion of the ureter remains quiescent unless stimulated, when contraction occurs. It is difficult to explain the cause of the movements, but it is probable that they are initiated by the nervous system, the contraction then being propagated from fibre to fibre.

616. The second variety of Muscular tissue presents transverse striæ under the microscope, and occurs in all those muscles that are usually termed "voluntary," though its presence in the heart, rectum, and pharynx shows that it is not limited to these alone.‡ On examining the structure of a striated muscle it is found to be easily separable into coarser or finer *fasciculi* connected by means of areolar tissue, and these on more minute dissection can be shown to consist of transversely striated polygonal *fibres* with three or five angles, having, in Man, an average diameter of 1-400th of an inch. The fibres frequently terminate by free pointed extremities in the muscle, and occasionally divide; at other times they become continuous, either abruptly or by imperceptible gradation with tendinous or strong connective tissue fibres.§ In the case of the heart, the tissue is stated by Eberth‖ and Schweigger-Seidel¶ to be composed of transversely striated oblong cells, often forked at their extremities, and containing one or several nuclei (§ 214),

* Ranvier, "La Système Musculaire," 1880, p. 382.

† Engelmann considers that the disintegration of the fibres into fusiform cells is artificial.

‡ In the Echinodermata, Vermes and Mollusca, Schwalbe ("Archiv f. Mic. Anat.," Band v. 1868, p. 205) has shown that muscular fibres exist which present double oblique striation, or two sets of oblique symmetrical decussating lines.

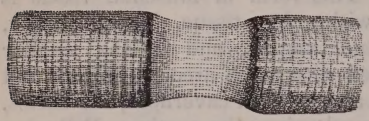
§ As in the tongue, Hyde Salter, in "Cyclop. Anat. and Phys.," vol. iv. p. 1132. Hoyer, however, maintains that in such instances the transparent fibres in which the muscular fibres apparently terminate are in reality contractile. See Reichert's "Archiv," 1859, p. 481.

‖ Virchow's "Archiv," 1866, Band xxxvii. p. 100.

¶ Stricker's "Hum. and Comp. Histology," Syd. Soc. Transl., vol. i. p. 244.

Fig. 118). The divarication of the terminal portions and the occasional presence of lateral processes, give rise to the illusory appearance, described by Skey and others, of anastomoses occurring between the fibres.* The length of the fibres in the Sartorius varies, according to Krause, from one-third of an inch to one inch and a half; whilst, according to Dr. Nicol,† in the small muscles of the hand they are co-equal with the length of the muscle, and in the muscles of the forearm vary from 1-25th of an inch to one inch. During life the fibres of striated muscle appear to be semi-transparent and of soft consistence.‡ After death each fibre can be split either longitudinally into *fibrillæ*, the number of which has been estimated at six or seven hundred, or transversely into a series of disks; the average diameter of the fibrillæ is 1–9400th of an inch in man, and they are bound together by a transparent sheath, the sarcolemma (Fig. 285) § (between which and the contractile substance a distinct layer of protoplasm sometimes exists as in the muscular fibres of the crab). Immediately beneath the sarcolemma (mammals) and sometimes in the interior of the fibre (amphibia, birds, fishes), are 'muscle corpuscles.' These consist of a nucleus with one or two nucleoli, and an investing layer of protoplasm which sends off long processes that communicate with those of other corpuscles, so as to form a delicate network of fibres beneath the sarcolemma. The corpuscles are readily brought into view by the action of acetic acid. According to some observers these are to be regarded as the remains of the original cells from which the muscular fibres were developed; others have regarded them as centres from whence new muscular fibres may originate; others, as the corpuscles of the connective tissue distributed

Fig. 285.



Muscular Fibre broken across, showing the untorn *Sarcolemma* connecting the fragments.

* It is usually stated that no sarcolemma exists around the cardiac muscular fibres. Winkler, however, describes it as being present in the form of an extremely delicate membrane. Reichert's "Archiv," 1867, p. 221.

† Schmidt's "Jahrbücher," Band cxxxii. 1866, p. 148.

‡ Kühne ("Physiol. Chemie," 1868, p. 281; also Marey, "Rev. des Cours Scient.," tome iii. p. 797) observed a Nematoid worm (Myoryctes Weissmannii), move with apparent freedom in the interior of a fibre. The movements of the worm displaced the striæ, which as it passed onward resumed their natural position. Besides this evidence of the semi-fluid nature of the contents of the fibre, it has been found that when a current of electricity is passed through a few muscular fibres, the substance of the muscle accumulates around the negative pole, indicating a certain freedom of movement in the constituent particles.

Sci." vol. xvi. 1876, p. 251.

through the muscle, and therefore as centres of nutrition analogous to the lacunæ of bone; and still more recently it has been maintained that they are in connection with the ultimate terminations of nerves. The exact structure of the fibrillæ is still doubtful. Under high powers of the microscope they appear to consist of alternate rectangular light and dark bands, constituting the "sarcous elements" of Mr. Bowman. The dark bands are thicker than the light ones, and in consequence of their being less easily acted on by dilute hydrochloric acid and gastric juice, can be obtained in a detached or separate state after short exposure to the action of either of these fluids. Brücke has described the dark particles as refracting light doubly (anisotropous), whilst the clear intervening substance is only singly refractile (isotropous).* He regards the dark particles as uniaxial positive crystals, having their axes parallel to the direction of the fibres, and as being composed of minute solid doubly-refracting particles, which he terms *disdiaclasts*. Engelmann† describes each fibre as being, when fresh, almost perfectly transparent and homogeneous, but speedily undergoing a kind of coagulation, which is hastened by the addition of any reagent, and results in the appearance of a series of superimposed disks, varying in their thickness and their action on light. These confer upon the tissue its peculiar striated aspect, and the adjoining Figure (286) exhibits them in a diagramatic form. The column formed by each fibril is, in the first place, divided at regular intervals by septa, *z*, which, as they are at the same level in adjoining fibrils, run across the whole fibre. The septa divide the fibrils into compartments named by Engelmann 'muscle elements,' and by Krause 'muscle caskets,'§ and the contents of each casket are laminated. The *septal* or *intermediate disks* are composed of a homogeneous membrane, which with sharp focussing forms the darkest stria of the fibre; water and various reagents make it granular or beady, though the

The sarcous elements are swollen at their extremities, and at their centres. Magnified 1000 diam.

* See Stricker's "Hum. and Comp. Histology," Syd. Soc. Trans., vol. i. p. 235, 1870. Dr. Martyn (Beale's "Archiv," 1862, p. 227), in examining a fortunate specimen of muscular tissue under a very high power (1,200 linear), observed large and small sarcous elements to occur alternately, as had previously been described by Busk and Huxley (Note to Kölliker's "Man. of Hum. Histology," Syd. Soc. Trans., vol. i. p. 239); the smaller one evidently corresponding to the faint transverse line traversing the clear space long ago perceived and described by Dr. Sharpey and the Author, from careful observation of Mr. Lealand's preparations. Dr. Macnamara ("Med. Times and Gazette") describes the muscular *fibres* of the chameleon when examined with the highest powers ($\frac{1}{50}$) as composed of a sheath of sarcolemma containing two longitudinal flat bands, connected by a spirally wound band, the shadow or the approximation of two coils of which forms the transverse striæ. Between the horizontal bands are *open spaces*, as is shown by their never becoming stained with carmine. M. Rouget (Brown-Séquard's "Journ. de la Physiologie," and "Med.-Chir. Rev.;" see also "Comptes Rendus," 1867, pp. 1128, 1232, and 1276) regards the elementary *fibrilla* of striated muscles as being a spirally twisted ribbon, of which the coils, ordinarily separated from one another or stretched, approximate on the removal of all exciting and nutritive conditions.

§ Muskel-kästchen.

fibre may still retain its contractile power. It is doubly refracting, and its greatest thickness (in Articulata) is 0·0008 mm. It is highly elastic—*i.e.*, is compressed and extended with difficulty. The sarcolemma presents either an annular groove, or an elevation where it is attached to it, and the connection between the two is usually firm. 2. The *isotropal layer* between the septum and the collateral or secondary disk is almost immeasurably thin. 3. The *secondary* or *collateral disk* (*n*), Flögel's 'granule layer,' has a thickness of 0·002 mm. This is usually separated from the anisotropal substance by a thin layer of isotropal substance, but is sometimes fused with it, as can easily be determined by polarized light, the anisotropal substance then appearing much thinner, since the collateral disk presents but feeble indications of double refraction. It adheres less firmly to the sarcolemma than to the septal disk. In breaking a fibre across mechanically, the rupture commonly occurs between the collateral and the transverse disks. In mammals the septal or intermediate and the collateral disks appear to be fused together. 4. The *isotropal layer* between the secondary and transverse disks in Vertebrata has a thickness of 0·001 mm., and in Arthropods of 0·0015. This is very soft, but still not fluid, as Kühne thought. 5. The *layer of anisotropal substance* consisting of two transverse and a median disk (*m*). This layer after the action of many reagents appears to be formed of solid doubly-refracting rod-like elements, the so-called sarcous elements, muscle prisms or rodlets which are imbedded in a softer, singly-refracting amorphous substance. (Fig. 287.) The rods, according to Engelmann, are certainly not preformed elements. The account given by Schäfer differs considerably from the foregoing. He describes a muscular fibre as consisting of a ground substance, appearing at first sight to be composed of a series of alternately dim and bright disks, and of a vast number of minute rod-like particles, to which he applies the term muscle-rods, which are closely arranged side by side with their long axes parallel to the axis of the fibre, so as to form by their juxtaposition as many series as there are disks of dim substance in the fibre. The main part or shaft of each muscle-rod is imbedded in and traverses a disk of dim substance, while the ends which are enlarged into little knobs or heads extend into the bright disks. These little knobs form the line of dots which has long been described as existing in the middle of each bright stripe. When the fibre is somewhat extended this line appears double, owing to the separation of the heads of the two successive series of muscle-rods which meet in the middle of the bright substance. In the state of absolute rest (R, Fig. 288) the rods are uniformly cylindrical without terminal enlargements, and in this case only a longitudinal fibrillation is to be seen in the fibre, all trace of transverse striping having disappeared. In the normal state of slight tension however (P), the rod-heads make their appearance, and with

them the bright substance by which they are surrounded, so that the dim ground substance now presents a transversely striated aspect. In contraction of the muscle the heads of the rods become enlarged at the expense of the shaft, the ends of the several muscle-rods thus approaching one another, and forming, with the heads of the next series of muscle-rods, a dark transverse band crossing the bright stripe. As the contraction proceeds, the dark bands approximate to one another, the bright borders encroach upon the dim stripe, which finally disappears, so that its place is taken by a single transverse bright stripe (c). Contracted muscle consequently shows alternate dark and bright stripes, the former, however, being due to the enlarged juxtaposed extremities of the rods, the light on the other hand being mainly composed of the ground substance which has become accumulated in the intervals between their shafts.* Examined by polarized light, the muscle-rods give indications of being isotropous or singly refracting, whilst the remainder of the fibre is anisotropous. The latter is probably the true contractile part, whilst the rods are merely elastic structures, serving to restore the fibre to its original length. The muscles receive a free supply of blood, especially during action,† the capillary vessels being arranged in oblong meshes ; but their lymphatics are either altogether absent or exceedingly few in number.‡ The mode of termination of the nerves in muscle has recently been the subject of much investigation.§ According to Kühne and Engelmann, the motor nerves divide and subdivide till the fibres run alone or only in bundles of two or three on the outside of the muscular fibres. After a short course, however, they penetrate the sarcolemma, losing at the same time their sheath, which becomes continuous with the sarcolemma, and the white substance of Schwann; whilst the axis-cylinder, dipping in amongst the fibrillæ, terminates in a nerve-plate or disk, which melts by imperceptible gradations into the tissue of the muscle itself. Cohnheim,‖ whilst agreeing with Kühne in admitting the penetration of the sarcolemma by the nerve-fibres, represents these as branching and dividing to a considerable extent. Kölliker, Beale, and Krause,¶ on the

FIG. 290.

M, muscular fibre, surrounded by portions of six others. *a*, Nucleus of the nerve sheath; *b*, nucleus of the sarcolemma; *c*, section of nucleus of terminal plate of nerve; *d*, transverse section of terminal plate, surrounded by granular material; *e*, transverse section of muscle nuclei; *f*, fine fat drops. The angular dark particles are sections of groups of sarcous elements and form Cohnheim's areas; the clear intervening spaces represent the fluid isotropal part of the muscle substance.

* Mr. David Newman ("Journ. of Anat. and Physiol.," vol. xiii. 1879, p. 549) has recently suggested a new theory of contraction of striated muscle, in which he conceives that Krause's compartments contain a plasma, which during a state of rest holds the whole of its combined fat in complete solution, and is doubly refracting, but in the act of contracting the plasma precipitates its fat, which collects in the form of a flattened disk at the centre of the cylinder. The plasma, thus freed from its fat, forms the light band, and is only singly refracting.

other hand, deny the penetration of the sarcolemma by the ultimate branches of the motor nerves, the two former observers describing them as forming a plexus, composed of pale fibres of extraordinary tenuity (1-100,000th of an inch), intermingled with many nuclei lying on and ramifying *over* the fibres. Mayo describes a similar plexus within the sarcolemma, whilst Krause admits the plate, but believes it to be outside the sarcolemma. The three accompanying drawings, Figs. 290–292, will render the views of Kühne, Cohnheim, and Beale intelligible. The proportion of nerve-fibres in the motor nerve trunks to the number of the muscular fibres, in the muscles to which they are distributed, varies considerably.* Tergast finds in the ocular muscles of the Sheep that there is one nerve-fibre to about 6 or 7 muscular fibres. In the ocular muscles of Man there are about 3 nerves to 7 muscular fibres. In the biceps of a young Dog there is one nerve-fibre to 83 muscular fibres; in the sartorius of the same animal 1 to 40-60. In the cutaneous pectoral of the Frog the proportion is 1 : 23–27 (Reichert); in the abductor digiti quinti pedis 1 : 40; in the sartorius 1 : $16\frac{1}{2}$; in the ocular muscles of the same animal, 1 : 10. In the caudal muscles of the Mouse, 1 : 28-29. The presence of sensory nerves in muscle, though much disputed, seems to have been demonstrated by Sachs,† first, by producing reflex convulsions on irritation of the central end

Muscular Fibre, with termination of Motor nerve, from the Gastrocnemius of *Rana esculenta*: —*a*, Terminal pencil of a dark-bordered nerve-fibre; *b*, Intra-muscular naked axis cylinder; *c*, Nucleus of the neurilemma; *d*, Clavate extremities of the nerve; *e*, Muscle-nuclei; *f*, Terminal knob of nerve, with central fibre and vesicular dilatation of the nerve.

of the nerve entering the sartorius in a frog poisoned with strychnia, such convulsions occurring even when the anterior roots of the spinal nerve had been divided; secondly, by showing that after section of the anterior roots of the sciatic plexus, though degeneration of the greater part of the nerve supplying the sartorius occurred, yet that two doubly-contoured fibres remained undegenerated; and, thirdly, by showing that the mode of distribution of the motor and sensory nerve fibres differs, the former dividing dichotomously, and the latter in an arborescent manner.

617. *Chemical Composition of Muscle.*—The muscles of cold-blooded animals are well adapted for chemical investigation on account of the slowness with which they undergo change. If the muscles of such an animal, after the removal of all blood from the tissue by the injection of a very weak solution of common salt, be subjected to pressure, a neutral or weakly alkaline fluid is

* See Tergast, Schultze's "Archiv f. Microscop. Anatomie," Band ix. p. 36.
† "Archiv f. Anat. u. Physiol.," 1874.

obtained, termed "muscle-plasma," which soon undergoes spontaneous coagulation, and separates into two parts—a semi-solid portion termed myosin (§ 55), and a fluid serum, which at ordinary temperatures quickly acquires an acid reaction. In the latter, as obtained from various animals by different chemists, there have been discovered: 1. Various albuminous compounds, and compounds nearly allied to albumin. 2. Ferments, as pepsin (Brücke); and a substance analogous to, if not identical with, ptyalin (Piotrowski), or amylopsin, and a lactic acid producing ferment. 3. A colouring matter similar to, if not identical with, hæmoglobin.* 4. Kreatin (§ 56), and perhaps kreatinin,† hypoxanthin or sarkin, carnin, xanthin, and taurin. 5. Urea, inosinic and uric acids. 6. Sugar, inosit, glycogen, and dextrin. 7. An insomeric modification of lactic acid, termed para- or sarco-lactic acid, acetic, formic, and butyric acids. 8. Salts, which, as obtained from the residue of broth, consist in 100 parts‡ of

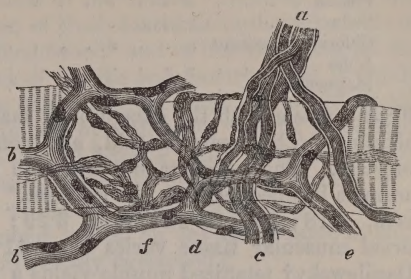
Fig. 292. (After Beale.)



Portion of an Elementary Muscular Fibre from one of the abdominal muscles of the *White Mouse*, with four dark-bordered fibres (*a*) crossing over its surface. A capillary vessel, *b*, is also seen with fine nerve-fibres distributed to it. To avoid confusion, a few only of the transverse markings of the muscle are represented. Two of the dark-bordered nerve-fibres (*c*), pass over the elementary fibre, to be distributed to adjacent fibres. One dark-bordered fibre (over *d*) is lost among several pale nucleated fibres. Pale nucleated fibres are seen ramifying in several places upon the surface of the elementary fibre, but beneath the dark-bordered nerve-fibres and capillaries. It will be observed that a fine fibre, which seems at the upper part of the figure to be but one of the outlines of the tubular membrane of one of the dark-bordered fibres, leaves the dark-bordered fibre and passes to the capillary vessel (over *e*). This arrangement, in which a dark-bordered nerve-fibre distributed to a muscle divides into branches, one of which passes to a vessel, while the other ramifies upon a muscle, is frequent. The capillaries, dark-bordered nerve-fibres, and pale nucleated fibres here represented, can be completely stripped off from the surface of the sarcolemma without tearing that membrane. Of the structures, therefore, represented in this drawing, not one, according to Dr. Beale, after whom it is taken, can lie beneath the sarcolemma. (× 700.)

9. A small proportion of fat. 10. Water, carbonic acid, and oxygen gases; and, lastly, various compounds derived from the tissues which are inseparably united with the muscular tissue, as protagon, proceeding from the nervous, gelatin from the connective, and elastin from the vascular tissue. The composition of muscle as a whole is thus given by Kühne, after Lehmann:—

Water	74·0—80·0
Solid constituents	26·0—20·0
Albuminous substances insoluble in water (myosin, sarcolemma, nuclei, vessels, and elastic fibres)	15·4 —17·7
Gelatin	0·6 — 1·9
Albuminates of soda, coagulating at 113° F.	2·2 — 3·0
Kreatin	0·07— 0·14
Fat	1·5 — 2·30
Lactic acid	1·5 — 2·30

* Lankester, Pflüger's "Archiv," Band iv. p. 315.

† Nawrocki, Fresenius' "Zeits. f. Analyt. Chemie," 1865, p. 330, denies the presence of the latter, or that any conversion of kreatin into kreatinin occurs during exercise.

Magnesia	0·04—0·05

Fresh muscle, with the exception of that of the heart, is either neutral or faintly alkaline. The heart is acid, and contains a little more water than other muscles. The percentage proportion of nitrogen in the flesh of different animals has been shown by Petersen* to vary: thus mutton contains 3·15; veal, 3·18; pork, 3·25; beef, 3·29; and horseflesh, 3·48. Its amount in dried muscular tissue varies from 11·88 to 15·07 per cent. According to Danilewsky† tetanized muscle yields a little more nitrogen to warm alcohol, which dissolves the products of its disintegration, than muscle at rest. Amongst these is lecithin. Muscular tissue, whether living or dead, absorbs oxygen, and eliminates carbonic acid,‡ though more energetically in the former case than in the latter. The specific heat of muscle exceeds that of water, and is higher than that of any known solid or fluid body.§ It is, on the other hand, an exceedingly bad conductor of heat. Glycogen is a constant constituent of muscle, the quantity varying from about one-half to one per cent. It augments when the muscles are kept at rest,‖ and diminishes with exercise, and especially after tetanus. In Rabbits the muscles of the back contain nearly a fourth more than the adductors of the thighs. It diminishes considerably after fasting, but rapidly increases above the normal when much starchy food is taken.¶ It is increased after division of the motor nerves supplying the muscle,** but is diminished after ligature of the arteries.††

618. *Development of Muscular Tissue.*—In Man, according to Mr. Lockhart Clarke,‡‡ Muscular Fibre can first be distinguished about the fourth or fifth week of utero-gestation. In a fœtus of three-fourths of an inch in length, it forms a gelatinous mass consisting of fibres and nuclei imbedded in a semi-fluid granular blastema. In the formation of the fibres, granular processes of condensed blastema extend from the sides or from around the nuclei, which are subsequently bounded by an investing substance in the form of a band or fibre, sometimes plain, but sometimes longitudinally fibrillated. In these bands the transverse striation first makes its appearance, and only subsequently extends through the central band or axis. The muscular fibres vary in size at different parts, and they may sometimes be seen to increase in diameter by the adhesion of fresh nuclei and fresh processes of blastema. A very similar account has been given by Mr. Savory for the Mammalia generally,§§ except that in his observations the nuclei, at first irregularly distributed, were found to arrange themselves with great regularity in single rows, almost in contact with one another, the fibres being formed by the development of two nearly transparent bands enclosing and bounding the rows of nuclei; subsequently the nuclei began to separate from one another, and

ultimately broke up into granules and disappeared. The striation began within the border and gradually extended to the centre. Increase in the size of the fibres was effected by the addition of fresh blastema to the outer side of existing fibres. The observations of Braidwood* and of Eckhard† are, on the whole, confirmatory of the observations of Clarke and Savory; and it would hence appear that the essential features of the process occur not in the nuclei, nor in cells, as was originally maintained by Schwann, but in a material which may be regarded as intercellular substance; and Lockhart Clarke regards even involuntary muscular fibres as by no means the *product* of a nucleated cell, but rather as a kind of cell-formation, presenting at first a nucleus encrusted with blastema, around which an investing sarcous substance representing the cell-wall is subsequently developed.‡

619. The frequently renewed exercise of muscles, by producing a determination of blood towards them, occasions an increase in the nutrition; so that a large amount of new tissue is developed, and the muscles augment in size and vigour. This is true not only of the whole muscular system when equally exercised, but also of any particular set of muscles which is more used than another. Of the former we have an example in those who practice a system of gymnastics adapted to call the various muscles alike into play; and of the latter in the limbs of individuals who follow any calling that habitually requires the exertion of either pair, to the partial exclusion of the other, as the arms of the smith, or the legs of the opera-dancer. But this increased nutrition cannot take place unless an adequate supply of food be afforded; and if the amount of nutritive material be insufficient, the result will be a progressive diminution in the size and power of the muscles, which will manifest itself the more rapidly as the amount of exertion, and consequently the degree of *waste*, is greater. Nor can it be effected if the exercise be incessant, for it is during the intervals of repose that the reparation of the muscular tissue occurs; and the Muscular system, like the Nervous, may be worn out by incessant use. The more violent the action, the longer will be the period of subsequent repose required for the reparation of the tissue; and the longest time will of course be requisite when (as sometimes occurs) the contractility of the muscle is so completely exhausted by excessive stimulation that no new manifestation of it can be excited. It does not appear improbable that there is a provision in *some* Muscles, as the Heart and Respiratory Muscles, by which the nutrition is carried on with unusual activity during the short period of repose which intervenes between two successive contractions. Moreover, the muscular tissue, like all the softer and more decomposable portions of the organized fabric, has a limited term of existence; and hence, even if its contractility be not called into exercise, it undergoes a gradual disintegration so soon as all the nutritive changes of its fibres are completed. This change seems to be a necessary consequence of the high temperature of the bodies of warm-blooded animals; for it does not occur with nearly the same rapidity in cold-blooded animals, nor in the hybernating condition of certain warm-blooded Mammalia; indeed, when the temperature of the body is reduced to within a few degrees of the freezing point, no chemical change seems possible in muscle—its spontaneous decay and its vital activity being alike checked. Now, when a muscle or set of muscles in a warm-blooded animal is reduced to a state of prolonged

* "Med.-Chir. Rev.," 1866, p. 447. † "Zeitsch. f. rat. Med.," Band xxix. p. 55.

‡ Dr. Wilson Fox ("Phil. Trans.," 1865–6) has, however, resuscitated the older view of Lebert, Kölliker, and others, that the fibres of muscle proceed from the cells of the embryo, the contents of which become fibrillated, whilst the cell-wall becomes the sarcolemma.

inactivity, from whatever cause, its supply of blood is diminished, and its spontaneous decay is not compensated by an equally active renewal; so that in time the characters of the structure are changed, and its distinguishing properties are no longer presented. Thus it was found by Dr. John Reid* that in a rabbit, a portion of whose sciatic nerve had been removed on one side, the muscles of that leg were but very feebly excited to contraction by galvanism after the lapse of seven weeks. The change in their nutrition was evident to the eye, and was made equally apparent by the balance. The muscles of the paralyzed limb were much paler, smaller, and softer than the corresponding muscles of the opposite leg, and they scarcely weighed more than half—being only 170 grains, whilst the others were 327 grains. It was found also that a perceptible difference existed in the size of the bones of the leg, even after so short an interval had elapsed; the tibia and fibula of the paralyzed limb weighing only 81 grains, whilst those of the sound limb weighed 89 grains. On examining the muscular fibres with the microscope, it was found that those of the paralyzed leg were considerably smaller than those of the sound limb, presenting a somewhat shrivelled appearance, and that the longitudinal and transverse striæ were much less distinct. So in persons whose lower extremities have been long disused, the muscles first become pale and flabby; their bulk gradually diminishes; their contractile force progressively decreases, and at last departs almost entirely; and their proper structure is replaced by a deposit of fat, in which few or no striated muscular fibres can be detected. But muscles that have for some time remained in this condition may be gradually brought back to their original state by exercise, provided that the feeblest contractility remains; for every action which they can be made to perform determines an augmented flow of blood through the tissue, and gives rise to an improvement in its nutrition, which in its turn increases its contractility, and renders it capable of more vigorous action. This principle is of great importance in the treatment of the various forms of paralysis (especially the hysterical), in which the muscles are thrown out of use by the suspension of the functional power of the nerves; for when the latter have recovered their capacity, the muscles refuse obedience to their stimulation, and can only be brought to act by persevering and judiciously contrived exercise.

620. Muscles exist in two states, the elongated and the contracted; the former is usually termed their state of *rest*, in which they immediately respond to the application of stimuli, whether direct or indirect, by passing into the active state of contraction.† The physical, chemical, and electrical properties of muscles differ considerably in these two states.—In *contraction* the muscles become shorter and thicker, and diminish slightly in volume.‡ Their elasticity

* "Edinb. Monthly Journ. of Med. Science," May, 1841; and "Physiological, Anatomical, and Pathological Researches," p. 10.

† Dr. Radcliffe (see his "Epileptic and other Convulsive Diseases of the Nervous System," 3rd edit. 1860, and his "Lectures on Epilepsy, Pain, and Paralysis," 1864) has, however, adduced many arguments to show that the ordinarily received statement above given should be reversed, and that the state of elongation should be regarded as the really active condition of muscular fibre, in which all its vital properties and peculiarities are most strongly marked; whilst the state of contraction is due to its being left to the influence of the attractive forces inherent in its molecules, the most energetic operation of which is seen in the rigor mortis. According to Lavdovsky ("Centralblatt," 1871, p. 769) the unstriated muscle fibres of Leeches and Worms, when stimulated, first elongate and become attenuated, and then contract and become thickened. The number of successive contractions that can be made to occur per minute in isolated muscle-cells varies from 10–20, which is the ordinary number, to 36–40, which only happens in very lively animals.

‡ Harless, "Abhand. Münch. Akad.," 1862, p. 357. Luigi Fasci, Virchow's "Jahresbericht," 1867, p. 80.

and electrical relations are modified, and heat* and sound are produced. They absorb more oxygen. They give off, as already stated, more carbonic acid. Their reaction changes from neutral or feebly alkaline to acid, which, according to Ranke,† is due to the development of lactic acid. They contain more kreatin, grape sugar, and fat, and less glycogen.‡ From the experiments of Helmholtz,§ which have been corroborated by Ranke, it appears that the muscles of frogs long subjected to the action of an interrupted current of electricity yield from 20 to 24 per cent. less of extractives soluble in water, whilst those soluble in alcohol increase to a corresponding amount; the muscles also respond differently to electrical shocks. In tetanus, the muscles of the extremities, if the blood-current through them be preserved, become more watery (Ranke). This is particularly the case with the heart. The quantity of albumin diminishes, though only to an inconsiderable extent (Helmholtz, Ranke, Nawrocki). The heart in the case of the Dog, in comparison with the muscles of the extremities, contains much less albumin. The heart yields much more warm alcohol and less watery extract than the quiescent, and even than the tetanized muscles of the extremities. The alcoholic extract of tetanized muscle, and especially of the heart, contains more nitrogen than that of quiescent muscle.‖ It is remarkable that highly oxygenated blood, such as is the condition of the blood in apnœa, renders both the nerves and muscles unexcitable.¶

621. Numerous experimenters** have shown that the contraction of muscular tissue is accompanied by the production of a considerable amount of *heat*. Helmholtz found that on tetanizing the muscles of the thigh of a frog by stimulating the spinal cord for two or three minutes, the temperature, as indicated by a thermo-electric apparatus, rose 0·14°–0·18° C. Heidenhain found that each contraction of the gastrocnemius of a frog raised the temperature 0·001°–0·005° C. In warm-blooded animals the heat generated is much greater. Billroth and Fick†† observed a rise of 0°·5 C. or more when tetanus was maintained for ten minutes. The degree of heat developed is dependent upon the tension of the muscle, upon the amount of work done, and upon the condition of freshness or exhaustion of the muscle. With the increase of tension the amount of heat generated is augmented, so that a muscle contracted to the utmost, supposing its excitability and the stimulus to remain the same, develops the maximum of heat; hence the whole amount of heat generated increases with the amount of work done, though a portion

* In rigor mortis (Fick, in "Vierteljahrsch. der Naturf. Gesell. in Zurich," 1867), with Dybkowsky, observed a rise of 0°·05—0°·07 C., and they attribute the rise in temperature sometimes observed in bodies after death to this source, the muscles then becoming rapidly stiff.

†† Wundt, "Physiologie," 1873, p. 536.

is derived from the contraction of the muscle itself. The temperature falls rapidly with increasing exhaustion, and the amount generated is inappreciable to our present means of research before the muscle has quite lost its power of contraction. The gradual increase in temperature, observed when a muscle is tetanized, continues for some time after contraction has ceased; and proceeds, in all probability, partly from the continuance of a more energetic process of oxidation, indicated by the increased production of carbonic acid, and partly from an increased flow of blood through the vessels of the muscle. According to Meyerstein and Thiry, the amount of heat generated is always in proportion to the amount of work done; whilst Heidenhain maintains that the relation between the two is inverse after a certain point has been reached. He notices also that less heat is developed if the muscle be allowed to shorten, and thus to perform work, than if it be prevented from shortening, and this may reasonably be explained on the supposition that during the active alternate contraction and elongation of the fibres the circulation through the vessels is more rapid, so that the heat locally produced is carried off by the blood. Fick* finds that the greatest quantity of heat which 1 gramme of muscle develops in a single contraction is 3·1 mcal.,† which would correspond to the combustion of 0·8 mg. of carbo-hydrate or 0·3 mg. of fat. The mechanical work performed by the muscle corresponds to only a very small part of the heat produced, varying from 1 : 3·5 to 1 : 23·6.—The peculiar *sound* heard during the contraction of striated muscle may be perceived, as suggested by Dr. Wollaston,‡ by placing the tip of the little finger in the ear, and contracting the muscles of the ball of the thumb, or by powerfully exerting the muscles which close the jaw. It resembles the distant rumbling of carriage wheels, or an exceedingly rapid and faint tremulous vibration, which, when well marked, has an almost metallic tone. From various experiments made upon himself and others, Professor Haughton estimates that the number of vibrations varies from 32 and 36 per second. The sound may be readily conceived to depend upon the friction of the elements of the muscle, one upon another, which must thus be perpetually taking place so long as it continues in a state of activity, an explanation that receives support from the observation of Helmholtz, that the pitch of the note may be made to vary by exciting contraction in the muscle with an interrupted current, the shocks of which succeed one another with varying rapidity.—The *amount of shortening* which a muscle will undergo bears a direct relation to the resistance; and by opposing a sufficient resistance, the contractile power of the muscle may be powerfully exerted without any contraction taking place. Under ordinary circumstances the striated muscles do not contract much more than one-third of their length, being restrained by the mechanical arrangements of the bones and joints, and by the antagonistic muscles. But if a long muscle of a frog be removed from the body and powerfully stimulated, it will contract to one-fifth of its original length. The unstriped fibres will contract under favourable circumstances to about one-third of their length.

622. Muscles, whether in the contracted or elongated state, possess a certain amount of *elasticity*. By this term is meant that force by which the particles of any substance, after being approximated to or separated from one another, strive to regain their original position. The elasticity of muscular fibre is small, but remarkably perfect;§ for although it is extended considerably by

* Pflüger's "Archiv," Band xvi. 1878, p. 89.

† Microcalory. The amount of heat required to raise one milligramme of water 1°C.

‡ "Philosoph. Trans.," 1811.

§ The determination of the elasticity of the muscles is attended with some difficulty, since, when stretched by a weight, they yield quickly to a certain degree, and then move slowly to

a light weight, it recovers itself completely on the removal of the extending force.* Like that of India-rubber, it is augmented by heat.† That it is exceedingly small, even during life, is shown, as Mansvelt has observed,‡ by the fact, that in cases of paralysis of the third nerve the pupil is for some days brought quite into the middle of the space between the eyelids solely through the *elastic* contraction of the rectus internus; a proof that its antagonist, in a state of elongation, exercises no force worth speaking of. On appending a small weight to a vertically-suspended fresh muscle, it at first elongates suddenly and considerably (the primary extension), then much more slowly (the secondary extension). On removing the weight, the same phenomena appear in inverse order; a considerable primary, and a more gradual and smaller secondary retraction. With small weights the increase in length is proportional to the weight; with heavier weights a greater proportional weight is required to produce the same amount of extension, as is shown in the following experiment made by Weber§ with the Hyoglossus of a Frog:—

Weight in Grammes successively applied to the Muscle.	Length of the Muscle in Millimetres.	Extension.	
		In Man.	Per Cent.
0·3	24·9	—	—
1·3	30·0	5·1	20
2·3	32·3	2·3	7
3·3	33·4	1·1	3
4·3	34·2	0·8	2
5·3	34·6	0·4	1

Mansvelt, however, deduces as the principal result of his experiments, that living muscle is, at least within certain limits, extended in proportion to the increase of the weight, each fibre elongating about 1 per cent. of its length for each 65th of a grain weight appended to it. According to Wundt, the weight which is required to extend a fresh muscle of 1 square millimetre (1-25th of an inch) sectional area, twice its length, is 2 oz. The importance of the elasticity of the muscles is obvious, for by its means, notwithstanding that the distance between the points of origin and insertion is undergoing constant change, the muscles are kept in a state of constant slight tension, so that no time is lost before contraction begins; moreover, it prevents rupture both in sudden passive extension, and, which is far more important, when the muscle itself shortens, so that contraction is gentle and distributed over a longer time. As a rule, during life the muscles are subjected to strong but brief extension acting upon them when they are in a state of contraction, rather than in a state of relaxation. It would obviously have seriously interfered with their action had a high degree of elasticity been conferred upon them, since antagonistic muscles would have had this, in addition to all other

the true amount, and again, on being released from the weight, they quickly retract to a certain degree, and move slowly to their full extent. This constitutes the "elastische nachwirkung" or "secondary elasticity" of the Germans. This occasions much loss of time, and as the quality of the muscle rapidly changes, materially interferes with comparative experiments.

§ Wagner's "Handwörterbuch," Band iii. p. 54. See also Volkmann, Pflüger's "Archiv," Band vii. 1873, p. 15. Fick, Pflüger's "Archiv," 1871, Band iv. p. 301, finds that the elasticity of muscle varies with each degree of contraction.

resistances, to overcome, before movement could be effected. Weber has shown that the extensibility of muscles increases during contraction. He applied a weight of 115 grains to an elongated muscle. On the addition of another weight of 15½ grains, the amount of extension which took place was about 1–144th of its length; but on repeating the same experiment with a contracted muscle, the extension was as much as 1-79th of its length, showing that the extensibility was greater in the latter case than in the former. The exhaustion of a muscle greatly increases its extensibility up to a certain point, after which it again diminishes. Thus, when a portion of muscle was weighted with 115 grains, its greatest extension occurred when it had been made to contract 43 times; when weighted with 193 grains, after 23 contractions; and lastly, when weighted with 424 grains at the 8th contraction. It was even found that, by appropriate weighting, a muscle on being stimulated to contract might actually become longer instead of shorter.

623. *Electrical Relations of Muscle.*—As we have already seen in the Nerves (§ 426), so in the Muscles it is easy to furnish evidence of electrical disturbance. The conditions of the 'Muscular current' have been made the subject of special investigation by M. du Bois-Reymond; and the following is an outline of the results at which he has arrived, for the due comprehension of which, however, it is requisite that the terms employed by him should be first defined.—The entire muscle being composed of a mass of fibres, having a generally parallel direction, and attached at their extremities to a tendinous structure (which has in itself but little or no electro-motor power, but is a conductor of electricity), it follows that the tendon or tendinous portion of a muscle represents a surface formed by the *bases* of the muscular fibres considered as prisms, which may be designated its *natural transverse section.* On the other hand, the fleshy surface of the muscle, which is formed only by the *sides* of the fibres considered as prisms, may be regarded as the *natural longitudinal section* of the muscle. Again, if a muscle be divided in a direction more or less perpendicular to its fibres, an *artificial transverse section* will be made, whilst if the muscle be torn lengthways in the direction of its fibres, an *artificial longitudinal section* will be made; and these artificial sections show the same electric conditions with their corresponding natural sections. Now, experiments repeated in a great variety of modes demonstrate that *every point in the natural or artificial longitudinal section of a muscle is positive in relation to every part of its transverse section, whether natural or artificial;* and hence a current is passing in the muscle from the transverse to the longitudinal section (Fig. 197). The most powerful influence on the galvanometer is produced when a portion of the surface (or natural longitudinal section) of a muscle is laid upon one of the electrodes, and a portion of the surface formed by cutting the muscle across (or artificial transverse section) is placed against the other. When the two tendinous extremities of a muscle, whose form is symmetrical or nearly so, are placed against the electrodes, the deflection of the needle of the galvanometer is but slight; and the same is the case with two transverse sections taken at equal distances from the two ends of the muscle, and also with two points of the longitudinal section which are equally distant from the middle of its length. But if the two points of the longitudinal section applied to the electrodes be not equally distant from the centre of the muscle, then the point which is nearest to the centre is positive to the one which is nearest to the end; and, in like manner, when the different parts of the transverse section are tested in regard to each other, the points lying nearest the surface of the muscle are found to be positive to those nearest its anterior. The intensity of the current,

however, between any two points in the *same* section—whether transverse or longitudinal—is always incomparably less than that of the currents which are obtained between two points in *different* sections, one in the longitudinal and the other in the transverse. These results may be obtained, not merely with the entire Muscle, but with insulated portions of it; and even, as we are assured by M. du Bois-Reymond, with a single primitive fasciculus. It has been suggested by Hermann that the key to the electrical opposition which exists between the artificial transverse and the artificial longitudinal section is probably to be found in the action of oxygen on the muscular tissue, the surface exposed by the cut being more rapidly acted on, as compared with the longitudinal section, which is protected by more or less fascia, and by the sarcolemma of the fibres. In favour of this view it is to be observed that the more rapidly after removal from the body the electrical relations of the *natural longitudinal* and *artificial* transverse sections, or in other words of the tendon and the surface of the muscle are tested, the slighter is the difference found to exist between them; indeed, if the examination be made sufficiently early, especially if the animal has been kept in the cold, it will be found either that no difference exists between them, or that the tendon and a portion of the muscle near its longitudinal axis are positive in regard to the surface of the muscle.

624. *Negative Variation.*—That a change in the electric state of a Muscle takes place in the act of contraction, had been ascertained by the experiments of Professor Matteucci;* but as he was only able to detect this by the galvanoscopic frog (the galvanometer which he employed not giving unquestionable indications of it), he was not able to determine its nature with accuracy. This has been accomplished, however, by M. du Bois-Reymond; who has shown that during contraction the muscular current is not increased (as supposed by Matteucci), but is diminished, and even reduced to zero. In order to exhibit this phenomenon satisfactorily, it is found advantageous to cause the muscle to contract powerfully or uninterruptedly for as long a time as possible—that is, to *tetanize* it; and this may be effected by acting violently on its nerve by heat, chemical agents, or a rapid succession of electric shocks; or by poisoning the animal with strychnia. In whatever mode the tetanized state is induced, the same result follows—the needle of the galvanometer passes over to the negative side. Ranke† has noticed the remarkable fact that dead muscle is a better conductor of electricity than living, and that the conducting power of muscle exhausted by exercise is also increased. This he attributes to the accumulation of the products of disintegration, and especially to that of lactic acid. Living muscle conducts electricity about three millions times worse than mercury, and fifteen millions times worse than copper.

625. The rapidity with which the mandates of the Will are communicated to and executed by the Muscles is immeasurable; but Helmholtz has shown that if an electric spark, whose duration does not exceed one six- or seven-hundredth of a second, be allowed to strike a portion of fresh muscle, a measurable period, amounting to 1 or 2-100ths of a second, intervenes before the commencement of contraction. This he terms the *period of latent contraction or excitation.* At the commencement of the contraction which succeeds, an instantaneous electrical discharge occurs, lasting less than the 1000th of a second, and comparatively weak, but still probably equivalent to that of the electric organ in fishes.‡ The contraction which then takes place

* See his successive Memoirs in "Phil. Trans.," for 1845, 1847, and 1850.

† "Tetanus," Leipzig, 1865.

‡ See Donders' "Essay on the Constituents of Food," translated by Dr. Moore, Dublin, 1866, p. 14, where it is quoted as the observation of Meissner, and as corroborated by v. Bezold.

is not sudden and complete, but is divisible, according to Klünder,* into four stages, in the first of which the movement of contraction commences and slowly increases; in the second there is great increase in the rapidity of the contraction; the third is the period of maximum rapidity, and in the fourth there is a diminution of the rapidity. The first period can be much protracted by heavy weighting, and the last period is very variable. Klünder gives as the duration of the latent excitation of fresh and lively muscle $\frac{3}{400}$ths of a second, but when exhausted and heavily weighted it rises to $\frac{1}{100}$th of a second; previous extension of the muscle diminishes the duration of the latent excitation, as Helmholtz also found.† The true curve of contraction at its middle portion represents a parabola modified by the elasticity of the muscle. The period of time which elapses from the instant that the stimulus is applied until the contraction is complete, increases generally with the amount of shortening, with the heaviness of the weight, and with the exhaustion of the muscle. In the Frog the entire time occupied in the contraction and subsequent elongation of a muscle is about one-third of a second, of which

Fig. 293.

The vertical line, *a c*, marks the moment of stimulation; *b*, the beginning, *d*, the maximum, and *e*, the end of the contraction of the muscle. The interval between *a* and *b* is known as the "latent period" of the contraction of the muscle. The undulations between *e* when the contraction of the muscle has ceased, and *f*, are believed to be due to the elasticity of the muscle.

	Of a second.
The period of latent excitation amounted to	0·02
„ „ contraction „	0·180
„ „ elongation „	0·105
	·305‡

From the results of various experiments, Helmholtz satisfied himself that to develop their greatest force, muscles require a longer time than when slight efforts only are made.§

626. *Mechanism of Muscular Contraction.*—From the inquiries of Mr. Bowman, it appears that the act of contraction usually commences at the extremities of the fibre; but it frequently occurs also at one or more inter-

* Op. cit., p. 129.

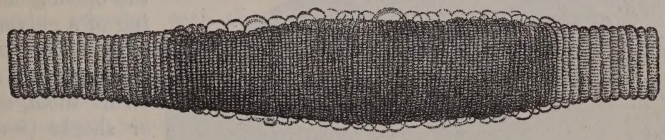
† Ranvier ("Comptes Rendus," lxxvii. p. 1105, and "Archiv. de Physiolog.," t. vi. p. 1) has pointed out various differences between the white and the red muscles of the rabbit, and amongst others, that the period of latent excitation of the white muscles of the rabbit is 1-83rd of a second, whilst for the red muscles it is as much as 1–18th of a second.

‡ See Helmholtz in Müller's "Archiv," 1850, 1852; and Volkmann, in "Leipzig. Berichte Math. Phys. Class.," 1851. Place has more recently ("Nederland. Archief," Band iii. 1867, Heft 2) estimated the period of latent excitation in the muscles of frogs at only 0·005 sec., and he finds the rapidity of propagation of the excitation through muscles to be about one metre per second.

§ For a very minute investigation on this point, see Klünder, 'Ueber den zeitlichen Verlauf der Muskelzuckung,' in the "Arbeiten aus dem Kieler Physiologischen Institut.," 1868, pp. 107–130.

mediate points. The first appearance is a spot more opaque than the rest, caused by the approximation of a few of the dark points of some of the fibrillæ; this spot usually extends in a short time through the whole diameter of the fibre; and the shading caused by the approximation of the transverse striæ increases in intensity. The striæ are found to be two, three, or four times as

Fig. 294.



Muscular Fibre of Dytiscus, showing the *contracted state* in the centre; the striæ approximated; the breadth of the fibre increased; and the sarcolemma raised in bullæ on its surface.

numerous in the contracted as in the uncontracted part, and are also proportionally narrower and more delicate. The line of demarcation between the contracted and uncontracted portions is well defined; but as the process goes on, fresh striæ are absorbed as it were from the latter into the former. The contracted part augments in thickness, but not in a degree commensurate with its diminished length, so that its solid parts lie in smaller compass than before—the fluid which previously intervened between them being pressed out in bullæ under the sarcolemma (Fig. 294). Marey and Aeby have shown that when a muscle is excited by passing a current of electricity through it, every part contracts simultaneously, as proved by the identity in point of time of tracings taken with levers attached to different parts. In like manner, when the nerve supplying a muscle is excited, the whole muscle appears to contract simultaneously, and this is explained by Aeby on the supposition that the contraction commences at the point of entry of each terminal twig of the nerve, and propagates itself away from this point in both directions. As these points of entry are distributed very irregularly in neighbouring fibres, the swelling appears to be uniform throughout. In one of his experiments, a muscle of a frog is taken, the motor nerve of which bifurcates as it enters. One of the divisions is cut, and the main trunk excited. It is then found that that portion of the muscle which is supplied by the intact nerve contracts simultaneously throughout, whilst in the remaining portion a wave is propagated that travels at precisely the same rate as the contraction that occurs when mechanical irritation is applied to a given point of a fresh muscle. The rapidity of this last is given by Aeby,* for the muscles of frogs at about 40 inches per second, Bernstein† estimated it far more highly at nearly 13 feet per second, and quite recently Hermann‡ operating on the muscles of frogs, both with and without curare, gives the rapidity at 2·698 metres per second, or about 9 feet. It is increased by heat and retarded by cold. M. Marey§ has lately shown by means of his delicately constructed registering apparatus, that the contraction of a muscle which follows the application of a sudden stimulus, as of an electric spark, differs remarkably from the contraction

§ See his Lectures on 'Self-registering Apparatus,' in the "Revue des Cours Scientifiques," tom. iii.

induced by a voluntary impulse. In the former instance the contraction is sudden and single, especially if the muscle be quite fresh, becoming slower as the muscle experiences fatigue. This is clearly shown in the following woodcut, which represents the tracing obtained on a rapidly-rotating circular disk from a muscle made to contract by the opening and closing of a galvanic current. Two contractions, or, as M. Marey terms them, impulses or shocks (secousses) are exhibited. One series (o) corresponding to the period of opening of the induced current, the other of closing (C). The line traced at the bottom of the figure by a diapason vibrating 100 times (double vibrations) per second enables the duration of each of the impulses to be estimated. The arrangement of the apparatus is such that the lower lines represent the tracing obtained when the muscle is in the perfectly recent state, whilst the upper ones represent it when more or less exhausted. It will be noticed that for each galvanic shock there is a single instantaneous contraction represented by an elevation with rounded summit, and that the period of ascent corresponding to the period of shortening of the muscle (on the left) is more rapid than the period of descent of the line, the latter corresponding to the period of relaxation. In proportion as the muscle becomes fatigued, three peculiarities may be noticed: the duration of the contraction or shock augments; the period of ascent becomes prolonged, and the height of the wave or amount of shortening of the muscle increases. This last, however, is only transient, since, if the tracings be continued, the wave height diminishes though its width continues to increase. The tracings present the same features whether the excitation be applied to the nerve supplying the muscle, or to the muscle itself. It is very interesting to remark that the phenomena of exhaustion are not produced in the living body within moderate limits, indicating that reparation is constantly taking place. Of all the muscles of the body, the heart alone in its ordinary contraction gives a tracing corresponding to that obtained from a voluntary muscle on the application of an electrical shock—that is to say, the heart constitutes the only instance where each contraction is definite and single, and it presents the same characters in all animals. In all other instances, what is termed a muscular contraction consists of a series of shocks or impulses, as shown in Fig. 296, in which a tracing is shown such as may be obtained from a muscle caused to contract by a voluntary effort, or to which excitations at regular intervals are applied. Here the effects of the successive shocks are in the first instance superadded to one another till a

Fig. 295.

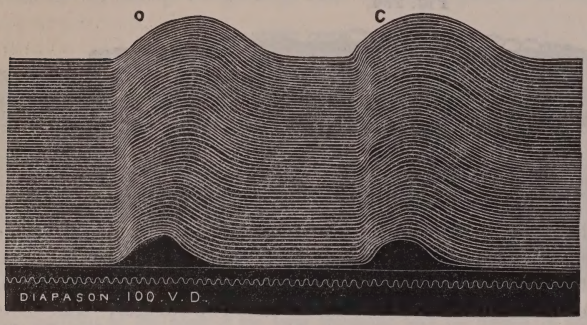

Fig. 296.

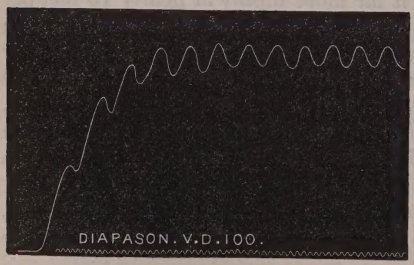

certain degree of contraction is obtained, which remains permanent with that amount of stimulation. If the electrical or mechanical* excitations are made to succeed each other more rapidly (Fig. 297), the successive shocks unite more quickly and completely, and the total contraction is greater in degree. Finally, if the excitations are repeated more than a certain number of times per second, varying with the animal and the state of the muscle, the several shocks fuse completely into one another, and tetanus is produced in which no vibration is perceptible (Fig. 298). The muscles of different animals respond differently to electrical excitation. In the case of the bird,† permanent contraction or tetanus is not produced until more than 75 shocks are communicated in a second, whilst the muscles of a tortoise are tetanized with only three shocks per second. Ranvier‡ found considerable difference in the reaction of the white and red muscles of rabbits to induced electricity. Thus the semi-tendinosus (a red muscle) excited for one-seventh of a second with a current that was interrupted 357 times in a second, passed at once into a state of tetanus (Fig. 298, c) and its myographic tracing exhibited a continuous and uniform elevation. The adductor longus, on the other hand (a pale muscle), stimulated in the same way, showed as many elevations and depressions as there were interruptions of the current (Fig. 297).

Fig. 297.

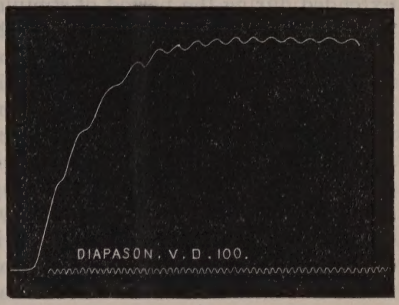

Fig. 298.

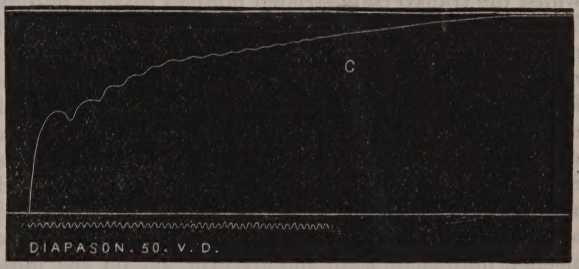

627. The contractility of the muscles may be called into play either directly by stimuli applied to the tissue itself, or indirectly by agents exciting the motor nerves. The contraction which follows in the latter instance is termed by Schiff *neuro-muscular*, and in the striated muscles is sudden, general, and energetic; but when mechanical irritation is directly applied to a muscle, the tissue itself responds to the stimulus, producing what Schiff has termed *idio-muscular* contraction. It may be observed in the manner first described by Dr. Stokes§ by percussing the pectoralis muscle of emaciated patients, or by drawing the back of a knife across a muscle after all signs of irritability on the application of stimuli to the motor nerve have ceased; it then presents itself as a swelling or intumescence a few lines broad and high, but varying with the strength of the blow, lasting for four or five seconds, and slowly disappearing. Kronecker and Stirling‖ found that the red muscles of the rabbit,

* As in Heidenhain's mechanical Tetano-motor, in which a little hammer is set in motion by an electro-magnetic current, and a tetanic condition can be established in the muscles which will last for two minutes or more, till the irritability of the nerve is destroyed.

§ "On Diseases of the Chest," p. 397. ‖ Foster's "Journal of Physiology," vol. i. p. 395.

when stimulated with four shocks per second, passed into incomplete tetanus; and with ten shocks per second into complete tetanus. The pale muscle of the rabbit requires 20-30 shocks per second to be completely tetanized, whilst six induction shocks per second prevent it from becoming completely extended during the period of stimulation. A further phenomenon has been noticed in the same muscles by Auerbach* after an energetic blow; namely, a wave or undulating contraction, proceeding from either side of the local intumescence of Schiff, and propagating itself to the extremity of the muscle at the rate of about eighteen inches per second. The breadth of the waves is about a quarter of an inch at their base, and they gradually die out as they spread from the point struck. It is doubtful whether both of these appearances are not due simply to a prolonged contraction of the muscle, resulting from exhaustion of its contractility at the excited spot. A difference of opinion exists in regard to the activity of the circulation in muscle during contraction; Ludwig and his pupils maintaining that it is accelerated, whilst Bernard considered that it was nearly arrested.

628. The unstriated muscles of different animals react differently to heat.† The smooth muscular tissue of the bladder of the Frog elongates on being warmed, and shortens on being cooled, but the opposite occurs with the smooth muscular tissue of the rabbit and cat; nevertheless, if long kept at a high temperature the unstriated muscles of warm-blooded animals gradually relax, whilst the transversely striated muscles passing into rigor, remain shortened. The striated muscle of the frog, when excised and suddenly exposed to a temperature of 77° F., undergoes slow shortening; at 86° F., the shortening becomes more marked; and at 113° F., reaches its maximum. v. Bezold‡ and Prevost have found that in a certain stage of Veratrin poisoning the muscles respond to a single electric shock, not with a single short contraction, but with a persistent tetanic contraction; and, according to Weyland, the same results from the action of Sabadillin, Delphinin, Emetin, and Aconitin.§ As regards chemical agents, some appear to act with equal energy in producing contraction, whether applied to the muscle or to the motor nerve, as solutions of potash and soda; others, as creosote, alcohol, pure lactic acid, and glycerin, act on the muscle through the nerve, but possess little stimulating power when directly applied to the muscle; and others again excite energetic contraction when made to act immediately on the muscle, but scarcely operate through the nerve, as sulphate of copper and ammonia.‖ Kühne¶ remarks that all those bodies which coagulate the muscle plasma, as dilute acids and alkalies, act as powerful stimulants to muscles even when very dilute. The metallic salts, as a rule, require to be in a stronger state of concentration. He thinks that each part as it contracts, generates material (paralactic acid) which again acts as an excitor to the next adjoining layer.

629. Muscular Irritability is deadened by many substances, and especially by those which have a narcotic or sedative action on the nervous system. In carbonic acid gas, hydrogen, carbonic oxide, or sulphurous acid gas, muscles contract very feebly, or not at all, when stimulated; whilst in oxygen they

¶ "Physiol. Chemie," 1868, p. 311.

retain their irritability longer than usual. Narcotic substances, such as a watery solution of opium, when applied directly to the muscles, have an immediate and powerful effect in diminishing or even destroying their irritability; this effect is also produced, though in a less powerful degree, by injecting these substances into the blood. In the same manner venous blood charged with carbonic acid, and deficient in oxygen, has the effect of a poison upon the muscles, diminishing their irritability, when it continues to circulate through them, to such a degree that they sometimes lose it almost as soon as the circulation ceases, as is seen in those who have died from gradual and therefore prolonged asphyxia. The unfavourable influence of venous blood is also shown in the Morbus Cœruleus, patients affected with which are incapable of any considerable muscular exertion. Although most of the stimuli which occasion the contraction of muscles, when directly applied to their fibres, operate also when applied to their motor nerves, the same does not hold good in regard to those agents which diminish irritability. It is a fact of some importance in relation to the disputed question of the connection of muscular irritability with the nervous system, that when, by the application of narcotic substances to the nerves, their vital properties are destroyed, the irritability of the muscle may remain for some time longer, showing that the latter must be independent of the former.—The effects produced by the Curare and Upas Antiar poisons in this respect are exceedingly curious, and have been carefully studied by Bernard* and others. Curare, Conia, and, as Drs. Crum Brown and Fraser† have shown, the Sulphates and Iodides of Methyl-Strychnium, Methyl-Brucium, Methyl-Thebaium, Methyl-Codeium, and Methyl-Morphium all act directly upon the motor nerves, whilst Cyanide of Potassium and the poison of the Upas Antiar abolish the irritability of the muscular tissue itself. The evidence given by Bernard in proof of this last statement is very satisfactory, for he has shown that the cause of death after the administration of a sufficient dose of Curare is the cessation of the respiratory movements owing to paralysis of the motor nerves; for not only has it been proved by v. Bezold that by this agent the rapidity of the conduction of stimuli through the motor nerves is greatly reduced and ultimately abolished, but it is certain that perfect recovery may take place if artificial respiration be maintained for a sufficient length of time to enable the poison to be eliminated from the system or decomposed within it; whilst in fœtuses, and during the earlier stages of existence of fishes and other animals that are not directly dependent upon muscular movements for the aëration of their blood, this being accomplished by the umbilical vesicle, little or no injurious effect is experienced, the animals continuing to swim about in a watery solution of the poison without apparent inconvenience. That the sensory nerves are not affected, seems to be proved by the experiments of Kölliker and Funke, who observed that reflex actions could readily be excited in parts kept free from the circulation of poisoned blood by the ligature of their vessels, on pricking or pinching the skin of parts poisoned by the admission of blood containing Curare. The influence of the poison seems to be first felt by the peripheral extremities of the motor nerves, and its paralyzing effect gradually extends centripetally through the trunks.—An additional argument may be mentioned in favour of the essential independency of muscular irritability, in the circumstance that,

* See his Lecture in "Med. Times and Gazette," 1860, vol. ii.; also A. v. Bezold in "Monatsbericht der Berlin. Akad.," 1859; and Martin-Magron and Buisson in "Journal de la Physiologie," 1860.

† "Transact. of the Roy. Soc. of Edinb." 1868. A paper of great value on the connection between chemical constitution and physiological action.

although spontaneous movements occur in the muscles of embryos, the muscles cannot, in the earlier periods of fœtal life, be incited to contract by stimuli directly applied to their nerves.—Dr. Harless* again found that when the Nervous system had been rendered, by the inhalation of ether, utterly incapable of conveying a galvanic stimulus applied either to the nervous centres or to the nerve-trunks, the same stimulus applied directly to the muscles would immediately throw them into powerful contraction. Various other experimenters have shown that when the nerves supplying the muscles of a limb are divided and the animals are allowed to live, excitants applied to the nerves beyond the point of division fail to produce muscular contraction long before they cease to do so when applied to the muscles themselves. Hence it is obvious that the activity of the Nervous system is not essential to the manifestation of the characteristic endowment of the Muscular.

630. The contractions of the Heart present some differences from those of ordinary striated muscular tissue, probably depending upon the peculiar arrangement of its fibres, whereby the contraction of one set gives a mechanical stimulation to others; for the muscular substance of a large part of the organ is thrown into rapid and energetic contraction by a stimulus applied at any one point, and this contraction is speedily followed by relaxation, which is again succeeded by a number of alternating contractions and relaxations.† Each contraction, however, has been shown to be equivalent to a single shock in an ordinary striated muscle (§ 626). On the other hand, if we apply a similar irritation to a portion of non-striated fibre, as that of the Intestinal Canal, the fasciculus which is stimulated will contract less suddenly, but ultimately to a greater amount; its relaxation will be less speedy, and before it takes place, other fasciculi in the neighbourhood begin to contract; their contraction propagates itself to others, and so on. In this manner consecutive contractions and relaxations may be produced through a considerable part of the canal by a single prick with a scalpel. Again, in the muscular structure of the Bladder and Uterus (when the latter is fully developed), direct irritation excites immediate and powerful contractions, which extend beyond the fasciculus actually irritated, and produce a great degree of shortening; but they do not alternate in the healthy state with any rapid and decided elongation. Similar phenomena may be observed on irritation of the smaller arteries. In order to obtain the full contraction of a muscle by irritation applied to the nerves, it is requisite that the stimulus should be applied for a certain length of time; thus Budge‡ found that when an electric current was passed through the cervical region of the spinal cord of a rabbit for the space of half a second, the pupil dilated about one-sixth of an inch; but on continuing the application for three seconds, dilatation occurred to the extent of nearly one-third of an inch. In all cases relaxation speedily alternates with contraction, unless the operation of the stimulus be continued—as when an electric current is propagated without intermission along the nerve trunks—in which case the contraction lasts as long as the stimulus is continuously applied but ceases as soon as it is withdrawn. The singular "inhibitory" effects produced by irritation of some nerves, as the pneumogastric and splanchnic, have already (§§ 98, 226, 239) been alluded to; but further experiments are still required before it can be admitted that any nerve can really transmit a "stimulus to relaxation" on the part of the muscle to which it is distributed. The general fact that relaxation alternates with contraction at no long intervals

* Müller's "Archiv," 1847, Band ii.

† Ray Lankester (Pflüger's "Archiv," 1871, p. 315) has shown that the muscular tissue of the Heart is characterized by containing hæmoglobin. ‡ "Physiologie," 1862, p. 650.

is most evident in the rhythmical movements of the Heart,* and in the peristaltic action of the Intestinal Canal; since in these parts the whole or a large proportion of the fibres seem to contract together, and then shortly relax. But this is probably no less true of the individual fibres of those muscles which are kept in contraction by a stimulus transmitted through their nerves; since none of them appear, under ordinary circumstances at least, to remain in a contracted state for any length of time, a constant interchange of condition taking place among the fibres, some contracting while others are relaxing, and *vice versâ*. It is difficult to speak with confidence, however, in regard to the condition of the individual fibres of a muscle that is thrown into a state of *continued spasmodic* contraction. Whether the individual fibres in such instances maintain a state of contraction without intermission, or whether the contraction of the entire muscle is kept-up by a continual interchange of the fibres actually engaged, is a very curious subject for inquiry.

631. Muscles do not lose their Irritability immediately on the *general death* of the system, which must be considered as taking place when the circulation ceases without the power of renewal; in cold-blooded animals it is retained much longer after this period than in the higher Vertebrata, in some instances attaining its highest degree long after death has occurred,† whilst in the latter it frequently disappears within an hour. The muscles of young animals generally retain their irritability for a longer time than those of adults; on the other hand, those of Birds lose their irritability sooner than those of Mammalia. Hence, as a general rule, the duration of the irritability is inversely as the amount of respiration. From experiments on the bodies of executed criminals who were previously in good health, Nysten ascertained that in the Human subject the irritability of the several muscular structures disappears in the following time and order:—The left ventricle of the heart first, the intestinal canal at the end of 45 or 55 minutes, the urinary bladder nearly at the same time, the right ventricle after the lapse of an hour; the œsophagus at the expiration of an hour and a half, the iris a quarter of an hour later; the muscles of animal life somewhat later; and lastly, the auricles of the heart, especially the right, which in one instance contracted under the influence of galvanism 16½ hours after death. It will be presently shown that the departure of the irritability is essentially dependent upon the cessation of the circulation, and that it may be prevented from disappearing, and may even be recalled after it has ceased to manifest itself, by transmitting a current of arterial blood through the muscles. Kronecker‡ has endeavoured to establish

* Some curious rhythmical movements have been observed by M. Brown-Séquard ("Gaz. Med.," 1849) in the diaphragm, in the intercostals, and in some of the muscles of locomotion, both after death and after section of their nerves during life. These movements could not be in any way dependent upon reflex action, because they took place when the muscles were completely cut off from the nervous centres, sometimes to the number of from 5 to 20 in a minute, and for as long as a quarter of an hour after death; and occasionally recurred in living animals for many months afterwards, especially when the respiration was impeded and the circulation hurried. Of a similar nature are the vibratory movements of the muscles of the tongue witnessed by Schiff after section of the Hyoglossals ("Physiologie," 1859, p. 177); and we may perhaps refer to the same category the trembling movements of the hands and head in old age, in certain forms of paralysis, and in habitual drunkards and smokers. All these cases furnish evidence of a tendency to rhythmical movements in the muscles themselves, altogether independent of the excitement to action which they receive through the nervous system.

† See on the whole subject of the 'Irritability of Muscles,' a good paper by Dr. Norris in Humphry and Turner's "Journ. of Anat.," vol. i. p. 217. See also B. W. Richardson's 'Croonian Lecture on Muscular Irritability after Systemic Death,' Abst. in "Lond. Med. Record," June 18, 1873.

‡ See abstract of his paper in the "Journal of Anatomy and Physiology," vol. vi. 1872, p. 241.

certain laws of muscular exhaustion to this effect :—1. That if a muscle be overloaded with a definite weight, and irritated at equal intervals by equal induction shocks, the height of the contractions form an arithmetical series, in which the constant difference depends only on the interval of time. 2. The diminution in the height of the contractions is independent of the weight, and only depends on the interval between two contractions.*

632. We find, however, that sudden and severe injuries of the Nervous centres have power to *impair*, directly and instantaneously, or even to *destroy* the contractility of the whole Muscular system; so that death immediately results, and no irritability subsequently remains. It is in this manner that the *sudden* destruction of the brain and spinal cord, especially of the latter, occasions the immediate cessation of the heart's action, though they may be *gradually* removed without any considerable effect upon it. Severe concussion has the same effect; hence the syncope which *immediately* displays itself. It is sometimes an important question in forensic medicine, whether an individual who has died from the effects of a blow upon the head, could have moved from the place where the blow was inflicted. If there be found, as is frequently the case, no sensible disorganization of the brain, the death must be attributed to the concussion, and must have been in that case *immediate*. If, on the other hand, effusion of blood has taken place within the cranium to any considerable extent, it is probable that the first effects of the blow were in some degree recovered from, and that the circulation was re-established. It is not essential, however, that the impression should be primarily made upon the Cerebro-Spinal system. The well-known fact of sudden death not unfrequently resulting from a blow on the stomach, especially after a full meal, without any perceptible lesion of the viscera, clearly indicates that an impression upon the widely-spread cœliac plexus of Sympathetic nerves (which will be much more extensively communicated to them when the stomach is full than when it is empty) may cause the immediate cessation of the heart's action in the same manner as a violent injury of the brain or spinal cord.† In all these cases *the whole vitality* of the system appears to be destroyed at once; for the processes which would otherwise succeed to the injury, and which after other kinds of death less sudden in their character, produce evident changes in the part of the surface that has immediately received it, are here entirely prevented. An instance is on record in which a criminal under sentence of death determined to anticipate the law by self-destruction. Having no other means of accomplishing his purpose, he stooped his head and ran violently against the wall of his cell; he immediately fell dead, and *no mark* of contusion showed itself on his forehead. The same absence of the usual results is to be noticed in the case of blows on the stomach. The influence of severe impressions on the nervous system in *diminishing*, when it does not altogether destroy, muscular irritability, is well seen in the operation of severe injuries affecting vital organs, or extending over a large part of the surface, in depressing the heart's action; to which attention has already been directed (§ 222).

633. From a general consideration of the phenomena of Irritability, we can scarcely do otherwise than acquiesce fully in the doctrine of Haller, which involves no hypothesis, and which is perfectly conformable to the analogy of other departments of Physiology. He regarded every part of the body which is endowed with irritability as possessing that property in and by itself; but considered that the property is subjected to excitement and control from the

* See, in regard to the irritability of muscles after systemic death, B. W. Richardson, "Proceed. Roy. Soc." 339, 1874.

† For examples of this see "Lancet," 1870, vol. i. p. 276.

nervous system, the agency of which is one of the stimuli that can call it into operation. It may be desirable briefly to sum up the facts by which this doctrine is supported. 1. The existence in vegetables of irritable tissues, which are excited to contraction by stimuli directly applied to themselves, and which can be in no way dependent upon or influenced by a nervous system. 2. The existence in animals of a form of muscular tissue which is especially connected with the maintenance of the organic functions, and which is much more readily excited to action by direct stimulation than it is by nervous agency. 3. The fact that by the agency of these the organic functions may go on (so long as their requisite conditions are supplied) after the removal of the nervous centres (of the Cerebro-Spinal system at least), and when these were never present; rendering it almost certain that their ordinary operations are not dependent upon any stimuli received through the nerves, but upon those directly applied to themselves. 4. The persistence of irritability in muscles, for some time after the nerves have ceased to be able to convey to them the effects of stimuli: this is constantly seen in regard to the Sympathetic system of nerves, and the muscles of organic life upon which they operate; and it is shown, by the agency of narcotics, to be true also with respect to the Cerebro-Spinal system and the muscles of Animal life. 5. The continuance of irritability in the muscles after their complete isolation from the nervous centres, so long as their nutrition is unimpaired; and the effects of frequent exercise in preventing the impairment of the nutrition and the loss of irritability. 6. The recovery of the irritability of muscle, when isolated from the nervous centres, after it has been exhausted by repeated stimulation: this also depends upon the healthy performance of the nutritive actions. 7. The existence of certain poisons which appear to possess a directly depressing effect on the conducting power of motor nerves, without exerting any influence upon the irritability of muscles (§ 629). 8. The existence of certain tracts of muscular tissue, as those, for instance, of the walls of the umbilical vessels, which according to Virchow, whilst possessing considerable irritability, show no trace of nervous tissue. In the words of Dr. Alison, then, "the only ascertained final cause of all endowments bestowed on nerves in relation to muscles in the living body, appears to be not to make muscles irritable, but to subject their irritability in different ways to the dominion of the acts and feelings of the mind"—to its volitions, emotions, and instinctive determinations.*

634. The experiments of Mr. Gaskell† show that the flow of blood through muscles undergoes considerable variation under different circumstances. In muscles at perfect rest, with untouched nerves, the flow of blood from the veins is nearly absolutely regular. After section of the nerve supplying a muscle, the flow of blood through its vessels is immediately and greatly increased, probably owing to the division of the vaso-motor nerves and loss of tone in the vessels, but this effect is only temporary, and the flow falls to its normal amount. In some instances there is a secondary and more permanent rise on stimulation of the nerve, so as to produce tetanus. There is at first a spurt-like quickening of the stream, followed by an almost complete cessation of the flow, which then again steadily increases in volume. At the end of the tetanus the flow sinks for a moment, then rises to a new maximum, and finally falls to its original value. There can be no question that the condition most essential to the maintenance of muscular contractility is an *adequate supply*

* For a good *résumé* of the arguments for and against the theory of independent irritability in muscles, see a paper by Dr. H. N. Maclaurin in "Edinb. Med. Journal," July, 1863.

† "Journ. of Anat. and Phys.," vol. xi. 1877, p. 360.

of arterial blood. It is well known that when a ligature is applied to a large arterial trunk in the Human subject, there is not only a deficiency of sensibility in the surface, but also a partial or complete suspension of muscular power, until the collateral circulation is established. The same result has been constantly attained in experiments upon the lower animals; the contractility of the muscle being impaired or altogether extinguished when the flow of blood into it was arrested, and being recovered again when the supply of blood was restored.—The various experiments of Brown-Séquard* on this subject show that the contractility of muscles, whether of the striated or smooth variety, may not only be restored by the transmission of aërated blood through them, after it has entirely ceased, but that this may even occur when it has given place to cadaveric rigidity. Thus he found that when he connected the aorta and vena cava of the body of a rabbit which had been some time dead, and in which the cadaveric rigidity had already manifested itself for between ten and twenty minutes with the corresponding vessels of a living rabbit, so as to re-establish the circulation in the lower extremities, the rigidity disappeared in from six to ten minutes, and in two or three minutes afterwards the muscles contracted on being stimulated. He subsequently made similar experiments upon the muscles of a decapitated criminal; the hand being selected as a convenient part for the purpose. It was not until nearly $12\frac{1}{2}$ hours after death that all traces of irritability had left the muscles, and the injection was not commenced until 45 minutes after this, cadaveric rigidity having appeared in the interval. About half a pound of human blood, which had been defibrinated and freely exposed to the air so as to acquire the arterial tint, was then injected at intervals for about thirty-five minutes; ten minutes after the last injection, the greater number of the muscles were found to be irritable, and these remained so for two hours, after which the contractility gradually departed, and was succeeded by cadaveric rigidity. The blood which had been injected in an arterialized condition issued from the vessels quite dark; and as this occurred over and over again, the change of hue could not be attributed to anything else than the reaction between the blood and the tissues.—Similar experiments were made twenty-seven hours after death upon the muscles of the foot of the same criminal; but with an entirely negative result, save that the blood which was injected returned of a considerably darker hue.†—Still more recent experiments have shown that in order that the muscles should retain their elongated condition, it is necessary that they should be supplied with arterial blood, the passage of venous blood through their capillaries immediately inducing contraction. This was remarkably exemplified in an experiment made by M. Brown-Séquard upon a pregnant rabbit, in which the injection of venous blood into the uterine vessels immediately excited the organs to contract, and caused the expulsion of two or three fœtuses, whilst on injecting arterial blood all signs of contraction immediately passed off. It is doubtful whether

* See "Gazette Médicale," 1851, Nos. 24 and 27; and "Journal de la Physiologie," 1858, vol. i. pp. 95, 353, 729. For some more recent experiments, see M. Robin in his "Journal de l'Anatomie," 1869, p. 69.

† In Robin's experiments upon decapitated criminals, the heart could be made to recommence its rhythmical contraction by blowing air into its cavities upwards of one hour and a quarter after execution. The contractions continued for eight minutes. Rosenthal ("Wien. Med. Press," 1872, Nos. 18 and 19) found that the muscles of the trunk and extremities of man lose their irritability and cease to respond to farado-electrical excitation within a period varying from 90 to 180 minutes after death. In frogs the irritability of the muscles lasts for many hours when kept in a moist chamber. Newman, "Journal of Anat. and Phys.," vol. xiii. 1879, p. 573, found the fibres respond to the stimulus of an acid or alkaline solution 70 hours after the death of the animal.

the stimulus to contraction in these cases is the presence of carbonic acid, or whether, as Dr. Radcliffe* supposes, it is not rather to be attributed to a deficiency of oxygen, the readmission of which restores the vital properties of the muscle and induces its elongation. The latter view is certainly supported by the violent convulsions which occur in animals that are bled to death; and even the convulsions which are witnessed in asphyxia, when the contracted state of the small arteries (§ 300) and the consequent diminished transmission of blood through the capillaries are borne in mind, are not unfavourable to it. Dr. Radcliffe has adduced the interesting experiments of Dr. George Harley† upon the influence of the addition of strychnia and brucia to blood, as essentially confirmatory of his view; since these poisons diminish the capacity of the blood to absorb oxygen, and their action may thus be said to be equivalent to a copious loss of blood.

635. Whilst the Irritability of Muscles is gradually departing after death, it not unfrequently shows itself under a peculiar form; for, instead of producing sudden contractions, speedily followed by relaxation, the application of Stimuli then occasions slow and somewhat prolonged contractions, the relaxation after which is tardy. This form of contraction is seldom seen in adult Mammalia, except (as will be presently shown) when death has taken place from certain diseases that have a special influence on the blood and muscular system; but it is stated by M. Brown-Séquard‡ to present itself more constantly in young animals, and to be (so to speak) an exaggeration of the ordinary *modus operandi* of their muscles, which during life are much more slowly thrown into contraction by mechanical stimuli than they are in adults. —The most remarkable manifestations of it yet observed, however, have been witnessed after death from Cholera and Yellow Fever; for in these cases the muscular contractions, though capable of being excited by mechanical stimulation applied to the muscles themselves, are frequently spontaneous, and sometimes give rise to movements strongly resembling the ordinary actions of the living state. In regard to the occurrence of this phenomenon, after death from yellow fever, several interesting observations have been recorded by Dr. Bennet Dowler, of New Orleans.§ In one case, the subject of which was an Irishman, aged twenty-eight, the following series of movements took place spontaneously not long after the cessation of the respiration; first the left hand was carried by a regular motion to the throat, and then to the crown of the head; the right arm followed the same route on the right side; the left arm was then carried back to the throat, and thence to the breast, reversing all its original motions, and finally the right hand and arm did exactly the same. Similar phenomena have been described by Mr. N. B. Ward, Mr. Helps, and Mr. Barlow‖ as occurring in the bodies of cholera patients. Many circumstances indicate that these movements were due to the inherent contractility of the muscles, and were not in any degree dependent upon the operation of the nervous system; and Mr. Dowler proved experimentally, by completely separating limbs which exhibited these movements from the trunk of the body, that the influence of the nervous centers was not in any degree essential to their production.

636. The *Rigor mortis*, or Cadaveric rigidity of the muscles, is essentially

* In whose work "On Epileptic and other Convulsive Affections of the Nervous System" (3rd edit., 1861) much original and interesting information on the subject of muscular contractility will be found.

§ "Experimental Researches on the Post-mortem Contractility of the Muscles," 1846.

‖ See Mr. F. Barlow's 'Observations on the Muscular Contractions which occasionally occur after Death from Cholera,' in "Med. Gazette" for 1849–50.

the result of the coagulation of myosin (which, according to Michelson, is due to the action of a ferment),* and is attended with the liberation of heat. It begins immediately after all indications of irritability have departed, but before any putrefactive change has commenced. The supervention of the rigidity is not usually prolonged much beyond seven hours, though a tetanic state at first sight resembling it may occasionally be observed to occur instantly after death from some peculiar conditions of the nervous and muscular systems at the moment. In other instances twenty or even thirty hours may elapse before it shows itself. Its general duration is from twenty-four to thirty-six hours, but it may pass off much more rapidly, or it may be prolonged to four or six days. It first affects the neck and lower jaw, then the trunk, then the upper extremity, and finally the muscles of the lower extremities. In its departure, which is immediately followed by decomposition, the same order is followed. It is remarkable that it is equally intense in muscles which have been paralyzed by Hemiplegia, or whose nerves have been previously severed, provided that no considerable change has taken place in their nutrition. It was the opinion of Mr. Hunter that death from exhaustion by hunting, as well as by lightning, completely prevents the post-mortem rigidity of muscles, and the coagulation of the blood. But the observations of Gulliver† have proved that in animals killed by hunting and by fighting, the rigor mortis is greatly hastened, and that the blood does coagulate. He found that deer, foxes, and hares became quickly stiff after being hunted to death; and that game fowls, exhausted and worried to death by fighting, become quite stiff, and have the blood coagulated in their hearts within twenty-eight minutes after the last fatal wound. Rigor mortis, induced by exposure to heat or 'Heat rigor,' occurs in cold-blooded animals at 104°–109° F., in mammals at 118°–122° F., and in birds at 128° F. The immersion of Batrachian reptiles in water at a temperature of about 120° kills them instantly, all their muscles becoming immediately very stiff. The application of acids, even when very feeble or dilute, speedily causes 'acid rigor.' It may be said that all circumstances which tend to exhaust or depress the irritability of the muscles, such as death by slow and wasting disease, violent muscular exertion immediately before death, or powerful electrical shocks passed through the motor nerves, induce the early appearance and speedy departure of this state—putrefaction subsequently appearing and progressing rapidly. On the other hand, when the general energy has been retained up to a short period before death, as in persons who die from an accidental cause, or in animals the irritability of whose muscles has been augmented by cold, cadaveric rigidity sets in late and lasts long, and putrefaction also appears late and progresses slowly. Muscles deprived of blood by the ligature of their arteries, or brought into contact with distilled water, ammonia, dilute acids, alkaline salts, metallic salts, alcohol, or chloroform (all of which produce coagulation of the myosin, whilst some of them act on the other albuminous constituents of muscle), pass into a state closely analogous to, if not identical with Rigor mortis; and within certain limits their powers can be restored by the readmission of a current of duly oxygenated or arterial blood. The contractile force exerted in Rigor mortis, according to Hermann and Walker‡ is generally less than, though sometimes fully equal to, or even greater than that which the muscle can exert on strong electrical excitation.—The condition of the muscles in post-mortem rigidity is in many respects different from that of the contraction

* "Journ. of Anat. and Phys." 1874, p. 213.
† "Edinb. Med. and Surg. Journ.," Oct. 1848.
‡ Pflüger's "Archiv," Band iv. 1871, p. 182.

which occurs during life. In the former the shortening is persistent and uniform, the elasticity of the tissue is increased;* and when it is induced by Heat, a distinct diminution in the bulk of the muscle occurs; it feels firm and hard, and there are no signs of electrical disturbance; it cannot be excited to contract by the application of any stimulus. In the latter, on the contrary, the contraction is intermittent, and there is, as we have seen, a diminution in the amount of the elasticity and of firmness, and evidence of a change in the state of electrical tension (negative variation).—In Rigor mortis the muscles generally have an acid reaction, owing to the presence of sarco-lactic and glycerin-phosphoric acids; but this is not always the case, and the two conditions are therefore independent of each other.† According to Ranke‡ and Hermann, living muscle absorbs far more oxygen than dead; as is shown in the following table:—

Temperature.	*Excess of oxygen absorbed by living over dead muscle.*
0°—2° C.	24·73 vol. per cent.
7°—9° C.	14·72 „ „
15°—20° (Hermann's Experiment)	3·61 „ „
45°—55° C.	2·01 „ „

The absorption here indicated is clearly of a physiological nature, since it steadily diminishes with increasing elevation of temperature, which hastens the death of the muscle, and would prove favourable to any purely chemical changes.

637. It was formerly customary to divide the Muscles into two groups, termed the "voluntary" and "involuntary," coresponding to the "striated" and "non-striated" tissue respectively, but there are various circumstances which show that this system of classification cannot be consistently maintained. It is quite true that all the Muscles of Organic Life may be truly styled 'involuntary;' for although they are capable of being influenced by emotional and ideational states of mind, yet the Will cannot exert any direct influence upon them, only affecting them indirectly by its power of determining these states. But over those Muscles, also ministering to the organic functions, and doing so in obedience to impulses purely automatic, which are called into action by the Cranio-Spinal nerves, the Will, as we have seen, exerts some power; and such, therefore, cannot be properly regarded as involuntary, since the Will can influence their state; whilst they are far from being truly voluntary, since the Will cannot control their tendency to automatic action beyond a certain limited amount (§ 271). On the other hand, every one of the muscles usually styled voluntary, because ordinarily called into action by the Will, is liable to be thrown into action involuntarily; either by an Excito-motor stimulus, as in tetanic convulsions, or by Consensual action, as in tickling, or Emotionally, as in laughter or rage, or simply Ideationally, as in somnambulism and analogous states. Hence although there are certain groups of muscles which are more frequently acted on by the Will than by any other impulse, and certain others which are more frequently played on by the Emotions, and so on, it becomes obvious that every muscle called into contraction by the Cranio-Spinal nervous system is capable of receiving its stimulus to movement from *any* of these sources; the nerve-force transmitted along the motor-fibres being issued either from the Spinal Cord, from the Sensory Ganglia, or from the Cerebrum, as the case may be, but being in its nature and effects the same in every instance.

* There seems to be some difference of opinion on this point, Hermann and Walker (Pflüger's "Archiv," 1871, Band iv. p. 182) maintaining that muscles in Rigor mortis possess a greater extensibility than contracted muscles. † Wundt, "Physiologie des Menschen.," 1873, p. 476.

‡ "Die Lebensbedingungen der Nerven," 1868, p. 33.

638. The grouping or combination of muscular actions, which takes place in almost every movement of one part of the body upon another, must be attributed, not to any peculiar sympathy among the Muscles themselves, but to the mode in which they are acted on by the Nervous Centres. This is most obviously the case with regard to those of the primarily-automatic class; but it can scarcely be doubtful as to those of the secondarily-automatic kind (§ 501), such as walking, which, though at first directed by the Will, come by habit to be performed under conditions essentially the same with the preceding; and when it is borne in mind that even in voluntary movements the Will cannot single out any one muscle from the group with which it usually co-operates, so as to throw this into separate contraction, but is limited to determining the result, it seems pretty obvious that even here the grouping is effected by the endowments of those Automatic centres from which all the motor impulses immediately proceed to the muscles, and not by Cerebral agency. In fact, the whole process by which we acquire the power of adapting our muscular actions to the performance of some new kind of movement—as in the case of an infant learning to walk, a child learning to write, an artizan learning some occupation which requires nice manipulation, a musical performer learning a new instrument, and so on—is found, when attentively studied, to indicate that the Will is far from having that direct and immediate control over the contractions of the Muscles, which it is commonly reputed to possess; and that the operation really consists in the gradual establishment of a new grouping of the separate actions, in virtue of which the stimulus of a Volitional determination, acting under the guidance of the muscular sensations (§ 641), henceforth calls into contraction the group of muscles whose agency is competent to carry that determination into effect. For however amenable any set of muscles (as those of the arm and hand) may have become to the direction of the Will, in any operations which they have been previously accustomed to perform, it is only after considerable practice that they can be trained to any method of combined action which is entirely new to them; and even if we attempt to bring our anatomical knowledge into use for such a purpose, by mentally fixing upon certain muscles whose action we wish to intensify and to associate with those of others, we find that such a method of proceeding affords no assistance whatever, but rather tends to impede our progress, by drawing off the attention from the 'guiding sensations' (visual, muscular, &c.), which are the only regulators that can be depended upon for determining the due performance of the volitional mandate. —Hence we are led by these considerations, as by those stated in the preceding paragraph, to the conclusion, that the agency which directly affects the muscles is of the same kind, and that it operates under the same instrumental conditions, whatever be the primary source of the motor power. And in watching the gradual acquirement of the capacity for different kinds of movement, during the periods of Infancy and Childhood in the Human subject, we find everything to confirm this conclusion. For it becomes obvious that the acquirement of voluntary power over the movements of the *limbs* is just as gradual as it is over the direction of the *thoughts;* all the activity of the *body*, as well as of the *mind*, being in the first instance automatic; and the Will progressively extending its domination over the former, as over the latter, until it brings under its control all those muscular movements which are not immediately required for the conservation of the body, and our will turns them to its own uses.*

* The aptitude which is acquired by practice, for the performance of certain actions that were at first accomplished with difficulty, seems to result as much from a structural change

2. *Of the Symmetry and Harmony of Muscular Movements.*

639. It might have been not unreasonably supposed, *d priori*, that those muscles would have been most readily put to simultaneous contraction which correspond to each other on the two sides of the body; in other words, that *symmetrical* movements would be those most readily performed. Such, however, is by no means the case; for in many of our most familiar actions we consentaneously exert different muscles on the two sides of the body. This is nowhere more clearly shown than in the various movements that are required for the performance of the different acts of locomotion, and which may here be briefly noticed. In order to maintain the body in the erect posture, simple as the effort appears, the concurrent action of many muscles is required, as is clearly shown not only by the numerous and futile trials made by children before the power of balancing is acquired, but by the impossibility of placing a dead body in this position without support. In *standing*, the legs are more or less extended; and the weight of the trunk is transmitted through the femora and the tibiæ and fibulæ to the astragali. These, with the other tarsal and metatarsal bones, form an elastic arch on either side, which, whilst allowing the great superincumbent pressure to be borne with ease, enables each foot to accommodate itself to irregularities of the surface of the ground, and at the same time breaks the shock or jar which would otherwise be experienced in the various movements of walking, running, or leaping. The centre of gravity of the whole body lies, according to Weber, in the promontory of the sacrum; but, according to Meyer, in the canal of the second sacral vertebra. As long as a perpendicular line drawn from this point to the earth drops within the basis formed by the feet, the erect posture can be maintained with comparative ease; if it drop outside that basis, the subject must inevitably fall. The chief muscles called into play in the standing position are those which keep the head vertical on the spinal column, as the recti, obliqui, sternomastoids, splenii, complexus, &c., the extensors of the spine, as the erectores spinæ and their prolongations, and the extensors of the thigh and leg; but the opposite muscles are, as a sailor would express it, 'taut,' and ready to contract instantaneously and unconsciously on the slightest indication of loss of equilibrium.

640. *Walking.*—In this movement the body, supported in a nearly vertical position, alternately rests on the right and left leg; the limb upon which it does not rest swinging forward, like a pendulum, in a remarkably regular manner, just sufficiently bent to avoid contact with the ground. This is not effected, however, quite apart from muscular action, since, as M. Duchenne has shown, certain muscular paralyses (of flexor muscles) prevent the oscillation from occurring.* If we examine the successive movements which occur in making two steps, it will be found that if the subject be standing firmly with the left leg in advance, the first act consists in raising the heel of the

which the continual repetition of them occasions in the Muscle, as in the habit which the Nervous system acquires of exciting the movement. Thus almost every person learning to play on a musical instrument, finds a difficulty in causing the two shorter fingers to move independently of each other and of the rest; this is particularly the case in regard to the ring-finger. Any one may satisfy himself of the difficulty, by laying the palm of the hand flat on a table, and raising one finger after the other, when it will be found that the ring-finger can scarcely be lifted without disturbing the rest,—evidently from the difficulty of detaching the action of the portion of the *extensor communis digitorum*, by which the movement is produced, from that of the remainder of the muscle. Yet to the practised musician, the command of the Will over all the fingers becomes nearly alike; and it can scarcely be doubted that some change in the structure of the muscle, or a new development of its nerve-fibres takes place, which favours the isolated operation of its several divisions.

* Duchenne (de Boulogne), "Physiologie des Mouvements," Paris, 1867, p. 386.

right foot, which is accomplished by the gastrocnemius and soleus muscles; and the weight of the whole body thus raised is by the simultaneous contraction of the psoas and iliacus muscles of the left leg thrown over to the left side, resting for an instant upon the left foot. At this period all the extensors of the left leg, the glutæi, the quadriceps extensor femoris, the tibialis anticus, &c., are powerfully contracted. The right leg, the toe of which is the last part which touches the ground, now swings forward, the knee and hip joints being just sufficiently bent to enable the foot to clear accidental irregularities of the surface. Lastly, the right heel is planted on the ground in front, and is immediately followed by the whole surface of the foot; but coincidently with this occur the elevation of the left heel and the throwing over of the weight of the trunk to the right side, which is followed by the swinging forward and implantation of the left foot, and so on alternately. The weight of the legs in the act of swinging forward has been shown by Weber to be materially diminished by the pressure exerted by the atmosphere in retaining the head of the femur in the acetabulum. The ordinary rate of movement in walking for each person is to an important extent regulated by the length of the leg, and the consequent duration of its pendulum-like oscillation. Various compensatory movements in walking occur in order to maintain the equipoise of the body; amongst the most important of these are the movements of the arms, for whilst the right leg is swinging forward, the twisting of the trunk which occurs at this period would bring the right shoulder forwards, but the right arm at this moment sways backwards and the left forwards, and by thus generating a force in the opposite direction neutralizes this tendency. A corresponding compensation takes place when the left leg swings forward, and this is effected by a good walker without any sensible lateral twisting of the trunk.* The whole body rises and falls to a small amount ($1\frac{1}{4}$ inch) in walking, &c. The trajectory of any fixed point of the body, as the pubis, may, according to the formula of M. Carlet, be inscribed in a hollow half cylinder with its concave portion upwards, at the base of which lie the minima, and on the sides of which the maxima terminate tangentially. M. Carlet,† who has lately bestowed much attention on the movements of locomotion in man, divides each step into two parts—one, during which both feet are in contact with the ground (*temps du double appui*), and the other when the body is supported by one foot alone (*temps de l'appui unilatéral*). A. *Period of Double Contact.*—1. At the beginning of the period of double contact, when the foot in front only touches the ground with the heel, the posterior leg is stretched, and rests only on the extremities of the metatarsal bones and the phalanges. The knee of the front leg is extended or slightly flexed. The bicotyloidean axis is oblique, from before backwards, and from above downwards. The trunk descends at the same time that its lateral and forward inclination diminishes. The pubis is turned towards the side of the posterior leg. 2. In the middle of the period of double contact, that is to say when the front foot begins to touch the ground along its whole length, the posterior leg only touches it with its phalanges. The knee of the fore leg is rather more bent. The position of the bicotyloidean axis is the same as before. The trunk has gained its lowest position. The pubis is situated above the axis of the path to be pursued. 3. At the end of the period of double contact, that is when the posterior leg only touches the ground by

* See Bishop in "Cyclop. of Anat. and Phys.," vol. iii. p. 460.

† Carlet, 'Essais expérimentals sur la Locomotion,' in the "Annales des Sci. Nat.," 1872. The reader may also refer to Marey's 'Animal Mechanism,' vol. xi. of the "International Scientific Series," and to Pettigrew's 'Animal Locomotion,' vol. vii. of the same series.

the ends of its phalanges, the front leg has begun to extend the knee-joint. The bicotyloidean line is oblique as before. The trunk begins to be raised at the same time that it inclines forwards and to the side. The pubis is directed obliquely towards the side of the front leg. B. *Period of Single or Unilateral Contact.*—1. At the beginning of this period, that is when the posterior foot is about to quit the ground, and the front foot is planted flat, the supporting leg continues to open or extend the knee-joint, whilst the opposite one begins to be flexed. The bicotyloidean axis is oblique, but from before backwards only, being otherwise horizontal; the trunk begins to rise at the same time that it inclines forwards and to the side. The pubis is directed obliquely outwards, towards the side of the leg in front. 2. In the middle of the period of unilateral support, that is when the heel of the supporting leg quits the ground, it extends the articulation of the knee to the utmost. In the leg that is suspended in the air, on the contrary, the knee is flexed to its maximum amount. The bicotyloidean axis is always oblique, but from above downwards only. It lies in a vertical plane, and its lower extremity corresponds to the supporting limb; the trunk has reached its greatest elevation, and at the same time its inclination forwards and to the side is at its maximum. The pubis is at its maximum of obliquity as regards the path pursued on the side of the supporting leg. 3. At the close of the period of unilateral support—that is, when the supporting leg touches the ground only by its metatarso-phalangeal portion, and the free leg has passed the middle of its period of oscillation, the ankle-joint of the supporting leg extends or opens whilst that of the knee remains at its maximum of extension. The bicotyloidean axis becomes again oblique from before backwards, and from above downwards; but its obliquity is now in the opposite direction, and the limb which was in front and above in the period of double contact is now behind and below. The trunk descends at the same time that its forward and lateral inclination diminishes. The pubis approximates the axis of the path. If the length of the steps increases, their duration in *general* diminishes, whilst the falling of the trunk and its inclination always augment. The number of steps in a given time, or the pace of walking, is partly dependent upon the length of the legs, and partly upon direct muscular effort: the longer the leg, the slower will be the oscillation; but by planting the foot on the ground when it has only passed through one-half of its natural oscillation, the succession of steps, and consequently the rapidity of progress, can be materially increased without much effort. In very quick walking almost every muscle in the body is brought into play; the trunk is considerably inclined forwards, partly for the purpose of resisting and compensating for atmospheric pressure, but chiefly to enable the hip-joints to be carried low, thus increasing the extent of ground which can be covered by each step, whilst at the same time the number of steps is greatly increased by muscular effort; the period during which both feet are resting on the ground together being considerably shortened. In an experiment made by Mr. Vasey, the length of whose leg was thirty-four inches, in walking at the rate of four miles an hour, 2,000 steps were made every fifteen minutes; the length of each step must therefore have been 2·64 feet, and the time of each step 0·45 second. M. Carlet has shown that the muscular effort in walking, as indicated by the backward push, supposing the weight of the individual to be about 150 pounds, does not surpass 45 pounds additional, though it is much greater in leaping and running.—Quick walking passes by insensible gradations into *running*, the period in which the body rests upon both feet becoming shorter and shorter, until at length there is a period between successive steps during which the body moves forward unsupported

by either foot. According to Weber, the vertical undulations of the trunk in running vary from 3–4ths to 4–5ths of an inch, the duration of the step from 1–4th to 1–5th of a second, of which time the body swings unsupported in the air 1–10th of a second, the time of descent being 1–15th of a second.—In *leaping*, the extensor muscles are brought into extremely vigorous action, and the act may be accomplished either by the alternative or the simultaneous action of the legs, as seen in the "hop, step, and jump" of children. The essential difference in leaping and running is, that in leaping the body is raised so high from the ground and for so long a period that the leg or legs have time to complete their full arc of oscillation, and consequently cover the utmost space of ground possible. The extent of the leap is of course dependent upon the muscular energy of the individual.*

641. Now it is plain that the grouping of the muscular movements in these different instances arises out of its *felt* conformity to the end in view, and that it is regulated by the guiding sensations which indicate to us the progression and balance of the body. The infant, in learning to walk, is prompted by an instinctive tendency to put one foot before the other, as may be noticed at a very early period, when it is first held so as to feel the ground with its feet; and in attempting to balance itself when first left to stand alone, it moves its arms with a like intuitive impulse, not based upon experience. All that experience does, in either case, is to give that precise adjustment to the muscular action which makes it perfectly conformable to the indications afforded by the muscular sensations. Thus, if we advance each arm with its corresponding leg, we feel that the balance of the body is not nearly as readily maintained as it is when we advance the arm with the leg of the opposite side; and thus, without any design or voluntary determination on our parts, the former comes to be our settled habit of action. This kind of adjustment, as in the case before us, is by no means limited to the muscles of the limbs; for there is scarcely any muscle of the trunk or head that is not exerted with some degree of consentaneous energy, however unconsciously to ourselves, in the act of walking. The difficulty which would attend the voluntary harmonization of all these separate actions is remarkably evinced by the fact, that no mechanist, however ingenious, has ever succeeded in constructing an automaton that should *walk* like Man; the alternate shifting of the centre of gravity from one side to the other, upon so small a base as the human foot affords, simultaneously with the movement in advance, constituting the great difficulty of biped progression. But all this adjustment is effected in our own organism *for* us, rather than *by* us; the act of harmonization, when once fully mastered, being attended with no effort to ourselves; but the whole series of complex movements being performed in obedience to the simple determination *to walk*, under the automatic guidance of the senses, which instantly reveal to us any imperfection in the performance.—The same view extends itself readily to other combinations of dissimilar and non-symmetrical movements, which are less *natural* to Man, but which may be readily acquired *artificially* if they all harmonize in a common purpose and are under the guidance of the same set of sensations. Thus, the performer on the Organ uses the several fingers of his two hands to execute as many different movements (in very different positions, it may be) on the 'manual' keys: one of his feet may be on the 'swell' pedal, and the other

* The subject of the locomotion of Man has been particularly investigated by the Profrs. Weber, whose work entitled "Mechanik der menschlich. Gehwerkzeuge" (Göttingen, 1836) has been translated in Jourdan's "Encyclopédie Anatomique," tom. ii. See also the Art. 'Motion' by Mr. J. Bishop, in "Cyclop. of Anat. and Physiol.," vol. iii.

may be engaged in playing on the 'pedal' keys; but all these diverse actions are harmonized by their relation to the same set of auditory sensations; and if the result be not that which the performer anticipated, an immediate correction is made. The preferential use of the right arm and leg is not easily explicable. Dr. Pye-Smith* refers it to the principle of the "survival of the fittest," contending that in warfare those who advanced the right side would in the long run be exposed to less risk of fatal wounds. Dr. Ogle,† however, points out that the right extremities are used preferentially by other animals, as the monkey and parrot, and refers it to the fact that the left hemisphere receives a freer supply of blood than the right. It may to some extent proceed from imitation, and to some extent also be the result of education.

642. It would be easy to multiply instances of the same kind, all illustrative of the general principle, that the facility with which we voluntarily combine different movements is chiefly determined, not by their *symmetrical* character, but by their *conformableness to a common end*, and by the *harmony of their guiding sensations* with reference to that end;‡ but it will be desirable to dwell particularly on the *Movements of the Eye*, as presenting certain points of peculiar interest, some of which have an important bearing on Surgical practice.—It will be recollected that in the Human Orbit, six muscles for the movements of the eyeball are found; the four Recti, and the two Oblique muscles. The precise actions of these are not easily established by experiment on the lower animals; for in all those which ordinarily maintain the horizontal position, there is an additional muscle, termed the *retractor*, which embraces the whole posterior portion of the globe, and passes backwards to be attached to the bottom of the orbit.§ If the origin and insertion of the four *Recti* muscles be examined, however, no doubt can remain that each of them, acting singly, is capable of causing the globe to revolve in its own direction—the superior rectus causing it to roll towards the nose—and so on. A very easy and direct application of the laws of mechanics will further make it evident to us, that the combined action of any two of the Recti muscles must cause the pupil to turn in a direction intermediate between the lines of their single action; and that *any* intermediate position may thus be given to the eyeball by these muscles alone. In two directions, however, their combined action is supplemented by the oblique muscles. The superior oblique rotates the eye downwards and outwards; the inferior oblique upwards and outwards. Another important operation of the oblique muscles is to maintain the

† 'Rep. of Med.-Chir. Soc.,' "Lancet," 1871, p. 449. See also, for scattered Notes and Observations on this subject, "Lancet," 1860, vol. i. pp. 526, 557, 660; 1871, vol. i. p. 495; vol. ii. pp. 49 and 111; Buchanan, 'Theory of the Right Hand,' "Edinburgh Med. Journ.," 1863; and Pamphlet, Glasgow, 1862. Poncet, "Gaz. Hebdom.," 1875, No. 36, finds that in right-handed persons the right, in left-handed persons the left, bones exceed those of the opposite side in weight by about 17 grammes = 262·48 grains, or nearly half an ounce.

‡ Two simple examples, however, may be cited, of the difficulty which attends the simultaneous performance of movements that are not harmonious. If we attempt to elevate one eyelid whilst we are depressing the other, we find that a considerable effort is required to accomplish the action, although the elevation or depressing of both eyelids together is performed with so little effort that we are scarcely conscious of it; and the difficulty is increased if we half shut both eyes, and then try to close one and to open the other. So if we try to move our two hands as if they were *simultaneously* winding cord *in opposite directions* upon two reels placed in front of us, we shall find ourselves unable to do so without a constant exercise of the attention, and even then but slowly and with difficulty; although the very same movements may be *separately* performed, or both hands may be made thus to move *in the same direction* with the greatest facility.

§ See Alfred v. Gräfe, "Klinische Analyse der Motilitäts-störungen des Auges," and v. Gräfe's "Archiv f. Ophthalmologie," Band i.-iii.

parallelism of the vertical meridians of the two eyes in certain movements, for it is found that whilst the external and internal recti merely turn the eyes outwards and inwards, without deflecting the vertical meridian, the superior and inferior recti, in consequence of the obliquity of their muscle planes, not only rotate the eye respectively upwards and downwards, but deflect the upper extremity of the vertical meridian, the former inwards, the latter outwards. But the oblique muscles also deflect the vertical meridian, the superior turning the upper extremity of the vertical meridian inwards, the inferior outwards, and therefore by co-operating with the recti, are able to preserve the parallelism of the vertical meridians of the two eyes, as shown in the following table:

Movement	Is effected by the
Upwards	Superior rectus, aided by the inferior oblique.
Downwards	Inferior rectus, aided by the superior oblique.
Inwards	Internal rectus.
Outwards	External rectus.
Upwards and inwards	Superior and internal recti muscles, aided by the inferior oblique.
Upwards and outwards	Superior and external recti muscles, aided by the inferior oblique.
Downwards and inwards	Inferior and internal recti muscles, aided by the superior oblique.
Downwards and outwards	Inferior and external recti, aided by the superior oblique.

643. On studying the voluntary movements of the Eyeballs we are led to perceive that they are not so much *symmetrical* as *harmonious*—that is to say, the corresponding muscles on the two sides are rarely in action at once; whilst such a harmony or *consent* exists between the actions of the muscles of the two orbits, that they work to one common purpose—namely, the direction of both eyes towards the required object. They may be arranged under two groups; the first comprising those which are alike harmonious and symmetrical; the second including those which are harmonious but not symmetrical. To the *first* group belong the following:—1. *Both* eyeballs are *elevated* by the contraction of the two Superior Recti.—2. *Both* eyeballs are *depressed* by the conjoint action of the Inferior Recti muscles.—3. *Both* are drawn directly *inwards*, or *inwards* and *downwards*, as when we look at an object placed on or near the nose: this movement is effected by the action of the Internal Recti of the two sides, with or without the Inferior Recti. It is evidently symmetrical, but might seem at first sight not to be harmonious, because the eyes do not move together towards one side or the other; it is, however, really harmonious, since it directs their axes towards the same point.*—Now it is to be observed, with regard to these movements, that we can never effect them in antagonism with each other, or with those of other muscles. We cannot, for example, raise one eye and depress the other; nor can we raise or depress one eye, when we adduct or abduct the other. The explanation of this will be found in the fact, that we can never, by so doing, direct the eyes to the same point.—The harmonious but unsymmetrical movements forming the *second* class, are those in which the Internal and External Recti of the two sides are made to act together, either alone, or in conjunction with the Superior and Inferior Recti.

* Some persons can effect this voluntarily to a greater extent than others; but even then they can only accomplish it by fixing the gaze upon some object situated between the eyes; and cannot call the adductor muscles into combined action in perfect darkness, or if the lids be closed. Even those who have the least power of effecting this extreme convergence, by at once directing the eyes towards a very near object, can accomplish it by looking at an object placed at a moderate distance, and gradually bringing this nearer to the nose, keeping the eyes steadily fixed upon it. The unwonted character of the movement is shown in this—that it can only be maintained, even for a short time, by a strong effort, producing a sense of fatigue.

They are as follows :—4. *One* eye is made to revolve directly *inwards* by the action of its Internal Rectus, whilst *the other* is turned *outwards* by the action of its External Rectus.—5. *One* eye is made to revolve *upwards* and *inwards*, by the conjoint action of the Superior and Internal Recti; *the other upwards* and *outwards*, by the conjoint action of the Superior and External Recti.—6. *One* eye is made to revolve *downwards* and *inwards*, by the conjoint action of the Inferior and Internal Recti; *the other*, *downwards* and *outwards*, by the conjoint action of the Inferior and External Recti.—In these movements, *two different* muscles, the External and Internal Recti, are called into action on the two sides, with or without the superior and inferior Recti; but they are so employed for the purpose of directing the axes of the eyes towards *the same* point; and although, as just noticed, we can put the two Internal Recti in action together, we cannot voluntarily cause the two External Recti to contract together, it not being possible that any object should be in such a position as to require this action for the direction of the axes of the eyes towards it.

644. The greater number of the foregoing movements may be performed unconsciously to ourselves, in obedience to a Voluntary determination to keep the direction of the eyes fixed, instead of to give motion to the eyeballs. Thus, if we gaze steadily at an object in front of us, and then depress the head forwards on its transverse axis, the eyeballs roll upwards upon their transverse axes (1) by the action of the Superior Recti, without our being aware of it; so if, whilst still maintaining the same fixed gaze, we raise the head into the vertical position and then depress it backwards, the eyeballs are rolled downwards (2) by the action of the Inferior Recti; if, under the same conditions, the head be made to rotate on its vertical axis from side to side, the eyeballs will be made to roll on their vertical axes in the contrary directions by the External and Internal Recti (3) of the two sides respectively; so, by causing the head to move obliquely in the opposite directions, the reverse oblique movements (4 and 5) of the eyeballs are made to take place by the continued fixation of the vision upon the same object. To these we have to add one more action, which cannot be called forth in any other mode—namely, that rotation of the eyes upon their antero-posterior axes, which takes place probably by the instrumentality of the Oblique muscles, when we incline the head to one side or the other by rotating it upon its antero-posterior axis. In all these movements, as in the preceding, the Will directs the *result*; and there is no other difference between them, than that which arises out of our consciousness of a change in the one case, and our unconsciousness in the other. It may here be remarked that Prof. Helmholtz* has recently adopted the same view as that just expressed in regard to the nature of the volitional direction and the influence of the guiding sensations; in corroboration of which he further mentions the important fact ascertained by Donders and himself, that by the use of a prism before one eye, *both* eyes may be made to move *outwards*, or one up and the other down—still under the same fundamental law.—The truly involuntary movement of the eyeballs, however, are performed under very different conditions; there being here no purposive direction or fixation of the gaze; and the muscular contractions not being determined by visual sensations, but being called forth by nerve force excited in some remote part. Of this we have an example in the normal revolution of both eyes upwards and inwards, which takes place in the acts of coughing, sneezing, winking, &c.; but far more remarkable illustrations are presented in those abnormal movements

* In his Croonian Lecture, "Proceedings of the Royal Society," April 14, 1864, p. 193.

of the eyeballs occurring in Convulsive diseases, in which there is neither harmony nor symmetry.

645. It has been stated to be a condition of single and distinct vision, that the *usual* axes of the eyes should be directed towards the object, in order that its picture should be thrown upon the parts of the two retinæ which are *accustomed* to act together (§ 566) ; but as this cannot take place without the guidance of visual sensations, the movements of the eyeballs are wanting in harmony whenever the visual power has been deficient from birth. This is most remarkably the case, where the deficiency has been so complete that not even light can be distinguished; but the movements are frequently very far from being harmonious, in cases of congenital cataract, where a considerable amount of light is evidently admitted, but where no distinct image can be formed ; and in such cases, the movements are most harmonious where the object is bright or luminous, and more vivid impressions are therefore made upon the retinæ. It is no objection to this doctrine to say, that persons who have *become* blind may still move their eyes in a harmonious manner; since the habit of the association of particular movements having been once acquired, the guidance of the muscles may be affected by sensations derived from themselves, in the manner in which it takes place in the laryngeal movements of the deaf and dumb; and, as a matter of fact, a want of consent may often be observed where the blindness is total. The peculiar 'vacant' appearance, which may be noticed in the countenances of persons completely deprived of sight by amaurotic or other affections, which do not alter the external aspect of the eyes, seems to result from this—that their axes are *parallel*, as if the individual were looking into distant space, instead of presenting that slight convergence which must always exist between them, when the eyes are fixed upon a definite object. This convergence, which is of course regulated by the Internal Recti, varies in degree according to the distance of the object; and it is astonishing how minute an alteration in the axes of the eyes becomes perceptible to a person observing them. For instance, A sees the eyes of B directed towards his face, but he perceives that B is *not looking* at him ; he knows this by a sort of intuitive interpretation of the fact, that his face is not the point of convergence of B's eyes. But if B, who might have been previously looking at something nearer or more remote than A's face, fix his gaze upon the latter, so that the degree of the convergence of the axes is altered, without the general direction of the eyes being in the least affected, the change is at once perceived by the person so regarded; and the *eyes* of the two then *meet*.—It is an interesting confirmation of the principles here advocated, that when binocular vision cannot be obtained by directing the true axes of the eyes towards the object, as happens when an opaque spot exists upon the centre of the cornea, or an artificial pupil has been formed at the margin of the iris, there is an automatic tendency to the neutralization of the mischief, by such an action of the muscles as shall turn the *virtual* axis of the affected eye (that is, the axis in which the rays most directly enter the globe) towards the object, thus producing Strabismus, but *not* Double Vision.

3. *Energy and Rapidity of Muscular Contraction.*

646. The energy of Muscular contraction is of course to be most remarkably observed in those instances in which the continual exercise of particular parts has occasioned an increased determination of blood towards them, and in consequence a permanent increase of their bulk (§ 330). This has been the case, for example, with persons who have gained their livelihood by exhibiting feats of strength. Much will, of course, depend on the mechanically-advan-

tageous application of muscular power; and in this manner effects may be produced, even by persons of ordinary strength, which would not have been thought credible. In lifting a heavy weight in each hand, for example, a person who keeps his back perfectly rigid, so as to throw the pressure vertically upon the pelvis, and only uses the powerful extensors of the thigh and calf, by straightening the knees (previously somewhat flexed), and bringing the leg to a right angle with the foot, will have a great advantage over one who uses his lumbar muscles for the purpose. A still greater advantage will be gained by throwing the weight more directly upon the loins, by means of a sort of girdle, shaped so as to rest upon the top of the sacrum and the ridges of the ilia; and by pressing with the hand upon a frame, so arranged as to bring the muscles of the arms to the assistance of those of the legs: in this manner, a single man of ordinary strength may raise a weight of 2000 lbs.; whilst few who are accustomed to such exertions, can lift more than 300 lbs. in the ordinary mode. A man of great natural strength, however, has been known to lift 800 lbs. with his hands: and the same individual performed several other curious feats of strength, which seem deserving of being here noticed. "1. By the strength of his fingers, he rolled up a very large and strong pewter dish. 2. He broke several short and strong pieces of tobacco-pipe with the force of his middle finger, having laid them on the first and third finger. 3. Having thrust in under his garter the bowl of a strong tobacco-pipe, his legs being bent, he broke it to pieces by the tendons of his hams, without altering the bending of the knee. 4. He broke such another bowl between his first and second fingers, by pressing them together sideways. 5. He lifted a table six feet long, which had half a hundred weight hanging at the end of it, with his teeth, and held it in that position for a considerable time. It is true, the feet of the table rested against his knees; but as the length of the table was much greater than its height, that performance required a great strength to be exerted by the muscles of his loins, neck, and jaws. 6. He took an iron kitchen poker, about a yard long, and three inches in circumference, and holding it in his right hand, he struck it on his bare left arm between the elbow and the wrist, till he bent the poker nearly to a right angle. 7. He took such another poker, and, holding the ends of it in his hands, and the middle of it against the back of his neck, he brought both ends of it together before him; and, what was yet more difficult, he pulled it straight again."* Haller mentions an instance of a man, who could raise a weight of 300 lbs., by the action of the elevator muscles of his jaw: and that of a slender girl, affected with tetanic spasm, in whom the extensor muscles of the back, in the state of chronic contraction or opisthotonos, resisted a weight of 800 lbs. laid on the abdomen with the absurd intention of straightening the body.

647. *Absolute Force of Muscle.*—The mechanical power exerted by muscle in contraction may be calculated as in any mechanical machine, by multiplying the weight lifted by the height to which it is raised. Weber obtained the following values for the muscles of a frog;—

	Weight lifted in Grammes.		Height in Mm.		Mechanical effect in Grammillimetres.
a	5		27·6		138
b	15	× by	25·1	=	376
c	25		11·45		286
d	35		6·3		220

That is to say, that 138 grammillimetres are equal to 5 grammes raised 27·6 mm. or to 27·6 grammes raised 5 mm. It will be seen from the table that the mechanical effect increases to a certain point with the weighting, and then

* Desagulier's "Philosophy," vol. ii.

gradually diminishes: it was found that different muscles had their maximum weightings.—The power of the muscles appears to vary in different animals, being greatest in proportion to their size in Insects.* The relation of the muscles of the same animal to one another is very simple, the weight which can be raised, as Professor Haughton† states, being proportional to the area of the cross section of each muscle, and may even be estimated by the cross section of the tendon that conveys its influence to a distant point; whilst it is obvious that a given weight can be raised higher in proportion to the length of the muscle. The most natural measure of the maximum of force which is exerted when the muscle is in its highest state of excitability is the amount of work it can accomplish under the influence of the strongest stimulus. But this, as is shown above, is found to vary with the degree of weighting; and it is, therefore, advantageous to adopt another measure to which the term "absolute muscle-force" may be applied.‡ This is represented by the weight, which is exactly equivalent to the contractile power of the muscle when stimulated to its utmost, or, in other words, which the muscle, when most strongly stimulated, is just incapable of raising. The absolute muscle-force for the square centimetre of the muscles of the frog was estimated by Weber at 692 grammes. Rosenthal§ gives a higher number for the muscles of the same animal, estimating it at from 2300 to 3000 grammes per square centimetre of cross section for the adductor magnus and semi-membranosus, and from 1000 to 1200 grammes for the gastrocnemius; whilst for the square centimetre of the muscle of man, Henke and Knorz have estimated it at from 6000 to 8000 grammes; and Koster‖ at about 10,000 grammes per square centimetre for the muscles of the leg, and 7400 for those of the arm. Haughton's estimate¶ agrees very closely with those of Henke and Knorz, since he considers the absolute muscle-force of the muscles of the human arm to be 94·7 lbs., of the leg to be 110·4 lbs., and of the abdomen to be 107 lbs. for the square inch of sectional area, which reduced to French measure** would amount to about 7700 grammes for the square centimetre. Mr. H. F. Baxter†† found from his experiments that one grain of frog's muscle is on the average capable of raising a weight of 608 grains through a space of 1-63rd of an inch, though considerable differences exist in regard to sex, age, and general condition of the animal. Thus he found that whilst one grain of the muscle of male frogs could raise 656 grains, one grain of the muscle of female frogs could only raise 579 grains. Again in March and April one grain of frog's muscle raised 445 grains $\frac{1}{63}$ of an inch high, in June and July 608 grains.‡‡ This agrees with the observation of Schmulewitsch,§§ that within certain limits the higher the temperature of muscle, the more work is it able to perform with equal weighting and stimulus. Fick‖‖ finds the power possessed by one grain of frog's muscle to be 5000 millimetre-grammes for one single contraction. Haughton¶¶ estimates that one ounce of the human heart

will lift 20·576 lbs. through a height of one foot per minute, and that one lb. av. weight of human muscle is capable of lifting 1·56 ton through one foot before it is exhausted. Mr. Baxter's experiments also show the interesting circumstance that whilst there is a loss of weight in the animal during prolonged muscular contraction, there is an increase of weight in the individual muscles experimented on.—It is to be recollected, that the mechanical application of the power developed by muscular contraction to the movement of the body, is very commonly disadvantageous as regards *force:* being designed to cause the part moved to pass over a much greater *space* than that through which the muscle contracts. Thus the temporal muscle is attached to the lower jaw at about one-third of the distance between the condyle and the incisors; so that a shortening of the muscle to the amount of half an inch, will draw up the front of the jaw through an inch and a half; but a power of 900 lbs. applied to the muscle, would be required to raise 300 lbs. bearing on the incisors. In the case of the fore-arm and leg, the disproportion is much greater; the points of attachment of the muscles by which the knee and elbow-joints are flexed and extended, being much closer to the fulcrum, in comparison with the distance of the points on which the resistance bears. Professor Haughton has also shown that there is a loss in the force applied by the muscles of various animals in consequence of the friction of their tendons, which amounts in a man to 35 per cent., in the mastiff to 41 per cent., and in the kangaroo to 61 per cent. It may be instructive to append here the estimates made by different observers of the amount of work that a man weighing about 150 lbs. can with vigorous exertion accomplish in the course of a day of eight hours. The French assume as a work-unit the force that is requisite to raise one kilogramme (= 2·2 lbs.) one metre (= 39·37 in.) high in one second of time:—

Kind of labour.	Amount of work in foot-tons.	Authority.
Pedestrians	353	Haughton.
Pile-driving	312	Coulomb.
Pile-driving	352	Lamande.
Turning a winch	374	Coulomb.
Porters carrying goods and returning unloaded	325	„
Porters always loaded	303	„
Porters carrying wood upstairs and returning unloaded	381	„
Paviours at work	352	Haughton.
Prisoners at shot-drill	310	„

The mean of these estimates is 340·2 ft.-tons, or 762,048 ft.-pounds = 105,605 kilogrammetres, which closely accords with the estimate of Professor Donders.* In his Address at the Meeting of the British Association at Oxford, Professor Haughton estimated the daily external work of a working man at 353·74 foot-tons and adds 133 foot-tons for the work requisite to maintain the circulation and respiration. Ranke† gives the following table from Redtenbacher:—

The amount of work accomplished in eight hours by	Kilogr. in 8 hours.
1. Man, weighing on the average 70 kilog., working without machine	316,800
„ with a lever (Hebel)	158,400
„ with a windlass (Kurbel)	184,320
„ with a whinsey or gin	207,360
„ with a treadwheel	241,920
„ with an inclined plane, 24°	345,600
2. Horse, weighing on the average 280 kilog., working without a machine	2,102,400
„ with a gin	1,152,000

* See Dr. Moore's translation of his Paper in Humphry and Turner's "Journal of Anatomy," vol. i. 1867, p. 168.

† "Grundzüge der Physiologie," 1868.

The amount of work accomplished in eight hours by	Kilogr. in 8 hours.
3. Ox, weighing on the average 280 kilog., without machine	1,382,400
„ with a gin	1,123,200
4. Mule, weighing on the average 230 kilog., without machine	1,497,600
„ with gin	777,600
5. Ass, weighing on the average 168 kilog., without machine	864,000
„ with gin	316,800

Reducing these results to a general measure for a given weight, Ranke estimates that—

1 kilog. of human muscle works in 1 sec., without machine,					0·157 kilog.
„	ox	„	„	„	0·172 „
„	ass	„	„	„	0·178 „
„	mule	„	„	„	0·222 „
„	horse	„	„	„	0·261 „

He calculates eight hours' walking to be equivalent to 200,000 kilogr.

648. *Sources of Muscular Force.*—Muscle has been defined by an able chemist to be a machine by which heat is converted into mechanical force; and the results of numerous recent researches tend to show that the source of the primary heat is to be looked for in the oxidation of both the nitrogenous and of the non-nitrogenous constituents of the blood; the combination taking place partly within the bloodvessels, but chiefly in those portions of the blood which, escaping from the vessels, supply the tissue with the materials requisite for its nutrition. That nitrogenous substances are oxidized during muscular exertion is sufficiently proved by the necessity that exists for their free supply in groups of men, as navvies, prizefighters, &c., who have to maintain severe and protracted exertion, as well as by the fact ascertained by Parkes (§ 367) and Flint (§ 367) that a slight increase in the amount of the products of the disintegration of the nitrogenous constituents of the body does take place during exercise, becoming apparent by an increased elimination of nitrogen some hours after the exercise has been taken, whether the diet have contained a regulated amount of nitrogen, or has been wholly restricted to non-nitrogenous substances. That the force daily exerted by the muscles of a labouring man is, however, not exclusively derived from the combustion of the nitrogenous constituents of his muscles or of his blood, is proved by the circumstance that the elimination of urea, which may be regarded as the final product in the animal body of the decomposition of the albuminoid compounds, is not proportional to the amount of force expended;* and, secondly, by the fact that even allowing a margin for errors of calculation and experiment, the absolute quantity of nitrogen eliminated by the body represents an amount of albuminous material the combustion of which is insufficient to account for the muscular force that is generated with even moderate exertion. That the oxidation of the non-nitrogenous materials of the blood occurs during work, to furnish the heat which the muscles transform into mechanical force, is shown, first, by the greatly increased amount of carbonic acid contained in the venous blood of a contracting muscle, as compared with a muscle at rest (Sczelkow); secondly, by the increased elimination of carbonic acid and water that occurs during exercise (E. Smith, § 311); thirdly, by

* In his recent Memoir on the 'Source of Muscular Power' ("Journ. of Anat. and Physiol.," vol. xii. 1878, p. 141), Austin Flint states that in his experiments upon a man walking 317½ miles in five consecutive days, who at the beginning of the five days had no superfluous fat, the loss of weight was actually 3·45 lbs., while the total amount of nitrogen discharged from the body in the urine and fæces in excess of the nitrogen of the food taken for these five days, assuming that three parts of nitrogen represent 100 parts of muscular substance, as has been shown by analysis to be the fact, amounted to 3·037 lbs. of muscular substance. Hence he argues that in excessive muscular work a certain amount of muscular substance is consumed.

the fact that in some animals, as in bees (Verloren), as well as in man, (Fick, Parkes) a considerable amount of exertion can be temporarily undertaken on a diet containing little or no nitrogen, as sugar and fat, though it has been clearly shown that if the diet be exclusively confined to non-nitrogenous material, weakness and weariness soon supervene, quickly followed by complete muscular exhaustion (Hammond, Savory, Parkes). It may be remarked, also, that in those nations, and in those animals, that are well supplied with nitrogenous compounds in their food, a superior physical condition is produced, enabling them to maintain severe exertion for a longer period, and also to exert, when occasion may require, more vigorous effort for a shorter period, than those whose diet is of a poorer quality, or contains less nitrogen in an easily assimilable form. The precise seat of the oxidation cannot be held to be decisively ascertained, and some, but not very satisfactory evidence has been brought forward to show that it takes place within the vessels. The chemical facts connected with the contraction of muscle have been ingeniously woven by Hermann* into the following theory. He supposes that muscle contains a store of a complex nitrogenous material in a state of solution. It is unstable, and in the act of disintegration developes force. The products of its disintegration are, *inter alia*, carbonic acid, paralactic acid (possibly as Ranke believes, sugar and fat), and an albuminous compound which in the living muscle is gelatinous, but soon coagulates into a solid substance (Myosin). When at rest the disintegration proceeds slowly, but it is rendered more energetic by elevation of temperature within certain limits, and is induced instantly by certain "irritants." As the muscle substance is gradually consumed by exertion, it is requisite for the maintenance of its characteristic properties that a constant circulation of blood should take place through its vessels, by which means not only may oxygen and fresh supplies of nutritive material be brought to it, but the products of its disintegration, the presence of which seriously impairs its contractile powers, may be removed.† The power of the muscles appears to be capable of being increased by the passage of a continuous electrical current through the nerves supplying them.‡ Thus, Dr. Poore has shown that in a case where a man could hold his arm outstretched for six minutes, when the current was used he could go on for thirteen minutes. So also eight successive squeezes of the dynamometer without galvanism gave 388 lbs., and the same number with galvanism 477 lbs. Similar observations have been made by Heidenhain and Remak, who have termed such currents 'refreshing' or 'restorative.'

649. The rapidity of the changes of position of the component particles of muscular fibres, may, as Dr. Alison justly remarks,§ be estimated, though it can hardly be conceived, from various well-known facts. The pulsations of the heart can sometimes be distinctly numbered in children at more than 200

§ "Cyclopædia of Anatomy and Physiology," Art. 'Contractility.'

in the minute; and as each contraction of the ventricles occupies only half the time of the whole pulsation, it must be accomplished in 1-400th of a minute, or 3-20ths of a second. Again, it is certain that, by the movements of the tongue and other organs of speech, 1500 letters can be distinctly pronounced by some persons in a minute: every one of these must require a separate contraction of muscular fibres; and the production and cessation of each of the sounds implies that each separate contraction must be followed by a relaxation of equal length; each contraction, therefore, must have been effected in 1-3000th part of a minute, or in 1-50th of a second. Haller calculated that, in the limbs of a dog at full speed, muscular contractions must take place in less than 1-200th of a second, for many minutes at least in succession.—All these instances, however, are thrown into the shade by those which may be drawn from the class of Insects. The rapidity of the vibrations of the wings may be estimated from the musical tone which they produce; it being easily ascertained by experiments what number of vibrations are required to produce any note in the scale (§ 598). From these data, it appears to be the necessary result, that the wings of many Insects strike the air *many hundred* or even *many thousand* times in every *second*.—The minute precision with which the degree of muscular contraction can be adapted to the designed effect is in no instance more remarkable than in the Glottis. The musical pitch of the tones produced by it is regulated by the degree of tension of the *chordæ vocales*, which are possessed of a very considerable degree of elasticity (§ 656). According to the observations of Müller,* the average length of these, in the male, in a state of repose, is about 73-100ths of an inch; whilst in the state of greatest tension it is about 93-100ths; the difference being therefore 20-100ths, or *one-fifth* of an inch: in the female glottis, the average dimensions are about 51-100ths and 63-100ths respectively; the difference being thus about *one-eighth* of an inch. Now the natural compass of the voice in most persons who have cultivated the vocal organ may be stated at about two octaves, or 24 semitones. Within each semitone a singer of ordinary capability could produce at least ten distinct intervals; so that of the total number, 240 is a very moderate estimate. There, must, therefore, be at least 240 different states of tension of the Vocal Cords, every one of which is producible by the will, without any previous trial; and the *whole* variation in the length of the cords being not more than one-fifth of an inch, even in man, the variation required to pass from one interval to another will not be more than 1-1200th of an inch. And yet this estimate is much below that which might be truly made from the performances of a practised vocalist.†

CHAPTER XVI.

OF THE VOICE AND SPEECH.

1. *Of the Larynx, and its Actions.*

650. THE sounds produced by the Organ of Voice constitute the most important means of communication between Man and his fellows; and the power of Speech has, therefore, a primary influence, as well on his physical condition, as on the development of his mental faculties. It is necessary to

* "Elements of Physiology," Baly's Translation, p. 1018.

† It is said that the celebrated Madame Mara was able to sound 100 different intervals between each tone. The compass of her voice being at least three octaves, or 21 tones, the total number of intervals was 2100, all comprised within an extreme variation of one-eighth of an inch; so that it might be said that she was able to determine the contractions of her vocal muscles to nearly the *seventeen-thousandth* of an inch.

bear in mind that Vocal sounds, and Speech or articulate Language, are two things entirely different; and that the former may be produced in great perfection, where there is no capability for the latter. Hence we might at once infer, that the instrument for the production of vocal sounds is distinct from that by which these sounds are modified into articulate speech; and this we easily discover to be the case, the voice being unquestionably produced in the *larynx*, whilst the modifications of it, by which language is formed, are effected for the most part in the *oral cavity*.—The structure and functions of the former, then, first claim our attention. It will be remembered that the Trachea is surmounted by a stout cartilaginous annulus, termed the *Cricoid* cartilage (Figs. 300, 301, A B, Fig. 302, *r u x w*); which serves as a foundation for the superjacent mechanism. This is embraced (as it were) by the *Thyroid* (Figs. 300, 301, E C G, Fig. 302, G E H), which is articulated to its sides by the lower horns (Figs. 300, 301, c), round the extremities of which it may be considered to turn as on a pivot. In this manner, the lower front border of the Thyroid cartilage which is ordinarily separated by a small interval (Figs. 302, 301, *m n*) from the upper margin of the Cricoid, may be made to approach it or to recede from it; as any one may easily ascertain by placing his finger against the little depression which may be readily felt externally, and observing its changes of size, whilst a range of different tones is sounded; for it will then be noticed that, the higher the note, the more the two cartilages are made to approximate, whilst they separate in proportion to the depth of the tones.* Upon the upper surface of the back of the Cricoid, are seated the two small *Arytenoid* cartilages (Figs. 301, 302, F F); these are fixed in one direction by a bundle of strong ligaments, which tie them to the back of the cricoid; but they have some power of moving in other directions, upon a kind

* In making this observation, it is necessary to put out of view the general movement of the Larynx itself, which the finger must be made to follow up and down.

of articulating suface. The direction of the surface, and the mode in which these cartilages are otherwise attached, cause their movement to be a sort of rotation in a plane which is nearly horizontal, but partly downwards; so that their vertical planes may be made to separate from each other, and at the same time to assume a slanting position. This change of place will be better understood when the action of the muscles is described. To the lower part of the anterior surface of the Arytenoid cartilages are attached the *chordæ vocales* or Vocal Ligaments (Fig. 300, E F, Fig. 302, T V), which stretch across to the front of the Thyroid cartilage; and it is upon the condition and relative situation of these ligaments that their action depends. It is evident that they may be rendered more or less tense by the movement of the Thyroid cartilage

FIG. 300

External and Sectional views of the *Larynx*:—A *n* B, the cricoid cartilage; E C G, the thyroid cartilage; G, its upper horn; C, its lower horn, where it is articulated with the cricoid; F, the arytenoid cartilage; E F, the vocal ligament; A K, crico-thyroideus muscle; F *e m*, thyro-arytenoideus muscle; X *e*, crico-arytenoideus lateralis; *s*, transverse section of arytenoideus transversus; *m n*, space between thyroid and cricoid; B L, projection of axis of articulation of arytenoid with thyroid.

thus described; being tightened by the depression of its front upon the Cricoid cartilage, and slackened by its elevation. On the other hand, they may be brought into more or less close apposition by the movement of the Arytenoid cartilages; being made to approximate nearly, or to recede in such manner as to cause the rima glottidis to assume the form of a narrow V, by the revolution of these cartilages.—We shall now inquire into the actions of the muscles upon the several parts of this apparatus; and first into those of the larynx alone.

651. The depression of the front of the Thyroid cartilage, and the consequent *tension* of the Vocal Ligaments, is occasioned by the conjoint action of the *Crico-thyroidei** (Fig. 301 A K) on both sides; and the chief antagonists to these are the *Thyro-arytenoidei* (Fig. 300, F *m*, Fig. 302, V *k f*), which draw the front of the thyroid back towards the arytenoid cartilages, and thus *relax* the vocal ligaments. These two pairs of muscles may be regarded as the

* For a careful investigation in regard to the precise mode in which the crico-thyroid acts see Jelenffy, Pflüger's "Archiv," 1873, vol. vii. p. 86.

principal governors of the *pitch* of the notes, which, as we shall hereafter see, is almost entirely regulated by the tension of the ligaments; their action is assisted, however, by that of other muscles presently to be mentioned.*—The arytenoid cartilages are made to diverge from each other, by means of the *Crico-arytenoidei postici* (Fig. 302 N *l*) of the two sides, which proceed from their outer corners, and turn somewhat round the edge of the Cricoid, to be attached to the lower part of its back; their action is to draw the outer corners backwards and downwards, so that the points to which the vocal ligaments are attached are separated from one another and the rima glottidis is thrown *open*. This will be at once seen from the succeeding diagram, in which the direction of traction of the several muscles is laid down.—The action of these muscles is partly antagonized by that of the *Crico-arytenoidei laterales* (Fig. 302, N X), which run forwards and downwards from the outer corners of the Arytenoid cartilages, and whose contraction tends to bring their anterior points into the same straight line, depressing them at the same time, so as thus to *close* the glottis. These muscles are assisted by the *Arytenoideus transversus* (Fig. 302), which connects the posterior faces of the Arytenoid cartilages, and which, by its contraction, draws them together. By the conjoint action, therefore, of the Crico-arytenoidei laterales and of the Arytenoideus transversus, the whole of the adjacent faces of the Arytenoid cartilages will be approximated, and the points to which the vocal ligaments are attached will be depressed.—But if the Arytenoideus be put in action in conjunction with the Crico-arytenoidei postici, the tendency of the latter to separate the Arytenoid cartilages being antagonized by the former, its backward action only will be exerted; and thus it may be caused to aid the Crico-thyroidei in rendering tense the vocal ligaments. This action will be further assisted by the *Sterno-thyroidei*, which tend to depress the Thyroid cartilage by pulling from a fixed point below;† and the *Thyro-hyoidei* will be the antagonists of these, when they act from a fixed point above, the Os Hyoides being secured by the opposing contraction of several other muscles.—The respective actions of these muscles will be best comprehended by the following table:—

FIG. 302.

* Dr. P. Martyn has adduced various observations to show that the Thyroid body exerts an important influence on the pitch of the notes by giving a certain firmness, rigidity, and tension to the larynx. He also suggests that this body may act as a *loader*, rendering the vibrations of the vocal cords slower and longer, and the tone in consequence fuller, louder, and deeper, thus compensating for the small size of the larynx; finally he believes that it aids, by its changes in shape bulk and density, in producing the wonderful qualities of modulation and expression peculiar to the human voice. See "Proceedings of the Royal Society," vol. viii. p. 315.

† These are not usually reckoned among the principal muscles concerned in regulating the voice; but that they are so, any one may convince himself by placing his finger just above the sternum, whilst he is sounding high notes; a strong feeling of muscular tension is then at once perceived.

Govern the Pitch of the Notes.

Antagonists.

Crico-Thyroidei Sterno-Thyroidei	.....	Depress the front of the Thyroid cartilage on the Cricoid, and *stretch* the vocal ligaments; assisted by the Arytenoideus and Crico-arytenoidei postici.
Thyro-Arytenoidei Thyro-Hyoidei	.....	Elevate the front of the Thyroid cartilage, and draw it towards the Arytenoids, *relaxing* the vocal ligaments.

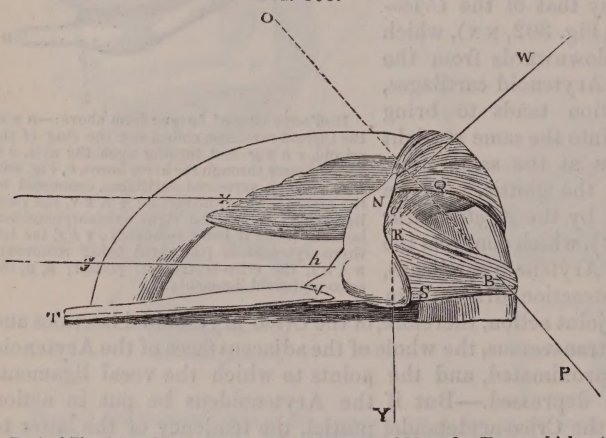
Govern the Aperture of the Glottis.

Antagonists.

Crico-Arytenoidei postici	.....	*Open* the Glottis.
Crico-Arytenoidei laterales Arytenoideus transversus	.....	Press together the inner edges of the Arytenoid cartilages, and *close* the Glottis.

652. The muscles which stretch or relax the Vocal cords are entirely concerned in the production of Voice: those which govern the aperture of the Glottis have important functions in connection with the Respiratory actions in general, and stand as guards (so to speak) at the entrance to the lungs. These separate actions are easily made evident. In the ordinary condition of rest, it seems probable that the Arytenoid cartilages are considerably separated from each other; so as to cause a wide opening to intervene between their inner faces and between the vocal ligaments, through which the air freely passes; and the vocal ligaments are at the same in a state of complete relaxation.—We can close the aperture of the Glottis by an exertion of the will, during either inspiration or expiration; and its closure by an automatic impulse forms part of the acts of Coughing and Sneezing (§ 280), besides giving rise to those more prolonged impediments to the ingress and egress of air, which have been already noticed as resulting from disordered states of the Nervous system. With these actions, the muscles which regulate the tension of the vocal ligaments have nothing to do; and we have seen that they are performed by the instrumentality of the Pneumogastric or proper Respiratory nerve (§ 276). The appearances which present themselves when the interior of the Larynx is examined during life are, according to Professor Czermak, that in the almost semi-lunar space bounded by the posterior wall of the Pharnyx (Fig. 304) and the base of the tongue, the upper curved edge of the epiglottis (*e*) is seen, its lateral portions just touching the posterior pharnygeal wall, and its central portion arching forwards, so as to leave an interval for the passage of air in the median line.

Fig. 303.



Part of Fig. 302 enlarged, to show the *Direction of Muscular Forces* which act on the Arytenoid cartilage: N V S, the right Arytenoid cartilage; T, V, its vocal ligament; B R S, bundle of ligaments uniting it to Cricoid; O P, projection of its axis of articulation; *h g*, direction of the action of the Thyro-arytenoideus; N X, direction of Crico-arytenoideus lateralis; N W, direction of Crico-arytenoideus posticus; N Y, direction of Arytenoideus transversus.

Near the centre of the cleft between the upper border of the epiglottis and the walls of the pharynx, a tranverse band or cushion (*c*) is also seen, of a reddish colour, and formed by the edge of the fold of mucous membrane sustained between the two separated arytenoid cartilages (*aa*). The anterior outline of the fold is concave in front, and forms with the superior border of the epiglottis, which is concave behind and situated a little higher, a narrow transversely-elliptical fissure. If the vowel *a* be now sounded as in *ah* or *eh*, the semilunar space behind the base of the tongue is enlarged, the epiglottis rises and separates from the posterior wall of the pharynx, the glottis becomes widely opened, and a considerable portion of the anterior wall of the trachea can be perceived. A small rounded swelling situated to the outer side of the tubercles of Santorini, which was previously concealed by the lateral border of the epiglottis, now also comes into view. The movements of the arytenoid cartilages during the production of vocal sounds can be very distinctly observed by the laryngoscope, and the account given by Professor Czermak possesses considerable interest, since it fully corroborates the views derived from theory and experiment on the dead subject, which had been expressed before the introduction of the instrument. As soon as we wish to utter a sound, the two arytenoid cartilages raise themselves in the fold of mucous membrane which covers them, and approach one another with surprising mobility. This movement effects the approximation of the vocal cords, and consequently the constriction of the Glottis (Fig. 305.) The study of the mode of formation of the gravest chest-sounds is extremely difficult, on account of the arytenoid cartilages becoming elevated and rapidly approaching one another until they come almost into complete contact, whilst they bend under the border of the depressed epiglottis in such a manner that the latter, as viewed by the laryngoscope, entirely conceals the interior of the Larynx. According to Mandl* the opening of the glottis in the production of the deepest notes is ellipsoidal. During the emission of the most acute sounds, the Glottis is contracted in a linear form (Fig. 306); on each side we perceive the vocal cords, distinguished by their whitish-yellow colour, and a little to the outer side is a narrow groove indicating the position of the ventricles of Morgagni. Further outwards again are the false or superior vocal cords. These parts, with the erected arytenoid cartilages, the epiglottis pulled upwards and forwards, and the aryteno-epiglottidian ligaments, together form a short and stiff tube situated above the Glottis; the whole appearing, from the sensation we experience during the experiment,

FIG. 304.

Condition of the *Larynx* during the emission of a high or acute sound: *e*, epiglottis; *cu*, cushion of epiglottis; *i v c*, true vocal cord; *s v c*, false vocal cord.

* "Wien Acad. Sitz.-ber.," Band lxii. p. 764; and "Traité Pratique des Maladies du Larynx et du Pharynx," Paris, 1872.

to be in a state of very great tension.* That the aperture of the glottis is greatly narrowed during the production of sounds, is easily made evident to one's-self, by comparing the time occupied by an ordinary expiration, with that required for the passage of the same quantity of air during the sustenance of a vocal tone. Further, the size of the aperture is made to vary in accordance with the note which is being produced; of this, too, any one may convince himself, by comparing the times during which he can hold out a low and a high note; from which it will appear that the aperture of the glottis is so much narrowed in producing a high note, as to permit a far less rapid passage of air than is allowed when a low one is sounded. According to Kempelen no sound is elicited when the distance between the Chordæ Vocales exceeds 1-10th to 1-12th of an inch. The muscular movements concerned in the act of vocalization appear to be called-forth by the instrumentality of the motor fibres, partly derived from the Spinal Accessory nerve, which are contained in Pneumogastric (§ 452).

653. We have now to inquire what is the operation of the Vocal Cords in the production of sounds; and in order to comprehend this, it is necessary to advert to the conditions under which tones are produced by instruments of various descriptions having some analogy with the Larynx. These are chiefly of three kinds; strings, flute-pipes, and reeds or tongues.—The Vocal Ligaments were long ago compared by Ferrein to vibrating *strings;* and at first sight there might seem a considerable analogy, the sounds which both produce being elevated by increased tension. This resemblance disappears, however, on more accurate comparison; for it may be easily ascertained by experiment, that no string so short as the vocal ligaments could give a clear tone at all to be compared in depth with that of the lowest notes of the human voice; and also, that the scale of changes produced by increased tension is fundamentally different. When strings of the same length but of different tensions are made the subject of comparison, it is found that the number of vibrations is in proportion to the square-roots of the extending forces. Thus, if a string extended by a given weight produce a certain note, a string extended by four times that weight will give a note in which the vibrations are twice as rapid; and this will be the octave of the other. If nine times the original weight be employed, the vibrations will be three times as rapid as those of the fundamental note, producing the twelfth above it. Now by fixing the larynx in such a manner that the vocal ligaments can be extended by a known weight, Müller has ascertained that the sounds produced by a variation of the extending force do not follow the same ratio; and therefore the condition of these ligaments cannot be simply that of vibrating cords. Further, although a cord of a certain length, which is adapted to give out a clear and distinct note equal in depth to the lowest of the human voice, may be made by increased tension to produce all the superior notes (which, in stringed instruments, are ordinarily obtained by shortening the strings), it does not follow that a short string, which, with moderate tension, naturally produces a high note, should be able, by a diminution of the tension, to give out a deep one; for, although this might be theoretically possible, yet it cannot be accomplished in practice; since the vibrations become irregular on account of the diminished elasticity.† These considerations

* "On the Laryngoscope," Syd. Soc. Trans., 1861, pp. 37–8; see also "The Laryngoscope," by George D. Gibb, M.D., London, 1863. Morell Mackenzie, M.D., "The Use of the Laryngoscope, 3rd edit., 1869.

† Thus it would be impossible to produce good Bass notes on the strings of a Violin by diminishing their tension; the length afforded by the Violoncello or Double Bass is requisite.

are in themselves sufficient to destroy the supposed analogy; and to prove that the Chordæ Vocales cannot be reduced to the same category with vibrating strings.

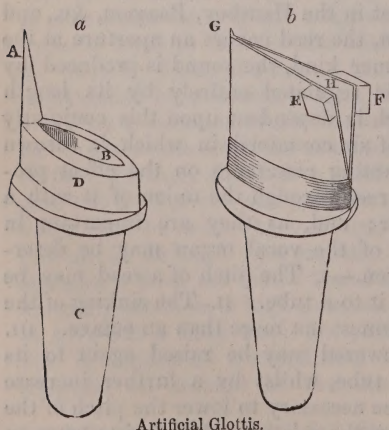
654. The next kind of instrument with which some analogy might be suspected, is the *flute-pipe*, in which the sound is produced by the vibration of an elastic column of air contained in the tube; and the pitch of the note is determined almost entirely by the length of the column, although slightly modified by its diameter, and by the nature of the embouchure or mouth from which it issues. This is exemplified in the German Flute, and in the English Flute or Flageolet; in both of which instruments the acting length of the pipe is determined by the interval between the embouchure and the nearest of the side-apertures; by opening or closing which, therefore, a modification of the tone is produced. In the Organ, of which the greater number of pipes are constructed upon this plan, there is a distinct pipe for every note; and their length increases in a regular scale. It is, in fact, with flute-pipes as with strings—that a diminution in length causes an increase in the number of vibrations, in a simply-inverse proportion; so that of two pipes, one being half the length of the other, the shorter will give a tone which is the octave above the other, the vibrations of its column of air being twice as rapid. Now there is nothing in the form or dimensions of the column of air between the larynx and the mouth, which can be conceived to render it at all capable of such vibrations as are required to produce the tones of the Human voice; though there is some doubt whether it be not the agent in the musical tones of certain Birds. The length that would be required in an open pipe to give the lowest G of the ordinary bass voice, is nearly six feet; and the conditions necessary to produce the higher notes from it, are by no means those which we find to exist in the process of modulating the human voice.

655. We now come to the third class of instruments, in which sound is produced by the vibration of *reeds* or *tongues;* these may either possess elasticity in themselves, or be made elastic by tension. The 'free' reeds of the Accordion, Concertina, Seraphine, Harmonium, &c., are examples of instruments of this character, in which the lamina vibrates in a sort of frame that allows the air to pass out on all sides of it through a narrow channel, thus increasing the strength of the blast: whilst in the Hautboy, Bassoon, &c., and in the Organ-pipes of similar construction, the reed covers an aperture at the side of one end of a pipe. In the former kind, the sound is produced by the vibration of the tongue alone, and is regulated entirely by its length and elasticity; whilst in the latter its pitch is dependent upon this conjointly with the length of the tube, the column of air contained in which is thrown into simultaneous vibration. Some interesting researches on the effect produced on the pitch of a sound given by a reed through the union of it with a tube, have been made by M. W. Weber; and, as they are important in furnishing data by which the real nature of the vocal organ may be determined, their chief results will be here given.—I. The pitch of a reed may be lowered, but cannot be raised, by joining it to a tube. II. The sinking of the pitch of the reed thus produced is at the utmost not more than an octave. III. The fundamental note of the reed thus lowered may be raised again to its pitch by a further lengthening of the tube, whilst by a further increase it is again lowered. IV. The length of tube necessary to lower the pitch of the instrument to any given point, depends on the relation which exists between the frequency of the vibrations of the tongue of the reed, and those of the column of air in the tube, each taken separately.—From these data, and from those of the preceding paragraph, it follows that if a wind instrument can, by

the prolongation of its tube, be made to yield tones of any depth in proportion to the length of the tube, it must be regarded as a flute-pipe ; whilst if its pitch can only be lowered an octave or less (the embouchure remaining the same) by lengthening the tube, we may be certain that it is a reed instrument. The latter proves to be the case in regard to the Larynx.

656. It is evident from the foregoing considerations, that the action of the Larynx has more analogy to that of *reed* instruments, than it has to that either of vibrating *strings*, or of *flute-pipes ;* and though there would seem, at first sight, to be a marked difference in character between the vocal ligaments and the tongue of any reed instrument, this difference is really by no means considerable. In a reed, elasticity is a property of the tongue itself, when fixed at one end, the other vibrating freely ; but by a membranous lamina, fixed in the same manner, no tone would be produced. If such a lamina, however, be made elastic by a moderate degree of tension, and be fixed in such a manner as to be advantageously acted on by a current of air, it will give a distinct tone. It is observed by Müller, that membranous tongues made elastic by tension may have either of three different forms :—I. That of a band extended by a cord, and included between two firm plates, so that there is a cleft for the passage of air on each side of the tongue. II. The elastic membrane may be stretched over the half or any portion of the end of a short tube, the other part being occupied by a solid plate, between which and the elastic membrane a narrow fissure is left. III. Two elastic membranes may be extended across the mouth of a short tube, each covering a portion of the opening, and having a chink left open between them.—This last is evidently the form most allied to the Human Glottis ; but it may be made to approximate still more closely, by prolonging the membranes in a direction parallel to that of the current of air, so that not merely their edges, but their whole planes shall be thrown into vibration. Upon this principle, a kind of *artificial glottis* has been constructed by Mr. Willis ; the conditions of action and the effects of which are so nearly allied to that of the real instrument, that the similar character of the two can scarcely be doubted. The following is his description of it :—"Let a wooden pipe be prepared of the Form of Fig. 307, *a*, having a foot, C, like that of an organ-pipe, and an upper opening, long and narrow, as at B, with a point, A, rising at one end of it. If a piece of leather, or still better, of sheet India-rubber, be doubled round this point, and secured by being bound round the pipe at D with strong thread, as in Fig. 307, *b*, it will give us an artificial glottis with its upper edges G H, which may be made to vibrate or not, at pleasure, by inclining the planes of the edges. A couple of pieces of cork, E F, may be glued to the corners, to make them more manageable. From this machine various notes may be obtained, by stretching the edges in the direction of their length G H ; the notes rising in pitch with the increased tension, although the length of the vibrating edge is increased. It is true that a scale of notes equal in extent to that of the human voice cannot be obtained from edges of leather ; but this scale is much greater in India-rubber than in leather, and the elasticity of them both

Fig. 307.



Artificial Glottis.

is so much inferior to that of the vocal ligaments, that we may readily infer that the greater scale of the latter is due to its greater elastic powers." By other experimenters the tissue forming the middle coat of the arteries has been used for this purpose, in the moist state, with great success; with this, the tissue of the vocal ligament is nearly identical. It is worthy of remark, that, in all such experiments, it is found that the two membranes may be thrown into vibration, when inclined *towards* each other in various degrees, or even when they are in parallel planes, and their edges only approximate; but that the least inclination *from* each other (which is the position the vocal ligaments have during the ordinary state of the glottis (§ 651–652), completely prevents any sonorous vibrations from being produced.

657. The pitch of the notes produced by membranous tongues may be affected in several ways. Thus, an increase in the strength of the blast, which has little influence on metallic reeds, raises *their* pitch very considerably; and in this manner the note of a membranous reed may be raised by semitones, to as much as a fifth above the fundamental. The addition of a pipe has nearly the same effect on their pitch, as on that of metallic reeds; but it cannot easily be determined with the same precision. Several different notes may be produced with a pipe of the same length; but there is a certain length of the column of air, which is the one best adapted for each tone. It has been recently ascertained, moreover, that the length of the pipe prefixed to the reed has a considerable influence on its tone, rendering it deeper in proportion as it is prolonged, down to nearly the octave of the fundamental note; but the pitch then suddenly rises again, as in the case of the tube placed beyond the reed. The researches of Müller, however, have not succeeded in establishing any very definite relation between the lengths of the two tubes in regard to their influence on the pitch of the reed placed between them. Oertel* has shown by the stroboscopic method of observation† that in ordinary chest tones the vocal cords vibrate throughout their whole length and breadth, in such a way that the excursions of the various points of the cord increase with their distance from the outer border.

658. From the foregoing statements, it appears that the true theory of the Voice may now be considered as well established, in regard to this essential particular—that the sound is the result of the vibrations of the true vocal cords, which take place according to the same laws with those of metallic or other elastic tongues: and that the pitch of the notes is chiefly governed by the tension of these laminæ. With respect, however, to the mode and degree in which these tones are modified by the shape of the air-passages both above and below the larynx, by the force of the blast and by other concurrent circumstances, little is certainly known; but no doubt can be felt that these

* "Centralblatt," 1878, pp. 81 and 89.

† This consists in observing a body having a rapid but unknown rate of vibration at intervals which can be regulated to correspond to the unknown rate. This object can be accomplished by illuminating the vibrating body by a rapid series of electrical sparks, or by looking at it through holes in the edge of a revolving disk, or through a perforated disk attached to a tuning-fork. If the rate of the observations coincides with that of the vibrating body, the latter, being observed always in the same phase of its vibration, presents the appearance owing to the persistence of the impressions on the retina of a body perfectly at rest. If the rate of the observations be a little slower than that of the vibrating body, the latter, being at each observation in a somewhat more advanced phase of its movement, will appear to execute its vibration at a rate corresponding to the difference between the rates of observation and vibration. Thus a body vibrating two hundred times in a second, seen through a stroboscopic apparatus, giving two hundred and one observations in a second, will appear to vibrate once in a second. Thus by knowing the rate of the observations, and noting the rate of the apparent stroboscopic movement, the rate of the vibrating body may be determined.

modifications are of great importance, when we observe the great amount of muscular action which takes place consentaneously with the production of vocal tones, and which seems designed to alter the length and tension of the various parts of the *vocal tube*, so that they may vibrate synchronously with the *vocal cords*. Thus, during the ascent of the voice from the deeper to the higher notes of the scale, we find the whole larynx undergoing an elevation towards the base of the cranium, the thyroid cartilage being drawn up within the oshyoides, so as even to press on the epiglottis ; at the same time, the small space between the thyroid and cricoid cartilages, or crico-thyroid chink, is closed by the depression of the front of the former upon the latter (§ 651); the velum palati is depressed and curved forwards; and the tonsils approach one another. The reverse of all these movements takes place during the descent of the voice.—A very important adjunct to the production of the higher notes has been pointed out by Müller, as being afforded by the modification in the space included between the two sides of the thyroid cartilage, which is effected by the thyro-arytenoidei. He had experimentally ascertained that the introduction of a hollow plug into the upper end of the pipe beneath his artificial larynx (and therefore just below the reed), by diminishing its aperture, produced a considerable elevation of the tone. The action may be imitated in the human larynx, when made the subject of experiment, by compressing the thyroid cartilage laterally; and in this manner, the natural voice can be made to extend through a range that could otherwise be only reached by a falsetto. The influence of the prefixed and superadded tubes, in modifying the tones produced by the Human larynx, has been found by Prof. Müller not to be at all comparable to that which they exercised over the artificial larynx; the reason of which difference does not seem very apparent. It appears, however, that there is a certain length of the prefixed tube—as there is a certain distance of the vibrating laminæ, and a certain length or form of the tube above—which is most favourable to the production of each note; and the downward movement of the whole vocal organ, which takes place when we are sounding deep notes, and its rise during the elevation of the tones, have been supposed to answer the purpose of making this adjustment in the length of the trachea; but this requires the supposition that the real length of the trachea is shortened whilst it appears extended—for which there seems no foundation. It is considered by Mr. Wheatstone, that the column of air in the trachea may divide itself into 'harmonic lengths,' and may produce a *reciprocation* of the tone given by the vocal ligaments; and in this manner he considers that the falsetto notes are to be explained. It may be added that the partial closing of the epiglottis seems to assist in the production of deep notes, just as the partial covering of the top of a short pipe fixed to a reed will lower its tone; and that something of this kind takes place during natural vocalization, would appear from the retraction and depression of the tongue, which accompany the lowering of the front of the head when the very lowest notes are being sounded. The experiments of Savart have shown that a cavity which only responds to a shrill note, when its walls are firm and dry, may be made to afford a great variety of lower tones, when its walls are moistened and relaxed in various degrees. This observation may probably be applied also to the trachea.

659. The *falsetto* is a peculiar modification of the voice, differing from the 'chest-voice,' not merely in the higher pitch of its notes, but also in their quality; its tones being less ready, and more like the 'harmonic notes' of stringed and wind instruments. In some individuals, the chest-voice passes by imperceptible gradations into the falsetto, whilst in others the transition is

abrupt; and some persons can sound the same notes in the two different registers, these notes forming the upper part of the scale of the chest-voice, and the lower part of the falsetto.*—With regard to the theory of the production of the falsetto voice, there has been considerable difference of opinion amongst Physiologists; and it cannot be regarded as fully determined. By Magendie and Mayo it was maintained that these tones are produced by the vibration of the vocal cords along only part of their length, the rima glottidis being partly closed; and this explanation is consistent with the fact, that a far smaller quantity of air is required for sustaining a falsetto note, than for a note of the ordinary register, even though they should be of the same pitch. By Müller and Garcia,† again, it is asserted that in the production of the falsetto notes, merely the thin border of the glottis vibrates, since the fibres of the lateral crico-arytenoid muscle remain inactive, whilst the lips of the glottis, stretched by the horizontal bundle of the thyro-arytenoid, come in contact by their edge alone, and offer little resistance to the air. In the chest-voice, on the contrary, the contraction of the lateral crico-arytenoids gives a rotatory movement to the cartilages, and increases the depth of the surface of contact of the two ligaments, and it is to this circumstance that the peculiar amplitude of the notes of the chest-register is attributable. Mandl believes that both these doctrines are correct: and that in the production of falsetto notes, the false or upper vocal cords apply themselves to the true vocal cords in front, behind, and to the sides, so that the middle portion of the true cords alone vibrates; whilst by the contraction of the arytenoid muscles the cords are brought into close apposition‡ with each other for part of their length, their thin edges only being in vibration in the remainder. Oertel,§ again, employing the stroboscopic method of observation, finds that in falsetto tones, on the other hand, though the cords vibrate in their whole length and breadth, the vibrating surface presents a curved nodal line about one-third of the distance from the free edge to the attached border, the parts of the cord on opposite sides of the nodal line being of course in opposite phases of vibration. In very high falsetto tones a second nodal line may be observed, indicating a still further subdivision of the vibrating surface. It has been pointed out by Mr. Bishop (loc. cit.), that at the moment of transition from the 'chest-voice' to the 'falsetto-voice,' the crico-thyroid chink, which was closed during the production of the highest note of the former, suddenly opens on the production of the lowest note of the latter, thus indicating that the vocal cords are *relaxed* in the passage from the one to the other, as must be the case, if, for the production of the same note, they be only put in vibration along a part of their length; so that it would not seem improbable that the cause of those differences in the mode of transition, which have been already noticed, lies in the differences in the proportional amount of the vocal cords, which is thus thrown out of use by the partial approximation of the two lips of the rima glottidis. It is further remarked by Mr. Bishop, that, in the passage from the chest- to the falsetto-voice, the larynx descends from its previously

* Thus, a gentleman of the Author's acquaintance has a bass voice of a harsh reedy character, ranging from the D below the bass clef to the D above it (two octaves); whilst his falsetto, which is remarkable for its clearness and smoothness, ranges from the A on the highest line of the bass clef to the E in the highest space of the treble clef. Hence there are five notes common to the two registers, and the entire voice ranges through more than three octaves; but, from want of a gradual passage from one to the other, this gentleman can only sing bass parts with his chest voice, or alto parts with his falsetto, the tenor scale extending above the range of one, and below that of the other.

† "Proceedings of the Royal Society," vol. vii. p. 408.

‡ See also Ch. Bataille, "Nouv. Réch. sur la Phonation," Paris, 1861. § Op. cit.

elevated position, and gradually rises again with the ascending scale of falsetto notes; and he mentions a case of *double falsetto*, in which a third register existed, and in which the relaxation of the vocal cords and the descent of the larynx were observed at its commencement, as at the commencement of the secondary or ordinary falsetto register.* Michael's† experiments, which were chiefly made on patients affected with paralysis, seem to show that, in singing, all the glottidean muscles are brought into play, though, with different registers, different muscles are specially exerted. None of the three registers require the full action of all the muscles, but with each register one particular muscle is in full action, thus giving the register its klang tone. In the chest register the crico-arytenoideus lateralis is chiefly in action, and the whole vocal cord vibrates; in the middle and falsetto registers only a part of the vocal cord vibrates. The tone-giving muscle of the middle register is the thyro-arytenoideus internus, whilst in the falsetto, the cricothyroid is alone in full contraction. The klang tone of the falsetto results from the thyro-arytenoid being relaxed, and the closure of the resulting elliptical slit is effected by the cricothyroid. The cricothyroid is supplied by a special nerve, and hence often remains functionally active when the other glottidean muscles are paretic. The pressure of the air within the trachea during the production of voice is considerable. Cagniard de Latour observed in a man with a tracheal fistula, that the pressure indicated by a manometer when the patient called out at the top of his voice, was equal to a column of water 38 inches in height; when he spoke at his usual pitch, to one of 5 inches; and when he sang a high note, to one of about 8 inches. The deepest notes the human Larynx is capable of producing have about 80 double vibrations in the second, the highest about 992; the former occurring in bass, the latter in soprano voices. Donders‡ gives the limits at 44 vibrations, corresponding to the F of the lowest bass voice, and 1408 for the highest note corresponding to the highest f''' of the soprano, which includes 5 octaves.

660. The various muscular actions which are employed in the production and regulation of the Voice are called forth by an impulse which has been shown (§ 496) to be really *automatic* in its operation, and to be completely under the influence of guiding sensations, although usually originating in a Volitional determination, or giving expression to Emotions or simply to Ideas. This, however, has been proved to be also true of *all* Volitional movements; so that the production of vocal tones constitutes no real exception. It may be safely affirmed that the simple utterance of sounds is in itself an Instinctive act; although the combination of these, whether into music or into articulate language, is a matter of acquirement, which is much more readily made by some individuals than by others. No definite tone can be produced by a Voluntary effort, unless that tone be present to the consciousness during an interval—however momentary—either as immediately produced by an act of Sensation, recalled by an act of Conception, or anticipated by an effort of the Imagination. When thus present, the Will can enable the muscles to

* An entirely different theory of the falsetto has been given, however, by MM. Pétrequin and Diday ("Gazette Médicale," 1844), who consider that the falsetto notes are not produced by the vibration of the vocal cords, but are really 'flute-notes,' formed by the vibrations of the column of air to which the rima glottidis then serves as the embouchure. This view harmonizes well with some of the phenomena of the falsetto voice; but it is open to the objections already stated in regard to the flute theory generally. It may be added that some have attempted to show that the falsetto depends upon a peculiar action on the parts *above* the larynx; but for this doctrine there is no foundation whatever.

‡ Dr. Moore's Translation in Humphry and Turner's "Journ. of Anat. and Physiology," vol. i. 1867, p. 173.

assume the condition requisite to produce it; but under no other circumstances does this happen, except through the particular mode of discipline by which the congenitally deaf may be trained to speak. Such persons are debarred from learning the use of Voice in the ordinary manner; for the necessary guidance cannot be afforded, either through sensations of the present or conceptions of the past, and the imagination is entirely destitute of power to suggest that which has been in no shape experienced. But they may be taught to acquire an imperfect speech, by causing them to imitate particular muscular movements, which they may be made to see; being guided in the imitation of those movements, in the first place by watching their own performance of them in a looking-glass, and afterwards by attending to the muscular sensations which accompany them. Many instances, indeed, are on record, in which persons entirely deaf were enabled to carry on a conversation in the regular way; judging of what was said by the movements of the lips and tongue, which they had learned to connect with particular syllables; and regulating their own voices in reply, by their voluntary power, guided in its exercise by their muscular sensations.*

2. *Of Articulate Sounds.*

661. The Larynx, as now described, is capable of producing those *tones* of which Voice fundamentally consists, and the sequence of which becomes Music: but *Speech* consists in the modification of the laryngeal tones, by other organs intervening between the Glottis and the Os externum, so as to produce those *articulate sounds* of which language is formed. It cannot be questioned that Music has its language; and that it is susceptible of expressing Emotional states of the mind (among those, at least, who have been accustomed to associate these with its varied modes) to even a higher degree than articulate speech. But it is incapable of addressing the Intellect, by conveying definite ideas of objects, properties, actions, &c., in any other way than by a kind of imitation, which may be compared to the signs used in hieroglyphic writing. These ideas it is the peculiar province of Articulate Language to convey; and we find that the vocal organ is adapted to form a large number of simple sounds, which may be readily combined into groups, forming words. The number of combinations which can be thus produced is so inexhaustible, that every language has its own peculiar series; no difficulty being found in forming new ones to express new ideas. There is considerable diversity in different languages, even with regard to the use of the simplest of these combinations; some of them are more easy of formation than others, and these accordingly enter into the composition of all languages; whilst of the more difficult ones, some are employed in one language, some in another —no one language possessing them all. Without entering into any detailed account of the mechanism required to produce each of these simple sounds, a few general considerations will be offered in regard to the classification of them; and the peculiar defect of articulation termed *Stammering* will be briefly treated of.

662. Vocal sounds are divided into Vowels and Consonants; and the distinctive characters of these are usually considered to be, that the Vowels are produced by the Voice alone, whilst the sound of the Consonant is formed by some kind of interruption to the voice, so that they cannot be properly expressed unless conjoined with a vowel. The distinction may be more correctly laid down, however, in this manner:—the Vowel sounds are continuous

* See Dr. Johnstone "On Sensation," p. 128.

tones, modified by the form of the aperture through which they pass out; whilst in sounding Consonants the breath suffers a more or less complete interruption in its passage through parts anterior to the larynx. Hence the really simple Vowel sounds are capable of prolongation during any time that the breath can sustain them; this is not the case, however, with the real Diphthongal sounds (of which it will presently appear that the English *i* is one); whilst it is true of some Consonants. It seems to have been forgotten by many of those who have written upon this subject, that the laryngeal voice is not essential to the formation of either vowels or consonants; for all may be sounded in a whisper. It is very evident, therefore, that the larynx is not primarily concerned in their production; and this has been fully established by the following experiment. A flexible tube was introduced by M. Delau through the nostril into the pharynx, and air was impelled through it into the fauces; then, closing the larynx, he threw the fauces into the different positions requisite for producing articulate sounds, when the air impelled through the tube became an audible whisper. The experiment was repeated, with this variation, that the laryngeal sounds were allowed to pass into the fauces; and each articulated letter was then heard double, in a proper voice, and in a whisper. Observations* made by Professor Moore upon those who from some cause are unable to transmit the air which has passed through the trachea and aperture of the glottis into the mouth, have demonstrated (1) that the larynx is the seat of vocalization for the vowels *a* in all its forms, *i* long, *o* long, and the pure aspirate; also for the short vowels which are to some extent explosive, as *i* in sit, *o* in not, and *e* in err, though the last can also be made in the front part of the mouth. With the exception of the pure breathing and the short vowels, all these sounds receive a finish in the pharynx, nose, and mouth. (2) That the vowels *e* long and *oo*, the diphthong *eu*, which is made up of these two elements, and all the consonants, are made above the larynx.

663. That the Vowels are produced by simple modifications in the form of the external passages, is easily proved both by observation and by imitative experiment. When the mouth is opened wide, the tongue depressed, and the velum palati elevated, so as to give the freest possible exit to the voice, the vowel *a* in its broadest form (as in *ah*) is sounded.† On the other hand, if the oral aperture be contracted, the tongue being still depressed, the sound *oo* (the Continental *u*) is produced. If attention be paid to the state of the buccal cavity, during the pronunciation of the different vowel-sounds, it will be found to undergo a great variety of modifications, arising from varieties of position of the tongue, the cheeks, the lips, and velum palati. The position of the tongue is, indeed, one of the primary conditions of the variation of the sound; for it may be easily ascertained that, by peculiar inflections of this organ, a great diversity of vowel-sounds may be produced, the other parts remaining the same. Still there is a certain position of all the parts which is most favourable to the formation of each of these sounds; but this could not be expressed without a lengthened description. The following table, slightly altered from that of Kempelen, expresses the relative dimensions of the buccal *cavity* and of the *orifice* for some of the principal of these; the number 5 expressing the largest size, and the others in like proportion :—

* See the interesting paper of Prof. E. M. Moore, "New York Medical Record," vol. vii. 1872, p. 49.

† This sound of the vowel *a* is scarcely used in our language, though very common in most of the Continental tongues; the nearest approach to it in English is the *a* in far; but this is a very perceptible modification, tending towards *au*.

Vowel.	*Sound.*	*Size of oral opening.*	*Size of buccal cavity.*
a . . .	as in *ah*	5	5
a . . .	as in *name*	4	2
e . . .	as in *theme*	3	1
o . . .	as in *cold*	2	4
oo . . .	as in *cool*	1	5

These are the sounds of the five vowels, *a*, *e*, *i*, *o*, *u*, in most Continental languages; and it cannot but be admitted that the arrangement is a much more natural one than that of our own vowel series. The English *a* has three distinct sounds capable of prolongation;*—the true broad *a* of *ah*, slightly modified in *far;* the *a* of *fate*, corresponding to the *e* of French; and the *a* of *fall*, which should be really represented by *au*. This last is a simple sound, though commonly reckoned as a diphthong. In Kempelen's scale, the oral orifice required to produce it would be about 3, and the scale of the buccal cavity 4.† On the other hand, the sound of the English *i* cannot, like that of a true vowel, be prolonged *ad libitum;* it is in fact a sort of diphthong, resulting from the transition from a peculiar indefinite murmur to the sound of *e*, which takes its place when we attempt to continue it. The sound *oy* or *oi*, as in *oil*, is a good example of the true diphthong; being produced by the transition from *au* to *e*. In the same manner the diphthong *ou*, which is the same with *ow* in owl, is produced in the rapid transition from the broad *a* of *ah*, to the *oo* of cool.—Much discussion has taken place as to the true character of *y*, when it commences a word, as in yet, yawl, &c., some having maintained that it is a consonant (for the very unsatisfactory reason that we are in the habit of employing *a* rather than *an*, when we desire to prefix the indefinite article to such words), whilst others regard it as a peculiar vowel. A slight attention to the position of the vocal organs during its pronunciation, makes it very clear that its sound in such words really corresponds with that of the long (English) *e;* the pronunciation of the word yawl being the same as that of ēaul, when the first sound is not prolonged, but rapidly transformed into the second. The sound of the letter *w*, moreover, is really of the vowel character, being formed in the rapid transition from *oo* to the succeeding vowel; thus *wall* might be spelt *o͞oal*. Many similar difficulties might be removed, and the conformity between spoken and written language might be greatly increased (so as to render far more easy the acquirement of the former from the latter), by due attention to the state of the vocal organs in the production of the simple sounds.

664. It is not very difficult to produce a tolerably good artificial imitation of the Vowel-sounds. The method adopted by Helmholtz of combining the fundamental note with various harmonics for each vowel has been already referred to (§ 599). By Kempelen it was accomplished by means of an India-rubber ball, with an orifice at each end, of which the lower one was attached to a reed: by modifying the form of the ball, the different vowels could be sounded during the action of the reed. He also employed a short funnel-like tube, and obtained the different sounds by covering its wide opening to a greater or less extent. This last experiment has been repeated by

* The *short* vowel sounds, as *a* in fat, *e* in met, *o* in pot, &c., are not capable of prolongation.

† The mode of making a determination of this kind may here be given for the sake of example. If the broad *a* be sounded, the mouth and fauces being opened wide, and we contract the oral orifice by degrees, at the same time slightly elevating the point of the tongue, we gradually come to the sound of *au;* by still further contracting the orifice, and again depressing the tongue, we form *oo*. On the other hand, in sounding *e*, the tongue is raised nearly to the roof of the mouth; if it be depressed, without the position of the lips being altered, *au* is given.

Mr. Willis; who has also found that the vowel-sounds might be imitated by drawing-out a long straight tube from the reed. In this experiment he arrived at a curious result:—with a tube of a certain length, the series of vowels, *i*, *e*, *a*, *o*, *u*, was obtained by gradually drawing it out; but if the length was increased to a certain point, a further gradual increase would produce the same sequence in an inverted order, *u*, *o*, *a*, *e*, *i*; a still further increase would produce a return to the first scale, and so on. When the pitch of the reed was high, and the pipe short, it was found that the vowels *o* and *u* could not be distinctly formed—the proper tone being injured by the elongation of the pipe necessary to produce them; and this, Mr. Willis remarks, is exactly the case in the Human voice, most singers being unable to pronounce *u* and *o* upon their highest notes. That the function of the glottis is essentially that of giving the pitch and timbre of the vocal sounds, was well shown by a case brought before the Medical Society of London by Dr. Foulis, January 14, 1878. The patient had suffered from disease which had necessitated removal of the larynx, the portion excised extending from the root of the epiglottis to the second ring of the trachea; a large hole remained, through which a tube in two parts, resembling an ordinary tracheotomy tube, was passed upwards and downwards, the lower segment containing a vibrating reed, not unlike an accordion stop, the free extremity being directed downwards. On the insertion of the reed and closure of the throat orifice, the patient read, in an intoning but perfectly intelligible and strong voice, part of the Liturgy, the consonantal variations being as clear as in speech with the healthy organs.

665. The most natural primary division of the Consonants, is into those which require a total stoppage of the breath at the moment previous to their being pronounced, and which, therefore, cannot be prolonged; and those in pronouncing which the interruption is partial, and which can, like the vowel-sounds, be prolonged *ad libitum*. The former have received the designation of *explosive;* and the latter of *continuous*.—In pronouncing the *explosive* consonants, the posterior nares are completely closed, so that the exit of air through the nose is altogether prevented; and the current may be checked in the mouth in three ways — by the approximation of the lips—by the approximation of the point of the tongue to the front of the palate—and by the approximation of the middle of the tongue to the arch of the palate. In the first of these modes we pronounce the letters *b* and *p;* in the second *d* and *t;* in the third, the hard *g* and *k*. The difference between *b*, *d*, and *g*, on the one hand, and *p*, *t*, and *k*,* on the other, seems to depend on this:—that in the former group the approximating surfaces are larger, and the breath is sent through them more strongly at the moment of opening than in the latter. The *continuous* consonants may be again subdivided, according to the degree of freedom with which the air is allowed to make its exit, and the compression which it consequently experiences.—1. The first class includes those in which no passage of air takes place through the nose, and in which the parts of the mouth that produce the sound are nearly approximated together, so that the compression is considerable. This is the case with *v* and *f*, which are produced by approximating the upper incisors to the lower lip, and which stand in nearly the same relation to each other as that which exists between *d* and *t*, or *b* and *p*. The sibilant sounds, *z* and *s*, also stand in a similar relation to each other, they are produced by the passage of air between the point of the tongue and the front of the palate, the teeth being at the same time nearly closed. The simple sound *sh* is formed

* For the sake of proper comparison, this letter should be sounded not as *kay* but *key*.

by narrowing the channel between the dorsum of the tongue and the palate; the former being elevated towards the latter through a considerable part of its length. If, in sounding *s*, we raise the point of the tongue a very little, so as to touch the palate, the sound of *t* is evolved; and in the same manner *d* is produced from *z*. This class also includes the *th;* which, being a perfectly simple sound, ought to be expressed by a single letter, as in Greek, instead of by two, whose combination does not really produce anything like it. For producing this sound, the point of the tongue is applied to the back of the incisors, or to the front of the palate, as in sounding *t*;* but whilst there is complete contact of the tip, the air is allowed to pass out around it.—II. In the second class of continuous consonants, including the letters *m*, *n*, *l*, and *r*, the nostrils are not closed; and the air thus undergoes very little compression, even though the passage of air through the oral cavity is almost or completely checked. In pronouncing *m* and *n*, the breath passes through the nose alone: and the difference of the sound of these two letters must be due to the variation in the form of the cavity of the mouth, which acts by resonance. The letter *m* is a labial, like *b;* but in the former the nasal passage is open, the mouth remaining closed, whilst in the latter the nose is entirely closed, and the sound is formed at the moment of opening the mouth; hence the passage from *m* to *b* is made with great facility. The same correspondence exists between *n* and *t*, or *n* and *g* (the particular part of the tongue approximated to the palate not being of much consequence in the pronunciation of *n*); and hence it is that the transition from *n* to *t*, or from *n* to *g*, is so easy, that the combinations *nt* and *ng* are found abundantly in most languages. The sound of *l* is produced by bringing the tip of the tongue into contact with the palate, and allowing the air to escape around it, at the same time that a vocal tone is generated in the larynx; it differs therefore from *th* in the position at which the obstruction is interposed, as well as in the slight degree of compression of the air which it involves. The sound of the letter *r* depends on the absolute vibration of the point of the tongue, in a narrow current of air forced between the tongue itself and the palate.†—III. The sounds of the third class are scarcely to be termed consonants, since they are merely *aspirations* caused by an increased force of breath. These are *h*, and the gutteral *ch*‡ of most foreign languages (the Greek χ). The first is a simple aspiration; the second an aspiration modified by the elevation of the tongue, causing a slight obstruction to the passage of air, and an increased resonance in the back of the mouth. The sound would become either *g* or *k*, if the tongue, whilst it is being produced, were carried-up to touch the palate.§

666. These distinctions come to be of much importance when we apply ourselves to the treatment of defects of articulation. Great as is the number of muscles employed in the production of definite vocal sounds, the number is much greater for those of articulate language; and the varieties of combination which we are continually forming unconsciously to ourselves, would not be suspected without a minute analysis of the separate actions. Thus, when we utter the explosive sounds, we check the passage of air through the

* Hence it is easy to understand the substitution of *t* or *d*, for the English *th*, by foreigners.

† Donders describes no less than four modes in which the letter *r* can be made. 1, by the lips; 2, by the tongue; 3, by the uvula; and 4, by some part between this and the chordæ vocales. The *r*, as ordinarily but distinctly pronounced, is produced by about thirty vibrations of the tongue in the second. The uvular *r* by from nineteen to twenty-eight.

‡ The English *ch* is merely a combination of *t* with *sh;* thus *chime* might be spelt *tshime*.

§ The general classification proposed by Dr. Marshall Hall has been here adopted, with some modification as to the details.

posterior nares in the very act of articulating the letter; and yet this important movement commonly passes unobserved.—We must regard the power of forming the several articulate sounds which have been adverted to, and their simple combinations, as so far resulting from intuition, that it can in general be more readily acquired by early practice than other actions of the same complexity: but we find that among different Races of Men, there exist tendencies to the production of different sounds, which, though doubtless influenced in great degree by early habit (since we find that children, when first learning to speak, form their habits of vocalization in great degree in accordance with the examples amidst which they are placed), are certainly also dependent in part upon congenital constitution; as we often see in the case of children among ourselves, who grow up with certain peculiarities of pronunciation, not thus derived from imitation, of which they do not seem able to divest themselves.

667. It is in want of power to *combine* the different muscular actions concerned in vocalization, that the defect termed *Stammering* essentially consists. Many theories regarding the nature of this impediment have been proposed; and there can be little doubt that it may be attributed to a great variety of exciting causes. A disordered action of the nervous centres must, however, be regarded as the proximate cause; though this may be (to use the language of Dr. M. Hall) either of *centric* or of *excentric* origin—that is, it may result from a morbid condition of the ganglionic centre, or from an abnormal impression conveyed through its afferent nerves. When of centric origin (and this is probably the most general case), the phenomena of Stammering and Chorea have a close analogy to each other; in fact, stammering is frequently one of the modes in which the disordered condition of the nervous system in Chorea manifests itself.—It is in the pronunciation of the Consonants of the *explosive* class that the stammerer experiences the greatest difficulty. The total interruption to the breath which they occasion, frequently becomes quite spasmodic;* and the whole frame is thrown into the most distressing semi-convulsive movement, until relieved by expiration. In the pronunciation of the *continuous* Consonants of the first class, the stammerer usually prolongs them by a spasmodic continuance of the same action; and there is, in consequence, an impeded, but not a suspended respiration. The same is the case with the *l* and *r* in the second class. In pronouncing the *m* and *n*, on the other hand, as well as the aspirates and vowels, it is sometimes observed that the stammerer prolongs the sound by a full and exhausting expiration. In all these cases, then, it seems as if the muscular sense resulting from each particular combination of actions, became the stimulus to the involuntary prolongation of that state. It is possible that the defect may result, in some instances, from malformation of the parts about the fauces, producing an abnormal stimulus of this kind in some particular positions of the organ; and such cases *may be* really benefited by an operation for the removal of these parts. But the effect of such an operation is certainly exerted in most cases through the *mind* of the patient; the expectation of benefit from it tending to improve his command over the muscles of vocalization, which Emotional excitement always impairs; and the improvement is usually proportional to the confidence which he has been led to feel in the result. The slightest disturbance of the feelings is sufficient in most stammerers to induce a complete perturbation of the vocal powers; the very fear that

* By Dr. Arnott this interruption is represented as taking place in the larynx; that such is not usually the case, the Author believes that a little attention to the ordinary phenomena of voice will satisfactorily prove.

stammering will occur, particularly under circumstances which render it peculiarly annoying, is often sufficient to bring it on in a predisposed subject; and the tendency to consensual imitation sometimes occasions stammering in individuals (especially children) who never show the slightest tendency to it except when they witness the difficulty in others.

668. The method proposed by Dr. Arnott for the prevention of Stammering, consists in the connection of all the words by a vocal intonation, in such a manner that there shall never be an entire stoppage of the breath. It is justly remarked by Müller, however, that although this plan may afford some benefit, it cannot do everything; since the main impediment occurs in the middle of words themselves. One important remedial means, on which too much stress cannot be laid, is to study carefully the mechanism of the articulation of the difficult letters, and to practise their pronunciation repeatedly, slowly, and analytically. The patient would at first do well to practise sentences from which the explosive consonants are omitted; his chief difficulty arising from the spasmodic suspension of the expiratory movement being thus avoided. Having mastered these, he may pass on to others, in which the difficult letters are sparingly introduced; and may finally accustom himself to the use of ordinary language. One of the chief points to be aimed at, is to make the patient feel that he *has* command over his muscles of articulation; and this is best done, by gradually leading him from that which he finds he *can* do, to that which he fears he *cannot*. The fact that stammering people are able to *sing* their words better than to *speak* them, has been usually explained on the supposition that, in singing, the glottis is kept open, so that there is less liability to spasmodic action; if, however, as here maintained, the spasmodic action is not in the larynx, but in the velum palati and the muscles of articulation, the difference must be due to the direction of the attention rather to the muscles of the larynx than to those of the mouth.—One of the most important objects to be aimed at in the treatment of stammering, consists in the prevention of all Emotional disturbance in connection with the act of Speech; and this requires the exercise of the Voluntary power over the direction of the thoughts, in the following modes:—1. To *reduce* mental emotion, by a daily, and even hourly, habit of abstracting the mind from the subject of stammering, both while speaking and at other times. 2. To *avoid exciting* mental emotion by attempting unnecessarily to read or speak, when the individual is conscious that he shall not be able to perform these actions without great distress. 3. To *elude* mental emotion, by taking advantage of any little artifice to escape from stammering, so long as the artifice continues to be a successful one.—Much may frequently be done, also, by constitutional treatment, adapted to improve the general vigour of the nervous system.*

CHAPTER XVII.

OF THE INFLUENCE OF THE NERVOUS SYSTEM ON THE ORGANIC FUNCTIONS.

669. Of the modes in which the Nervous System influences the Organic Functions, a great number have been already considered; for it has been shown to be concerned in providing the mechanical conditions, either immediate or

* See on the subject of "Stammering and its Treatment," a useful pamphlet under this title, by Bacc. Med. Oxon, 1850; and Mr. Bishop's treatise "On Articulate Sounds, and on the Causes and Cure of Impediments of Speech."

remote, under which alone these functions can be performed; so that, when its activity ceases, they cannot be much longer maintained. But the influence of the Nervous System is not alone exerted upon the motor or contractile tissues of the body; for there is good evidence that it has a direct operation upon the molecular changes which constitute the functions of Nutrition, Secretion, &c.; and this view may be admitted to its fullest extent, without our being thereby led to regard the processes in question as *dependent* upon Nervous agency—a doctrine for which there seems no valid foundation. Throughout the animal body, it may be observed that, the more Vegetative the nature of any function, the less is it under the influence of the Nervous System, save where that influence is required to bring it into harmony with functions, sometimes by exciting, sometimes by checking, and sometimes by otherwise modifying them, very much in the way that a rider guides and controls the movements of his horse.—It is evident that this influence must be principally exerted through the *Sympathetic* or *Visceral* system of nerves, since a large proportion of the organs on which it operates are supplied by no other: and hence this apparatus has been commonly designated the 'Nervous system of *organic* life' as distinguishing it from the Cerebro-spinal system, which is the 'Nervous system of *animal* life.' There is, however, no such parallelism betweem them as this designation would imply; for whilst the operations of the Cerebro-spinal system *essentially constitute* the Animal life of the individual, those of the Sympathetic cannot be fairly said to do more than *control* and *direct* those of Nutrition and Secretion.—Nor, on the other hand, is such a view justifiable on histological grounds since the whole of the Invertebrata possess only non-medullated fibres, whilst in the Vertebrata, the fibres of Remak, and the medullated fibres are found commingled both in the mixed nerves supplying the skin and muscles, and in the sympathetic fibres that are distributed to the viscera, though, undoubtedly, a considerable difference exists in the relative proportion of the fibres. We shall now inquire into the structure and relations of the Sympathetic System; and shall then examine the nature of the actions which there seems reason to attribute to it.

670. *Sympathetic Nervous System.*—That collection of scattered but mutually-connected ganglia and nerves, of which this apparatus is made up, may be ranged under the following groups:—1. The isolated ganglia and nerves in immediate connection with the Viscera, which seem to be the chief centres of the system; these form three principal plexuses, the *Cardiac*, the *Solar*, and the *Hypogastric*. 2. The double chain of *Prevertebral* ganglia, with connecting cords, which lies in front of the Vertebral column, and which communicates on the one hand with the Spinal nerves, and on the other with the before-named plexuses. Under this head we should probably rank the minute Cranial ganglia, which are situated in the neighbourhood of the Organs of Sense, and in immediate connection with the branches of the Fifth pair that proceed to them; these are the *ophthalmic*, *otic*, *spheno-palatine*, and *submaxillary* ganglia. 3. The *ganglia on the posterior roots* of the Spinal nerves; under which head we are probably to rank not only the *Gasserian* ganglion of the Fifth pair, but also the ganglia near the roots of the Pneumogastric and Glosso-pharyngeal nerves.—The trunks of the Sympathetic are made up of different orders of fibres; some of these having their central termination in the vesicular matter of the Sympathetic ganglia themselves, whilst others are derived from the Cerebro-spinal system. The former, which are all of the 'gelatinous' kind,* are

* It must be carefully borne in mind, that, although the proper Sympathetic fibres are all 'gelatinous,' yet that the Cerebro-Spinal system contains 'gelatinous' fibres of its own, which are very abundant in some parts. An account of Küttner's and Remak's views on

most abundant in the great Visceral plexuses; but they may be traced from the prevertebral ganglia into the Spinal nerves, part of them proceeding to the ganglia on their posterior roots (whence fibres are given-off that mingle with their spinal fibres), whilst other parts enter the anterior roots and mingle with *their* fibres. On the other hand, the latter, which are of the 'medullated' kind, are derived by the same cords of communication (these being commonly termed the 'roots' of the Sympathetic, but being really commissural bands that bring the two systems into connection) from both roots of the Spinal nerves, and pass through the prevertebral ganglia into the Sympathetic system, without undergoing any ostensible change. Thus it appears that the Cerebro-spinal and Sympathetic systems *interpenetrate* one another; each having its own series of ganglionic centres, and of trunks connected with them; but each system transmitting its fibres into the trunks of the other, so as to be peripherally distributed with their ramifications. Giannuzzi* has made a special study of the rami communicantes of the great sympathetic cord in Mammals by the Wallerian method—that is, by dividing particular roots of the spinal cord, and after the lapse of a certain period examining the rami communicantes microscopically with the object of determining whether any, and if any, what amount of degeneration of the nerve fibres had taken place. The results of his observations are that, with the exception of a few fibres, the fibres of the rami communicantes are entirely derived from the spinal cord, or at least have their nutritive centres in the posterior spinal ganglia, and in the spinal cord. The few exceptional fibres are characterized by their great delicacy and the want of double contours, and pass from the sympathetic ganglia through the rami to the roots of the spinal cord. They may be entirely absent. The number of motor fibres sent by the spinal cord to the Sympathetic is greater than the number of sensory fibres. Giannuzzi has also ascertained that the trophic influence of the spinal cord extends along the nerves derived from the spinal cord after they have traversed a sympathetic ganglion. Arndt† describes the ganglia of the Sympathetic as composed of an apparently homogeneous matrix, through which granules giving off from 2 to 4 fine processes, are distributed. According to Frantzel,‡ the cells of the sympathetic and of the spinal ganglia are invested by a capsule of connective tissue formed by an expansion of the neurilemma of the nerves, which is lined by a layer of pavement epithelium. Beale, Arnold, and others describe a single straight fibre emerging from the nucleus of each sympathetic cell (Figs. 193, 194), and a spiral fibre that appears to be in connection with the surface of the cell, and which, after winding for a few turns round the straight fibre, pursues an opposite direction; such cells must be regarded as bipolar. There is some doubt whether the cells of the spinal ganglia present this structure or not; Schwalbe§ and Courvoisier‖ having only been able to discover one fibre originating from each cell; the cells of these ganglia are therefore unipolar.

671. The connections and distribution of the principal trunks and branches of the Sympathetic system may be concisely stated as follows:—In the cervical portion of the sympathetic, the presence of the following nerve-fibres appears to have been satisfactorily demonstrated.¶ 1. Vaso-motor nerves for the

the structural relations of the prevertebral ganglia, will be found in the "Medico-Chirurgical Review," 1868.

¶ See Hermann, "Grundriss der Physiologie," 1867, p. 424.

corresponding half of the head, that probably arise from a centre situated in the medulla oblongata, which governs the tone not only of these vessels, but of the entire vascular system throughout the body. This ganglionic centre is constantly in action. Its influence can be abolished by section of the spinal cord in the cervical region, and may be reflectorially depressed, as Cyon and Ludwig have shown, by irritation of the depressor nerve, which is a centripetal branch of the vagus (§ 238). A local depression of its influence may be also reflectorially induced by irritation of the sensory nerve supplying any part* whilst its action may be excited through the agency of carbonic acid. 2. Fibres distributed to the dilatator pupillæ, that probably arise from the oculo-pupillary or cilio-spinal centre, seated in the medulla oblongata—a centre that, like the preceding, is in a constant state of activity, and is influenced in a manner similar to the respiratory and vaso-motor centres; hence in dyspnœa the pupil dilates, and the vessels distributed to the eye contract. 3. Secretory fibres for the salivary glands, irritation of which contracts the vessels and modifies the characters of the secretion, whilst section is followed by dilatation of the vessels. 4. Fibres possessing an accelerating, and others exerting a depressing influence on the heart. The former, according to MM. E. and M. Cyon, emerge by the third branch of the inferior cervical ganglion; whilst the first and second branches constitute the roots of the depressor nerve. 5. Fibres passing to the central cerebro-spinal organs, which reflectorially stimulate the nerves retarding the action of the heart. As regards the thoracic portion of the sympathetic trunk, Otto Nasse† and Bernard only obtained negative results from its division or excitation. The superior thoracic ganglion gives accelerator fibres to the heart. The plexus cardiacus, arising from the thoracic sympathetic, also receives branches from the vagus and the depressor nerves. The splanchnic nerves, which arise from the lower six thoracic ganglia, contain fibres exerting an inhibitory, and others exerting an exciting influence‡ over the movements of the intestine; secretory fibres acting on the kidneys (Bernard); vaso-motor nerves influencing the calibre of the whole abdominal system of vessels;§ and lastly, centripetal fibres exerting reflectorially an inhibitory influence on the action of the heart. The abdominal portion gives off numerous branches which aid in forming the cœliac, mesenteric, renal, suprarenal, spermatic, and hypogastric plexuses, and these, when irritated, occasion movements in the parts to which they are distributed, as the intestine (small and large), bladder, ureters, uterus, vesiculæ seminales, spleen, &c., partly by their direct action on the muscular fibres, partly by modifying the supply of blood to them.‖ Of the *ophthalmic* ganglion (§ 447), the branches are distributed, not merely to the iris, whose radiating fibres are made to contract through their instrumentality, as already explained (§ 567); but also to the vascular apparatus of the eyeball, and especially to the ciliary processes, which seem to possess a sort of erectile character. The *otic* ganglion, which communicates with the third division of the Fifth pair and with the Glosso-pharyngeal, may be considered, from the distribution of most of its branches to the tensor tympani and circumflexus palati muscles, as ministering to the exercise of the sense of Hearing, in somewhat the same mode that the ophthalmic ganglion seems to do to that of vision (§§ 447, 604). The

§ v. Bezold, Untersuch. passim. Cyon, and Ludwig, "Arbeiten," &c. 1867.

‖ See Nasse, loc. cit.

spheno-palatine ganglion (Fig. 258), whose connections are with the Fifth and the Facial nerves, seems in like manner to minister, by the distribution of its branches on the mucous membrane of the nasal cavity and the palate, to the senses of Smell and Taste. It has been shown by Prévost* to be purely sensory in its function. Of the *submaxillary* ganglion, which also is chiefly connected with the Fifth and the Facial nerves, the branches proceed almost entirely to the Submaxillary gland, and according to Pflüger† and Palladino,‡ terminate in the gland cells. 6. The fibres which arise from the ganglia on the posterior roots of the Spinal nerves (if really belonging to the Sympathetic system) must be distributed along with the branches proceeding from the trunks which they help to form; as must also a part of those fibres which are sent from the proper Sympathetic ganglia into the roots of the same nerves, a large part of them, however, being distributed upon the blood-vessels of the Spinal Cord itself.

672. If, then, it be inquired what inferences we are entitled to draw respecting the functions of the Sympathetic system of nerves, from our knowledge of its Anatomical distribution, we are at once justified in replying that the muscular tissue which directly enters into the formation of the vessels, and especially of the smaller arteries, is supplied essentially from this source. In accordance with this, it is found that excitation of the sympathetic nervous ganglia, whether by direct or reflex irritation, leads to contraction of the vessels, and consequent diminution in the activity of all organic processes, such as secretion, nutrition, growth, and development; their paralysis, as is well seen in cases of section of the cervical sympathetic, disclosing itself by the establishment of the opposite conditions. Again, it is certain that a large proportion of the Muscular apparatus which directly ministers to the Organic functions—that, namely, which surrounds the alimentary canal from the stomach downwards, with the gland-ducts which open into it, and that, also, which forms the walls of the bladder and uterus, of the ureters and Fallopian tubes—*receives no other nervous supply;* and, consequently, that of whatever motor influence these parts may receive from Mental states or from excitation not applied to themselves, this system of nerves must be the channel. The same may be said, too, in regard to that greater portion of the Glandular apparatus, which is exclusively supplied by the Sympathetic nerve, and chiefly by the plexuses that embrace its blood-vessels; since any such alterations in its rate of activity, or in the character of its products, as depend upon conditions of Mind, can be brought about through no other instrumentality.—It is not a little remarkable, however, that those portions of the Muscular apparatus of Organic life, which most obviously exhibit in their action the influence of the Nervous system, both in their respondence to emotional states and in their 'sympathy' with disturbance in other functions—namely, the Heart and the Stomach—derive a considerable part of their nervous supply directly from the Cerebro-spinal system. And it is still more significant that most of those glands whose function is occasional, and whose states of activity are most obviously influenced by affections of the Mind, are specially supplied by Cerebro-spinal nerves, in addition to the Sympathetic plexuses which they receive on the walls of their blood-vessels: thus, the Lachrymal and Salivary glands are supplied with branches of the Fifth and Facial nerves; and the Mammary glands by branches of the Intercostals. It cannot but be deemed highly probable, then, from this circumstance alone, that the influence of mental states upon the function of

* Brown-Séquard's "Archives de Physiologie," tom. i. p. 207.
† Loc. cit. ‡ Abstract in "Centralblatt," 1873, p. 782.

Secretion may be exerted through the nerves of the Cerebro-spinal system, as well as through those of the Sympathetic.

673. It must be in virtue of the connections of the Sympathetic with the Cerebro-spinal system, that the parts which are solely supplied with nerves from the former, are capable of transmitting sensory impressions to the Sensorium. It is true that, under ordinary circumstances, these parts are insensible; that is, impressions made upon them do not travel onwards through the Spinal Cord to the Encephalon: but their sensibility is acutely manifested in morbid states, in which the impressions seem to be propagated further than usual, in virtue of their greater potency. That it is the office of the ganglia on the roots of the Spinal nerves to "cut off sensation," that is, to prevent the further transmission of sensory impressions, is an old doctrine; and there seems much reason to believe that this may be effected by the free communication between one ganglion cell and another, which is established through the vesicular substance of a ganglion, so that the whole force of ordinary impressions on the nerve-fibres is lost by diffusion among the rest of their contents. The same principle seems to apply to the motor fibres; for there are cases which show that when fibres obviously belonging to Cerebro-spinal nerves pass through Sympathetic ganglia, they do not so rapidly or so surely transmit motor impulses, as when they have no such relation to ganglia.*

674. The effects of section and of galvanization of the cut extremities of the sympathetic nerve in the neck have been carefully investigated by Bernard, Waller, Brown-Séquard,† and others. On dividing the nerve, the blood-vessels of that side of the head dilate, and with the freer current of blood which is then established through the capillaries, an increase of the vital properties of all the tissues on the same side of the head is associated. Thus the sensibility of the retina for light appears to be augmented, whence follow contraction of the pupil, retraction of the globe of the eye, partial closure of the eyelid, and projection of the *membrana nictitans* (where present) with increased flow of tears. The temperature and sensibility of the skin, and the cutaneous secretions, are also much increased—the temperature in some of Dr. Waller's experiments‡ rising as much as 18° Fahr., and the skin in some of M. Bernard's being bathed with perspiration. The colour of the venous blood assumes a brighter hue, and its coagulation is more rapid. The muscles respond more readily to weak, and more energetically to strong, stimuli, and retain their irritability longer; rigor mortis consequently sets in more slowly and endures for a longer period; hypertrophy of the facial bones has been noticed by Schiff, and Benedikt§ has observed a similar result to occur in certain muscles; whilst it further appears from Snellen's researches‖ that even the inflammatory and reparative processes, as the effusion of serum, the formation of pus, the absorption of effused blood, and the cicatrization of wounds, take place with very much greater energy than rapidity. On the contrary, when the upper cut extremity of the nerve is galvanized, all these phenomena are reversed: for now, as a consequence of the contraction of the blood-vessels and the diminished supply of blood which ensues, the vital properties of the tissues are diminished, the pupil dilates, the eyelid is widely opened, the temperature and sensibility of the parts decrease, the contractile power of the muscles is less strongly marked, their normal galvanic current is feeble, and cadaveric rigidity sets in quickly and soon passes off, putrefaction

‖ Henle and Meissner's "Bericht," 1857, p. 373.

immediately supervening. The effects produced by section of the Sympathetic in the neck are much more strongly marked when the cervical ganglia are destroyed, and Bernard* states that closely similar results follow section of the Sympathetic nerves distributed to the vessels of the extremities. In these later experiments he found that division of the roots of the spinal nerves within the spinal canal, though abolishing sensation and motion in the limb beyond, yet produced no effect upon its temperature; whilst if after such section the sciatic or brachial nerves were divided, an immediate exaltation of temperature ensued; clearly showing that the nerve-fibres devoted to the conduction of sensory and motor impulses issuing from the spinal cord had been joined by a third set of fibres, either proceeding directly from the sympathetic ganglia, or through and beyond these from some part of the cerebro-spinal system, the office of which is to preside over the contraction of the vessels and calorification. A further corroboration of this view was obtained by experiments in which the lumbar ganglia of the Sympathetic were destroyed, when the vascular changes and the increase of temperature in the lower limb were observed without the occurrence of any paralysis. Dr. Waller† has shown that some of the results of irritation of the cervical portion of the sympathetic may be made apparent during life by pressure of the point of the finger behind the ramus of the jaw, though they are associated with other phenomena proceeding from irritation of the pneumogastric. The more important symptoms observed were dyspnœa, cardiac and gastric disturbance, tingling and heat of the ear, lasting for upwards of half an hour, and in one instance dilatation followed by contraction of the pupil. Dr. Waller‡ has also ingeniously shown the effects of paralysis of the vaso-motor nerves of the arm in the living body, by applying a freezing mixture to the ulnar nerve at the elbow; the effect in the first instance being to produce a fall of temperature equal to about 0·5° C. in the two inner fingers; but as the vaso-motor nerves became paralysed, the temperature gradually rose till it attained a height of from 5° to 6° C. above that of the outer fingers: the difference between the outer and inner fingers appeared to be partially attributable to a decrease in the temperature of the former as well as to an increase in that of the latter, owing to the diversion of part of the blood of the radial into the ulnar artery. The effects of percutaneous excitation of the sympathetics in man by means of electricity are very slight, consisting only, according to MM. Eulenberg and Guttmann,§ of an almost inappreciable dilatation of the pupil, and a lowering of the frequency of the pulse. As the smaller vessels contract, there is probably an increase of pressure in the larger ones, but it must be remembered that it is difficult to irritate the cervical Sympathetic without coincidentally exciting the vagus-depressor nerve of Cyon, the laryngeal nerve, and descendens noni, which may materially influence the result. The vaso-motor nerves of the upper extremity do not proceed from the spinal cord, in common with the sensori-motor nerves forming the brachial plexus, but issue from it at a much lower point—namely, between the third and seventh dorsal nerves. The vaso-motor nerves for the lower extremities spring from the adjoining dorsal roots, and not from those which form the sciatic plexus. The chief vaso-motor of the body which supplies all the vessels distributed to the viscera is the splanchnic nerve, and by reason of the large quantity of blood these vessels can contain the splanchnic nerve plays the principal part in the distribution of the blood

* See "Gazette Hebdomad.," Août, 1862; "Comptes Rendus," vol. ii. 1862; and "Journal de la Physiologie," vol. v.

† "Proceedings of the Royal Society," vol. xi. p. 302. ‡ Ibid. p. 436.

§ "Die Pathologie des Sympatheticus," 1873, p. 202.

generally in the body.* If it be irritated, the blood is driven in large quantity into the vessels of the head and limbs, whilst if it be paralysed the blood accumulates in the viscera, and the head and extremities are rendered anæmic. Budge† maintains that the small arteries throughout the body can be made to contract by electrical irritation of the pedunculus cerebri, which, therefore, he regards as the centre of the vaso-motor nerves, but there can now be no question that the principal vaso-motor centre is, as already stated (§ 238), situated in the medulla oblongata.

675. It is very difficult to give a satisfactory explanation of the *dilatation* observed in the vessels of certain regions of the body when the nerves supplying them are irritated. The most marked instances of such dilatation are seen in the vessels of the submaxillary gland when the chorda tympani, and in those of the penis when the nervi erigentes are stimulated. In the latter case, if the nerves of both sides be cut, erection of the penis on sexual excitement or by mechanical irritation of the sensory fibres in the pudendal nerves is rendered impossible ; yet if the distal extremities of the nerves be irritated, the corpora cavernosa swell, and the copious flow of bright-coloured blood that follows an incision into them, shows that the circulation has been greatly increased in activity. Claude Bernard‡ and Schiff § admit a direct dilating action of the nerves, and this view receives support from the experiments of Mr. Gaskell.‖ Others have suggested that in the case of the penis the phenomena are due to the contraction of the small veins, or to contraction of the trabeculæ of the corpora cavernosa impeding the return of blood ; but against this it has been shown that erection does not follow ligature of the principal veins. M. Legros,¶ again, believes that they are due to an exaggeration of the ordinary peristaltic action of the smaller arteries, but it is not easy to understand how this could act in the absence of valves. It is not improbable that two conditions co-operate in producing the increased flow of blood in the instances adduced above. On the one hand, as is especially seen in the case of the submaxillary gland, irritation of the chorda tympani may augment the attraction of the tissue of the gland for the blood, and thus act in producing a *vis a fronte*, and on the other, as occurs more particularly in the case of the penis, the nervi erigentes exert, when stimulated, an inhibitory influence over the ordinary vaso-motor and constricting nerves exactly comparable to that of the vagi over the movements of the heart. *Reflex* dilatation of vessels has

This observer finds in the case of the mylo-hyoid muscle of the frog in which the changes in diameter of the vessels on stimulation of the nerve supplying the muscle, may readily be followed, that there is a latent period lasting five or six seconds, and not preceded by constriction (so that there was no question of exhaustion). This was followed by dilatation which reached its maximum in from 20 to 30 seconds, and then gradually subsided till the stream became normal. The dilatation was in some instances so great that the diameter of the artery increased to nearly three times the size it possessed before the commencement of the stimulation. Curare, when administered to an animal, affects the dilator fibres alone, and not the constrictor.

been observed by Lovén,* who found that when the central ends of the saphena and great auricular nerves were stimulated in the rabbit dilatation of the saphena artery and of the median vein of the ear respectively occurred, and the effects of stimulation of the branches of the Fifth nerve distributed to the tongue on the vessels of the salivary glands has been already alluded to.

676. It can only be through the Nervous System that the Muscular apparatus of Organic life is acted upon by states of Mind. Although no exertion of the *Will* can produce an effect upon any part of it, yet there are various organs whose muscular walls are influenced on the one hand by Emotional states, and on the other by the state of Expectant Attention. The Heart sympathizes so much with the Emotions, that the language of almost all civilized nations refers to it as the *seat* of the 'feelings'; but we have as yet no certain evidence whether this influence is transmitted through the Sympathetic or through the Pneumogastric nerve. The former seems the more probable channel, when we bear in mind that it can be through the sympathetic alone that those alterations in the diameter of the blood-vessels take place which give rise to the *blush* of modesty or shame, or to the pallor which alternates with this in many states of mental agitation.† So, again, the influence of Emotional states is strikingly manifested in the production of the peculiar turgescence of the Erectile tissues (§ 257); and here we have a striking example of the utter powerlessness of the Will in the well-known fact, that no amount of sexual *desire* will produce erection, if the mind be possessed with any feeling of doubt or apprehension as to the existence of the sexual *ability*. The muscular walls of the alimentary canal seem frequently to be excited to increased action by agitating emotions; but it may be doubted how far this is a primary effect of the mental state, or how far it is consequent upon the influence of that state upon the secretions poured into the Canal.—The influence of the state of *expectant attention*, as of the emotions, is strongly manifested in the case of the Heart; the action of which, as Sir H. Holland has remarked, "is often quickened or otherwise disturbed by the mere centering the consciousness upon it, without any emotion or anxiety. On occasions where its beats are audible, observation will give proof of this, or the physician can very often infer it while feeling the pulse; and where there is liability to irregular pulsation, such action is seemingly brought on, or increased, by the effort of attention, even though no obvious emotion be present."‡ There can be no doubt that the movements of the lower part of the Alimentary Canal are capable of being affected in a similar manner; since we may frequently trace the rapid descent of the fæcal mass into the rectum, when we expect to be shortly able to discharge it; and it is in great part in this mode, that *habit* operates in producing a readiness for defecation at particular times, and that bread-pills and other supposititious purgatives unload the bowels."§

* Ludwig's "Arbeiten," 1866.

† The pallor of extreme fear or terror is probably due rather to a state tending to Syncope, arising from a partial failure of the heart's action.

‡ "Chapters on Mental Physiology," p. 16.

§ The Author may mention the two following cases, which have fallen within his own knowledge, as curious illustrations of the influence of mental states upon the movements of the alimentary canal.—The first of these occurred in the person of a literary man, of a somewhat hypochondriacal temperament, who had been troubled with continued costiveness, for which he had been accustomed to take an aperient pill daily. Finding that this ceased to have its usual effect, and being fearful of increasing his regular dose, he applied for advice to a practitioner, who, having had former experience of what Mental agency alone would do, determined to try its effect in this instance. Seating his patient before him, with the abdomen uncovered, he desired him to fix his attention intently upon his abdominal sensations, and assured him that in a short time he was quite certain that he would begin to feel a movement in his bowels, which would end in a copious evacuation. He himself did nothing but

677. *Trophic Nerves.*—The existence of a special system of nerves possessing a direct influence on the process of nutrition, though suggested by other writers, was first clearly enunciated by Samuel of Leipsic, and has been so warmly supported by Duchenne, that he has declared that "if trophic nerves did not exist, it would be necessary to invent them." The positive facts which have led to their admission are, however, comparatively few, and in fact may almost be considered as limited to the single one, demonstrated by Ludwig, that certain glands can be excited to action by the stimulation of their nerves, independently of their blood supply (§ 107). The view taken by Samuel* is that the so-called trophic nerves arise from the ganglia on the posterior roots of the spinal nerves and run centrifugally to the tissues. When stimulated increased activity of all the nutritive processes is observed, cell-growth in particular taking place with abnormal rapidity. On the contrary, their paralysis, as by section, leads to diminished activity in the nutritive operations, and atrophy. In proof of these statements Samuel adduced the results of many experiments showing that if a rough fragment of bone be passed beneath the sciatic nerve stretching it like a cord and producing continual irritation of its fibres, the thigh, leg, and foot swell in the course of 24 or 36 hours. The whole limb below the seat of irritation of the nerve becomes hyperæsthetic, its temperature rises, and an ill-smelling discharge takes place from the wound, all circumstances indicating the increased activity of the various processes both of nutrition and disintegration. In like manner laryngitis may be produced by irritating the superior laryngeal nerves, and after death the mucous membrane is found swollen and reddened; so by irritation of the Vagi, just below their exit from the skull, the symptoms and pathological conditions characterizing pneumonia may be obtained, and by irritating the spinal cord with a bristle dipped in croton oil passed through it in such a direction as to affect the posterior roots of the spinal nerves at the level of the last dorsal vertebra, he observed great hyperæmia, tumefaction, and elevation of temperature in the lower limbs.† Dr. Axmann found that when the spinal nerves of frogs were divided on the distal side of their prevertebral ganglia, the nutrition of the parts supplied by them was much more injuriously affected than it was when the section was made between the ganglia and the spinal cord. A large number of pathological cases are on record which certainly appear to support the views of Samuel. One of the most typical is that given by Sir James Paget in his lectures on Nutrition, on the authority of Mr. Hilton:—"A man was at Guy's Hospital, several years ago, who, in consequence of fracture of the lower end of the radius, repaired by an excessive quantity of new bone, suffered compression of the median nerve. He had ulceration of the thumb, and of the fore and middle fingers, which had

look steadily at his patient, with an air of great determination and confidence, and point his finger at the abdomen, moving it along the arch of the colon, and (as it were) in the course of the convolutions of the small intestines, so as to aid the patient in fixing his attention upon them. In a short time the expected movements were felt, and a copious evacuation soon followed; and for some time afterwards the bowels continued to act freely without medicine.—In the other case, a Lecturer at a public Institution was seized with a strong impulse to defecate during his lecture; and was greatly inconvenienced by the effort necessary to restrain it. Before every subsequent lecture in the same place, the same impulse returned upon him, notwithstanding that he might have previously unloaded his bowels elsewhere. In this case, there was obviously a state of apprehension combined with the simple anticipation; but the influence of the latter is shown by the fact, that in no other place did this individual experience the impulse in question under the like circumstances.

resisted various treatment, and was cured only by so binding the wrist, that the parts on the palmar aspect being relaxed, the pressure on the nerve was removed. So long as this was done, the ulcers became and remained well; but as soon as the man was allowed to use his hand, the pressure on the nerves was removed, and the ulceration in the parts supplied by it returned."* In the American war a special Hospital having been set aside for injuries and diseases of nerves, the surgeons, Messrs. Mitchell, Morehouse, and Keen, had large opportunities of observing the effects of such lesions. The conditions they found to occur in the parts below the seat of injury were atrophy of muscles, and various subacute inflammatory states indicated by tumefaction and congestion, œdema, thickening of the cuticle and glossiness of the skin, cracks and fissures in it, bed-sores, eczema, curved and talon-like nails, retraction of the skin of the ungual phalanx and exposure of the matrix, painful swelling of joints and altered or arrested secretions (Sweat). Bärensprung again has satisfactorily shown that in some cases of Herpes, at least, the ganglia on the posterior roots of the spinal nerves are inflamed, and Vandyke Carter† has pointed out that in cases of leprosy the cutaneous affection is often limited to certain nerve-regions, which become anæsthetic, whilst post-mortem examination shows that the nerves in question are swollen and affected with hypertrophy of the interstitial connective tissue. Lesions of the spinal cord and hemiplegia of cerebral origin are often rapidly followed by disease of the joints (Charcot), and lesions of certain parts of the encephalon, as the optic thalamus, corpus striatum, and pons, are followed by ecchymosis of the lungs, pleura, and stomach. Looking at the facts obtained from clinical observation, Hermann thinks it is legitimate to conclude, not that the existence of trophic nerves is satisfactorily established, but that the central grey matter of the nerve centre, the nerve fibre, and the peripheric terminal organ, represent not only a functionally active body, but a trophic or nutritive unity; so that in the case of muscle or gland, the nerve centre, nerve, and muscular and glandular tissues form one whole, in which various changes take place, the last expression of which is in the muscle contraction and in the gland secretion, and the central and peripheral extremities of the nerve mutually reacting on one another. The arguments for and against the existence of *trophic nerves* are numerous and of nearly equal weight, so that it is difficult in the present state of knowledge to make a positive statement in regard to them. As Hermann,‡ who has stated these arguments most clearly, remarks, much of the evidence in favour of their existence has been drawn from clinical observations and not from physiological researches, though the former method of inquiry has many disadvantages. The first observations that led to the suggestion of the presence of a distinct set of trophic nerves were those of Magendie, who showed that, after intra-cranial section of the fifth pair of nerves of one side, the eye of the same side was apt to become inflamed; the cornea first became cloudy, then losing its epithelium, and the deeper tissues being successively invaded, till suppuration of the globe followed by atrophy occurred. These changes were regarded as the effects of the division of trophic nerves. Disturbances in the nutrition of the mucous membrane of the lips, after intra-cranial division of the fifth nerve, were also noticed by

* Similar cases are given by M. Gillette in the "Dictionnaire Encyclopédique," by M. Charcot in Brown-Séquard's "Archives de Physiologie," and Mr. I'Anson, "Lancet," 1871, vol. ii. p. 913; by Hutchinson in the "London Hospital Reports" for 1866; by Schiefferdecker and Edis, a storehouse of such facts in the work of Messrs. Mitchell, Morehouse, and Keen, "On Gunshot Wounds and other Injuries of Nerves."

‡ "Handbuch der Physiologie," Band i. 1879.

Bernard and others. Division of both vagi in the neck is followed by serious disturbance of the functions of the lungs and other organs, which ultimately occasion death. Section of the sciatic nerve leads, in many instances, to ulceration of the foot. Schiff,* again, has shown that after section of all the nerves proceeding to an extremity, the limb diminished in size, the periosteum became thickened and lamellated, and the inorganic constituents of the bones appeared to have diminished. Similarly, Obolensky,† after practising division of the nerves in the cord supplying the testes, found that on the side of the lesion the testes in the course of four months became atrophied, and the contents of the tubulus had undergone fatty degeneration. After section of the vas deferens alone, without injury of the nerves, the testes long preserved their normal characters. The effects of division of the nerves supplying the submaxillary gland in the dog‡ are diminution in the volume, weight, and consistence of the gland, and a change in its colour from yellow to reddish-grey. Extirpation of the upper cervical ganglion in young cocks§ is followed by atrophy of the comb. Division of the cervical sympathetic in rabbits is said to cause increase in the growth of the ears and more rapid growth of the hair on the injured side; whilst division of the nerves of both sides is followed by diminution in the volume of the brain, after eighteen months, as compared with a similar and uninjured animal.‖ Section of motor nerves leads to atrophy, and even disappearance of the proper muscular tissue, proliferation of the nuclei, and development of connective tissue. On the other hand, it must be acknowledged that many of the phenomena above noticed, and which have been held to demonstrate the existence of trophic nerves, admit of another explanation. Thus, in the case of the lesions of the eye and of the mucous membrane of the mouth, occurring after division of the Fifth nerve, there is strong reason for believing that they are due to the loss of sensibility of the parts, which permits foreign and irritating substances to remain long in contact with the parts first affected, and precludes the performance of those protective movements which, under ordinary circumstances, are employed to prevent mischief. The entry of particles of dust into the eye, and the lodgment of particles of food between the cheeks and teeth, constitute sources of irritation that are commonly removed by winking, rubbing the eyes with the fingers or in animals with the fore-foot, a flood of tears, or by the movements of the tongue; but if allowed to remain, inflammation, proceeding to ulceration, soon occurs; and the best evidence that this is really the cause of the damaged eye is the fact, that if the eye be protected with a watch-glass, the inflammatory symptoms do not supervene, or, if they have already commenced, rapidly disappear. Again, many of the phenomena regarded as due to lesion of nerves, such as hypertrophy or atrophy of various organs, may with equal probability be referred to the influence of the divided nerves on the vessels, causing increased or diminished blood supply to the part. Where both sides are placed under precisely similar conditions little alteration is noticeable. Thus, Joseph¶ found that if the nerves of one extremity were divided, and both were then embedded in plaster of Paris, no changes enabling

him to determine which was the injured side were perceptible. Brown-Séquard and others have in like manner found very few and slight trophic changes after division of one cervical sympathetic. Then, again, there are the remarkable phenomena observed and described by Snellen, Schiff, and many others,* which follow intra-cranial section of the fifth pair of nerves, and which consist in the occurrence of conjunctivitis within a few hours of the operation, the discharge of a thick, puriform mucus, haziness, ulceration, and ultimately sloughing of the cornea, and the loss of the eye on the same side as that on which the nerve has been divided. Lastly, there are the atrophic changes which occur in muscles when a motor nerve is divided, and which have been described with great minuteness by M. Vulpian,† by Erb, and others, the fibres losing their transverse striæ, and gradually undergoing fatty degeneration, whilst the nuclei of the sarcolemma and the interstitial connective tissue undergo hypertrophy. Thus it would at first sight appear there is a large amount of evidence proving the direct influence of the nervous system on the processes of nutrition.

678. It is not less certain, however, that weighty evidence can be adduced to show that the nervous system is not required for the due performance of the nutritive processes, and has little or no direct action upon them, the pathological phenomena above mentioned as concurrent with their persistent irritation, or consequent on their paralysis, resulting from changes in the supply of blood, which again are caused by the action of the vaso-motor nerves upon the vessels. In proof of this it may be observed, in the first place, that nutrition and the processes which minister to it, as absorption, assimilation, circulation, secretion, the fixation of new material, and the disintegration and removal of the old, are all actively performed by plants, though there is no evidence of the existence of such a rudimentary nervous system in the vegetable kingdom. Again, in many of the lower forms of animal life, as well as in the more lowly organized tissues of the higher animals, such as cartilage, fat, and connective tissue, few or no nerves are present, and nervous influence, if perceptible at all upon the process of nutrition in them, must therefore be indirect. Thirdly, daily experience shows that even in the higher animals, sensory nerves may be divided without any failure in the processes of nutrition of the parts they supplied.‡ In regard to *motor* nerves, the experiments of Reid made long ago showed clearly that although atrophy of muscle follows section if the limb be allowed to remain quiescent, yet that the muscles retain all their characters if they are methodically exercised by passive movement, or by the action of the electrical current. Brown-Séquard records cases where *mixed* nerves§ have been divided without apparent alteration being produced either in the temperature or in the nutrition of the parts beyond. Lastly, even with regard to the sympathetic there is evidence that section of its trunk on one side in the neck, if anything, improves rather than deteriorates nutrition on the same side of the head, for the vaso-motor system being paralysed, the current of blood becomes freer, causing the hair on that side to grow more rapidly in the mammal, and the lateral half of the comb of the cock to hypertrophy, whilst injuries heal more rapidly and the tissues, as in the case of the cornea especially, are more tolerant of irritation and injury ; and such cases as those recorded by Dr. Carnochan and Dr. Conner‖ where Meckel's

ganglion was extirpated, and no apparent mischief followed, show that some other conditions than the mere abolition of the function of the sympathetic ganglia must be present in order that impairment of nutrition may take place.

679. It is to be observed, moreover, that whilst some of the phenomena above alluded to are explicable on the supposition that the blood-supply is interfered with, possibly by persistent contraction of the blood-vessels, in others there may have been some interference with the lymphatic system, the relations of which to the nerves is at present unknown, whilst others again admit of a different explanation. Take, for example, the case of the eye after division of the fifth nerve. The experiments of Büttner and Meissner,* v. Bezold,† v. Hippel, and others have shown that if the eye be carefully covered and protected from external lesion, no pathological lesions occur after the section, whilst if it be exposed ulceration soon sets in. Here it is probable that the loss of sensibility of the cornea leads to dryness, and the entrance of foreign bodies, in consequence of the ordinary act of winking being neglected, and such dryness is a predisposing cause to inflammation. In a case under the care of the Editor, in which the fifth nerve was paralyzed on both sides, one eye was wholly lost, but in the other incomplete ptosis occurred, and the inflammation was long limited to the part of the cornea exposed in the half-shut condition. In this part a deep ulcer formed, whilst the rest of the cornea was perfectly bright and transparent, and the iris was not implicated till a very late period. In like manner Brown-Séquard has shown that many of the effects which may be observed to follow injuries of the nerves of the extremities, may be referred to a want of power on the part of the animal, both to perceive and to withdraw them from irritating and depressing conditions (cold, wet, and pressure). It must be remembered also that many of Mitchell's cases were severe gunshot wounds, and that the blood-vessels and other tissues besides the nerves were always implicated.‡

680. The influence of particular conditions of the Mind, in exciting suspending, or modifying various Secretions, is a matter of daily experience. The *Lachrymal* secretion, for example, which is continually being formed to a small extent for the purpose of bathing the surface of the eye, is poured out in great abundance under the moderate excitement of the emotions, either of joy, tenderness, or grief. It is checked, however, by violent emotions; hence, in intense grief, the tears do not flow; and it is a well-known indication of moderated sorrow when the gush takes place, this very act affording a further relief. The flow of *Saliva*, again, is stimulated by the sight, the smell, the taste, or even by the *thought* of food, especially of such as is of a savoury character. On the other hand, violent emotion may suspend the salivary secretion; as is shown by the well-known test, often resorted to in India, for the discovery of a thief amongst the servants of a family,—that of compelling all the parties to hold a certain quantity of rice in the mouth during a few minutes,—the offender being generally distinguished by the comparative dryness of his mouthful at the end of the experiment. There is much reason to believe that the secretion of *Gastric* fluid is effected, in the same manner as that of the saliva, by the impressions made by food upon the senses; for it has been ascertained by Bidder and Schmidt§ that it is copiously effused into the stomachs of dogs that

Wiss.," 1873, p. 708; Joseph, Reichert's "Archiv," 1872, No. 2; Fischer, "Journ. of Anat. and Physiology," vol. vi. p. 222; Vulpian, "Comptes Rendus," 1872, t. lxx. No. 15. § Op. cit. p. 35.

have been kept fasting, when flesh or any other attractive food is placed before them. That the secretion, on the other hand, is entirely suspended by powerful mental emotion, seems almost certain, from the well-known influence which this has in dissipating the appetite for food, and in suspending the digestive process when in active operation. As a cheerful state of feeling, on the other hand, seems to be decidedly favourable to the performance of the digestive function, it probably exerts a beneficial influence, as to both quantity and quality, on the secretion of gastric fluid. Of the influence of mental states on other secretions concerned in the reduction and appropriation of the food (such as the Biliary, Pancreatic, and intestinal fluids), neither observation nor experiment has as yet afforded any satisfactory information. It is a prevalent, and perhaps not an ill-founded opinion, that melancholy and jealousy have a tendency to increase the quantity, and to vitiate the quality, of the *Biliary* fluid. Perhaps the disorder of the organic functions is more commonly the source of the former emotion than its consequence; but it is certain that the indulgence of these feelings produces a decidedly morbific effect by disordering the digestive processes, and thus reacts upon the nervous system by impairing its healthy nutrition. A copious secretion of *fœtid gas* not unfrequently takes place in the intestinal canal, under the influence of any disturbing emotion; or the usual *fluid secretions* from its walls are similarly disordered. The tendency to Defecation which is commonly excited under such circumstances is not, therefore, due simply to the relaxation of the sphincter ani (as commonly supposed); but it is partly dependent on the unusually stimulating character of the fæces themselves. The same may be said of the tendency to Micturition, which is experienced under similar conditions; the change in the character of the *urine* becoming perceptible enough among many animals, in which it acquires a powerfully disagreeable odour under the influence of fear, and thus answers the purpose which is effected in others by a peculiar secretion. The *halitus from the Lungs* is sometimes almost instantaneously affected by bad news, so as to produce fœtid breath. The *odoriferous secretion of the Skin*, which is much more powerful in some individuals than others, is increased under the influence of certain mental emotions (as fear or bashfulness), and commonly also by sexual desire. It appears from the observations of Vulpian, Luchsinger (§ 377), and others to be excreted under the influence of two antagonistic nerve centres, one of which excites, whilst the other inhibits it. The excito-secretory nerves arise in the region of the medulla oblongata, and descending issue from the lumbar region of the Cord, and run in the sciatic nerve. The inhibitory nerves arise also from the medulla oblongata, but enter the sympathetic system of nerves. The *Sexual* secretions themselves are strongly influenced by the condition of the mind. When it is frequently and strongly directed towards objects of passion, these secretions are increased in amount, to a degree which may cause them to be a very injurious drain on the powers of the system. On the other hand, the active employment of the mental and bodily powers on other objects, has a tendency to render less active, or even to check altogether, the processes by which they are elaborated.*

* This is a simple physiological fact, but of high Moral application. The Author would say to those of his younger readers, who urge the wants of Nature as an excuse for the illicit gratification of the sexual passion, "Try the effects of *close mental application* to some of those ennobling pursuits to which your profession introduces you, in combination with *vigorous bodily exercise* (for the effects of which see § 555), before you assert that the appetite is unrestrainable, and act upon that assertion." Nothing tends so much to increase the desire as the continual direction of the mind towards the objects of its gratification, especially under the favouring influence of sedentary habits; whilst nothing so effectually represses it as the

681. No Secretion so strongly manifests the influence of the Nervous system, and especially of Emotional states, both upon its quantity and its quality, as that of the *Mammary* glands. Although the production of Milk, when once established, continually goes on in the breasts of a nursing female, yet it is obviously accelerated in the first instance, and augmented afterwards, by the mechanical irritation of the nipple produced by the suction of the infant; and this alone (or in combination with the strong *desire* to furnish milk) has been effectual in producing the secretion in girls and old women, and even in men. Again, in the nursing female the secretion is often suddenly augmented by the *sight* of the infant, or even by the *thought* of him in absence, especially when associated with the idea of suckling; this gives rise to the sudden rush of blood to the gland, which is known by nurses as the *draught*, and which may probably be attributed to a dilatation of the Mammary arteries, through the instrumentality of their Sympathetic nerves, analogous to that which takes place in the act of blushing (§ 676).—Although we are continually witnessing indications of the powerful influence of Emotional states upon the qualities of the Mammary secretion, yet it is probable that such influence is not at all peculiar to the milk; and that we only recognize it more readily in this case, because the digestive system of the infant is a more delicate apparatus for testing it than any which the Chemist can devise; affording proof, by disorder of its function, of changes in the character of the secretion which no examination of its physical properties could detect. The following remarks on this subject are abridged from Sir A. Cooper's valuable work on the Breast:—"The secretion of milk proceeds best in a *tranquil state of mind*, and with a cheerful temper; then the milk is regularly abundant, and agrees well with the child. On the contrary, a *fretful temper* lessens the quantity of milk, makes it thin and serous, and causes it to disturb the child's bowels, producing intestinal fever and much griping. *Fits of anger* produce a very irritating milk, followed by griping in the infant, with green stools. *Grief* has a great influence on lactation, and consequently upon the child. The loss of a near and dear relation, or a change of fortune, will often so much diminish the secretion of milk, as to render adventitious aid necessary for the support of the child. *Anxiety of mind* diminishes the quantity, and alters the quality, of the milk. The reception of a letter which leaves the mind in anxious suspense lessens the draught, and the breast becomes empty. If the child be ill, and the mother is anxious respecting it, she complains to her medical attendant that she has little milk, and that her infant is griped and has frequent green and frothy motions. *Fear* has a powerful influence on the secretion of milk. I am informed by a medical man who practises much among the poor, that the apprehension of the brutal conduct of a drunken husband will put a stop for a time to the secretion of milk. When this happens, the breast feels knotted and hard, flaccid from the absence of milk, and that which is secreted is highly irritating; whilst some time elapses before a healthy secretion returns. *Terror*, which is sudden and great fear, instantly stops this secretion."

determinate exercise of the mental faculties upon other objects, and the expenditure of nervous energy in other channels.—There seems to be something in the process of training young men for the Medical Profession, which encourages in them a laxity of thought and expression on these matters, that too frequently ends in a laxity of principle and of action. It might have been expected that those who are so continually witnessing the melancholy consequences of the violation of the Divine Law in this particular, would be the last to break it themselves; but this is unfortunately very far from being the case. The Author regrets being obliged further to remark, that some works which have issued from the Medical press contain much that is calculated to excite, rather than to repress, the propensity; and that the advice sometimes given by practitioners to their patients is immoral as well as unscientific.

Of this two striking instances, in which the secretion, although previously abundant, was completely arrested by this emotion, are detailed by Sir A. Cooper. "Those passions which are generally sources of pleasure, and which, when moderately indulged, are conducive to health, will, when carried to excess, alter, and even entirely check, the secretion of milk."

682. There is even evidence that the Mammary secretion may acquire an actually *poisonous* character, under the influence of violent mental excitement; for certain phenomena which might otherwise be regarded in no other light than as simple coincidences, appear to justify this inference, when interpreted by the less striking but equally decisive facts already mentioned. "A carpenter fell into a quarrel with a soldier billeted in his house, and was set upon by the latter with his drawn sword. The wife of the carpenter at first trembled from fear and terror, and then suddenly threw herself furiously between the combatants, wrested the sword from the soldier's hand, broke it in pieces, and threw it away. During the tumult, some neighbours came in and separated the men. While in this state of strong excitement, the mother took up her child from the cradle, where it lay playing, and in the most perfect health, never having had a moment's illness; she gave it the breast, and in so doing sealed its fate. In a few minutes the infant left off sucking, became restless, panted, and sank dead upon its mother's bosom. The physician who was instantly called in found the child lying in the cradle, as if asleep, and with its features undisturbed; but all his resources were fruitless. It was irrecoverably gone."* In this interesting case, the milk must have undergone a change which gave it a powerful sedative action upon the susceptible nervous system of the infant.—The following, which occurred within the Author's own knowledge, is perhaps equally valuable to the Physiologist, as an example of the similarly fatal influence of undue emotion of a different character; and both should serve as a salutary warning to mothers, not to indulge either in the exciting or in the depressing passions. A lady having several children, of which none had manifested any particular tendency to cerebral disease, and of which the youngest was a healthy infant a few months old, heard of the death (from acute hydrocephalus) of the infant child of a friend residing at a distance, with whom she had been on terms of close intimacy, and whose family had increased almost contemporaneously with her own. The circumstance naturally made a strong impression on her mind; and she dwelt upon it the more, perhaps, as she happened, at that period, to be separated from the rest of her family, and to be much alone with her babe. One morning, shortly after having nursed it, she laid the infant in its cradle, asleep and apparently in perfect health; her attention was shortly attracted to it by a noise; and on going to the cradle, she found her infant in a convulsion, which lasted a few moments and then left it dead. Now, although the influence of the mental emotion is less unequivocally displayed in this case than in the last, it can scarcely be a matter of doubt; since it is

* Dr. Von Ammon, in his treatise "Die ersten Mutterpflichten und die erste Kindespflege," quoted in Dr. A. Combe's excellent little work on "The Management of Infancy."—Similar facts are recorded by other writers. Mr. Wardrop mentions ("Lancet," No. 516), that having removed a small tumour from behind the ear of a mother, all went well until she fell into a violent passion; and the child, being suckled soon afterwards, died in convulsions. He was sent for hastily to see another child in convulsions, after taking the breast of a nurse who had just been severely reprimanded; and he was informed by Sir Richard Croft that he had seen many similar instances. Three others are recorded by Burdach ("Physiologie," § 522); in one of them, the infant was seized with convulsions on the right side and hemiplegia on the left, on sucking immediately after its mother had met with some distressing occurrence. Another case was that of a puppy, which was seized with epileptic convulsions on sucking its mother after a fit of rage.

natural that no feeling should be stronger in the mother's mind under such circumstances, than the fear that her own beloved child should be taken from her, as that of her friend had been; and it is probable that she had been particularly dwelling on it, at the time of nursing the infant on that morning. —Another instance, in which the maternal influence was less certain, but in which it was not improbably the immediate cause of the fatal termination, occurred in a family nearly related to the Author's. The mother had lost several children in early infancy from a convulsive disorder; one infant, however, survived the usually fatal period; but whilst nursing him one morning, she had been strongly dwelling on the fear of losing him also, although he appeared a very healthy child. In a few minutes after the infant had been transferred into the arms of the nurse, and whilst she was urging her mistress to take a more cheerful view, directing her attention to his thriving appearance, he was seized with a convulsion-fit, and died almost instantly. Now although there was here unquestionably a predisposing cause, of which there is no evidence in the other cases, it can scarcely be doubted that the *exciting* cause of the fatal disorder is to be referred to the mother's anxiety. This case offers a valuable suggestion,—which, indeed, would be afforded by other considerations, that an infant under such circumstances should not be nursed by its mother, but by another woman of placid temperament, who has reared healthy children of her own.

683. There is abundant evidence that a *sudden* and *violent* excitement of some depressing Emotion, especially Terror, may produce a severe and even a fatal disturbance of the Organic functions; with general symptoms (as Guislain* has remarked) so strongly resembling those of sedative Poisoning, as to make it highly probable that the *blood* is *directly* affected by the Emotional state, through nervous agency; and in fact, the emotional alteration of various secretions, just alluded to (§§ 680–682), seems much more probably attributable to some affection of the blood, than to a primary disturbance of the secreting process itself. Although there can be no doubt that the *habitual* state of the Emotional sensibility has an important influence upon the general activity and perfection of the Nutritive processes—as is shown by the well-nourished appearance usually exhibited by those who are free from mental anxiety as well as from bodily ailment, contrasted with the "lean and hungry look" of those who are a prey to continual disquietude—yet it is not often that we have the opportunity of observing the production of change in the nutrition of any specific part, by strong emotional excitement. In the two following cases, the correspondence of the effects to their alleged causes *may* have been only casual; and a much larger collection of facts would be needed to *establish* the rationale here advanced as probable. But so many analogous though less strongly-marked phenomena are presented in the records of medical experience, and the influence of the Emotions upon the products of Secretion is so confirmatory, that there does not seem any reasonable ground for hesitation, in admitting that the same explanation may apply here also. The first of these cases, cited by Guislain (loc. cit.) from Ridard, is that of a woman who, after seeing her daughter violently beaten, was seized with great terror, and suddenly became affected with gangrenous erysipelas of the right breast. But a still more remarkable example of local disorder of nutrition, occasioned by powerful emotion, and determined as to its seat by the intense direction of the attention to a particular part of the body, is narrated by Mr. Carter.† "A lady who was watching her little child at play, saw a heavy window-sash fall

* "Leçons Orales sur les Phrénopathies," tom. iii. pp. 165–168.

† "On the Pathology and Treatment of Hysteria," p. 24.

upon its hand, cutting off three of the fingers; and she was so much overcome by fright and distress as to be unable to render it any assistance. A surgeon was speedily obtained, who, having dressed the wounds, turned himself to the mother, whom he found seated, moaning, and complaining of pain in her hand. On examination, three fingers, corresponding to those injured in the child, were discovered to be swollen and inflamed, although they had ailed nothing prior to the accident. In four-and-twenty hours incisions were made into them, and pus was evacuated; sloughs were afterwards discharged, and the wounds ultimately healed."

684. The influence of the state of *expectant attention*, in modifying the processes of Nutrition and Secretion, is not less remarkable than we have already seen it to be in the production or modification of Muscular movements (§ 676). It seems certain that the simple *direction of the consciousness* to a part, independently of emotional excitement, but with the *expectation* that some change will take place in its organic activity, is often sufficient to induce such an alteration; and would probably always do so, if the concentration of the attention were sufficient. The most satisfactory exemplification of this principle has been given by the experiments of Mr. Braid, who has succeeded in producing very decided changes in the secretions of particular organs, by the fixation of the attention upon them in the 'hypnotic' state* (§ 540). Thus he brought back an abundant flow of milk to the breast of a female who was leaving off nursing from defect of milk, and repeated the operation upon the other breast a few days subsequently, after which the supply was abundant for nine months; and in another instance he induced the catamenial flow on several successive occasions, when the usual time of its appearance had passed. It is not requisite, however, to produce the state of Somnambulism for this purpose, if the attention can be sufficiently drawn to the subject in any other mode; thus Mr. Braid† has repeatedly produced the last-named result on a female who possessed considerable power of mental concentration, by inducing her to fix her thoughts upon it for ten or fifteen minutes, so as to bring on a state of Abstraction.—Now the effects which are producible by this *voluntary* or determinate direction of the consciousness to the result, are doubtless no less producible by that *involuntary* fixation of the attention upon it, which is consequent upon the eager expectation of benefit from some curative method in which implicit confidence is placed. It is to such a state that we may fairly attribute most, if not all, the cures, which have been worked through what is popularly termed the 'imagination.' The cures are real facts, however they may be explained; and there is scarcely a malady in which amendment has not been produced, not merely in the estimation of the patient, but in the more trustworthy opinion of medical observers, by practices which can have had no other effect than to *direct the attention* of the sufferer to the part, and to keep alive his *confident expectation* of the cure. The 'charming-away' of warts by spells of the most vulgar kind, the imposition of royal hands for the cure of the 'evil,' the pawings and strokings of Valentine Greatrakes, the manipulations practised with the 'metallic tractors,'‡ the invocations of

* 'On the subject of Hypnotism,' see "Brit. Med. Journ." vol. ii., p. 381, 1880, and "The Nineteenth Century," Sept., 1880.

† See his important Memoir on 'Hypnotic Therapeutics,' in "Edinb. Monthly Journal," July, 1853.—Of the reality of this last result, the Author has had an opportunity, through Mr. Braid's kindness, of personally satisfying himself.

‡ Dr. Haygarth, of Bath (in conjunction with Mr. Richard Smith, of Bristol), tested the value of 'Perkin's metallic tractors' by substituting two pieces of wood painted in imitation of them, or even a pair of tenpenny nails disguised with sealing-wax, or a couple of slate-pencils; which they found to possess all the virtues that were claimed for the real instruments.

Prince Hohenlohe, *et hoc genus omne*—not omitting the globulistic administrations of the Infinitesimal doctors, and the manipulations of the Mesmerists, of our own times,—have all worked to the same end, and have all been alike successful. It is unquestionable that, in all such cases, the benefit derived is in direct proportion to the *faith* of the sufferer in the means employed; and thus we see that a couple of bread-pills will produce copious purgation, and a dose of *red* poppy syrup will serve as a powerful narcotic if the patient have entertained a sufficiently-confident expectation of such results.*

685. This state of confident expectation, however, may operate for evil, no less than for good. A fixed belief that a mortal disease had seized upon the frame, or that a particular operation or system of treatment would prove unsuccessful, has been in numerous instances (there is no reason to doubt) the direct cause of a fatal result. Thus M. Ridard relates the case of a man, thirty years of age, who was affected with stone in the bladder, and who saw a patient die by his side, after being operated upon for the same complaint. The man's imagination became excited; his thoughts were constantly fixed upon the operation which he himself expected to undergo, and upon the probable death that would follow; and in fact, without any operation at all, he died at the end of a month, affected with gangrene both of the penis and scrotum. Hence also, it is that the morbid feelings of the Hypochondriac, who is constantly directing his attention to his own fancied ailments, tend to induce real disorder in the action of the organs which are supposed to be affected.—In the same category, too, may be placed those instances (to which alone any value is to be attached), wherein a *strong and persistent impression* upon the mind of a Mother, has appeared to produce a corresponding effect upon the development of the *fœtus in utero*. In this case, the effect (if admitted to be really exerted) must be produced upon the maternal *blood*, and transmitted through it to the fœtus; since there is no nervous communication between the parent and the offspring. There is no difficulty, however, in understanding how this may occur, after what has been already stated (§ 203 *et seqq.*) of the influence of minute alterations in the Blood in determining local alterations of nutrition.

CHAPTER XVIII.

OF GENERATION.

1. *General Character of the Function.*

686. HAVING now passed in review the various operations which are concerned in maintaining the life of the *individual*, we have next to proceed to those whose are destined to the perpetuation of the *race* by the production of successive generations of similar beings. The question of the occurrence of spontaneous generation is one that has received great attention during the last few years, but the opinions that have been expressed both for and against it are still *sub judice*. No doubt can be entertained that under all ordinary circumstances fluids containing organic substances in solution or suspension when exposed to temperatures of 40° and 100° or 110° F., and more rapidly as the mean temperatures of 70° and 80° are approximated, exhibit evidences of life. The fluid—such, for instance, as an infusion of turnip, carrot, meat,

* A remarkable and thoroughly well-attested case of the cure of a fistula lachrymalis, which had advanced so far as to involve disease of the bones of the nose, is recorded in the "History of the Portroyalists."

cheese—becomes cloudy, from the formation or separation of an infinite number of minute molecules, almost unresolvable by the highest microscopic powers. Soon Bacteria, or small rod-shaped bodies appear, which exhibit movements of a slow oscillating character, then more swiftly-moving monads and vibrios, and, finally, infusoria of various forms and more complex structure. Two views have been advanced to explain the development of these lowly-organized beings. On the one hand, the *panspermists* maintain that the air is crowded with spores so small as to be imperceptible to the highest microscopic powers, and which, falling on suitable soil, as into moist solutions of organic substances, immediately begin to increase and multiply ; and they point to the fact that the purer the air, whether it be that obtained on high mountain-tops, or which has been filtered through cotton wool, or has been made to pass through red-hot tubes, the less likely is the solution, if protected by closing the mouth of the vessel in which it is contained, to become the seat and focus of life. On the other hand, the *heterogenists* contend that, as on the Darwinian theory pushed to its furthest limit, the whole animal and vegetable kingdoms may be derived from some simple form, which must have originated from the action of light and heat, or of heat alone, on the inorganic materials of which the earth is composed, it is not unlikely that the same process is constantly being repeated when the appropriate conditions are present ; and they point as additional arguments in favour of their view, to the circumstances that, whatever may be the care taken in filtering the air admitted to organic infusion, and even when a boiling temperature has been maintained for several minutes with hermetic closure of the vessel during the process of ebullition, it is, in many cases, impossible to prevent the development of Bacteria, though the absence or great diminution of air, or rather of oxygen, thus occasioned prevents them forming in any considerable numbers. They refer also to the extraordinary numbers in which the Bacteria appear—numbers which they believe to be incompatible with their production from the spores supposed by the panspermists to be floating in the air ; and, lastly, they refer to various experiments which seem to show that the lowest forms of life may be germinated in solutions consisting exclusively of inorganic compounds. When it is considered how difficult it is to preserve the air admitted to the solution used in these experiments in a perfect state of purity, and our ignorance of the amount of heat which the spores of the lower organisms can bear exposure to without destruction, it would seem at present that it is safest to hold the doctrine of panspermism, though it must be admitted to present several points of considerable difficulty.*

687. Among Plants, and the lower tribes of Animals, a multiplication of independent beings takes place without any sexual process whatever, by a process of *gemmation* or 'budding' from the parent-stock ; these 'buds,' at first entirely nourished by it, gradually become less and less dependent upon it, and at last detach themselves and maintain a separate existence. Now this process may be regarded as essentially the same with that of the multiplication of cells by *subdivision*, which is one of the most ordinary operations of growth and development; and it is peculiar in nothing else than this,—that the newly-formed structure, instead of remaining as a constituent and dependent part of the parental fabric, is capable of living independently of it, and of thus existing as a distinct individual when spontaneously or artificially detached. Among the higher tribes of Animals, as in Man, this mode of

* The student will find a very full discussion, with an historical résumé of this subject, in Dr. Bastian's "Beginnings of Life," 1872 ; Burdon Sanderson, "Nature," vol. viii. p. 478 ; Heuzinger, Samuelson, Putzeys, and Gscheidlen, in Pflüger's "Archiv," for 1873 and 1874.

reproduction, which is merely a multiplication of the individual, and not a real Generative process, does not present itself, at least in the adult state; for in no instance do we find that a part of the body separated from the rest can develop the organs which are necessary for the sustenance of its existence; and the power which the organism possesses, of regenerating parts which it has lost by disease or accident, is restrained within very narrow limits (§ 333). But there is good ground to believe, that such a multiplication by subdivision *may* take place at that earliest period of embryonic life, at which the germ is nothing else than a mass of cells, wherein no distinction of parts has as yet manifested itself; and that the production of two complete individuals, held together only by a connecting band, may arise from some cause which determines the subdivision of the germinal mass, at the period when its grade of development corresponds with that of the Hydra or Planaria. And this view of the case is confirmed by the facts already stated (§ 333) in regard to the higher degree of the regenerating power during embryonic life, infancy, and childhood, as compared with that which remains after the development of the fabric has been completed.

688. The proper act of Generation in Man, as in the Animal and Vegetable Kingdoms generally (see PRINC. OF COMP. PHYS., Chap. XI.), uniformly involves the union of the contents of two peculiar cells, which may be designated as the 'sperm-cell' and the 'germ-cell.' In all the higher Animals, the 'sperm-cell' develops a self-moving *spermatozoon*, whilst the 'germ-cell' (germinal vesicle), whose contents are fertilized by the spermatozoon, is embedded in a mass of *yolk* destined for the early nutrition of the embryo thence originating: so that this embryo, when supplied with the requisite warmth, as well as drawing into itself the aliment stored-up for it, gradually evolves itself into the likeness of its parent. There is a great difference, however, among the different tribes of Animals, as to the degree of assistance thus afforded to the embryo,* the general rule being, that the higher the form which the embryo is ultimately to attain, the longer is it supported by its parent. Hence we find the embryos of most Invertebrate animals coming-forth from the egg in a condition very unlike their perfect type, and only acquiring this after a long succession of subsequent alterations, which frequently involve a complete change of form, or *metamorphosis*. In Fishes, however, the embryo, though far from having completed its embryonic development at the time of its emergence from the egg, does not differ so widely from the adult type. In Birds, there is a provision for a much more advanced development; the store of nutritious matter, or 'yolk,' being so large as to allow the whole series of changes requisite for the formation of the complete chick to take place before it leaves the egg. In the Mammalia, on the contrary, the quantity of yolk contained in the ovum is very small, but the embryo is only dependent upon it for the materials of its increase during the earliest stages of its evolution; for it speedily forms a special connection with the parent structure, by means of which it is enabled to receive a continual supply of newly-prepared aliment, so as to be supported at the expense of this until far advanced in its development. Some approaches to this arrangement are met with among certain of the lower animals, but it is only in the higher Mammalia that it is completely carried out; and it is only in this class, too, that we find a supplemental provision for the nutrition of the offspring after it has come forth into the world.† In many of the lower tribes of animals,

* For an account of these varieties, see "The Life Histories of Animals, including Man," by A. S. Packard, New York, 1876; and "Comparative Embryology," by F. M. Balfour, F.R.S. Macmillan, 1880.

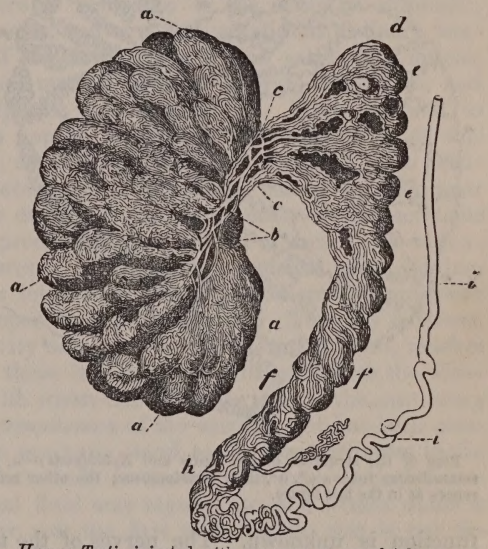
† For different types of segmentation, *vide infrd.*

the fertilization of the ova is accomplished without any sexual congress; the spermatic fluid effused by the male coming into direct contact with the ova previously deposited by the female; but in all the higher tribes, as in Man, the spermatic fluid is conveyed into the oviducts of the female, so as to impregnate the ovum shortly after it has quitted the ovarium, or even before its final escape from it.

2. *Action of the Male.*

689. The Spermatic fluid of the Male is secreted by glandular organs known as *Testes*. Each of these consists of several lobules, which are separated from each other by processes of the Tunica Albuginea that pass down between them, and also by an extremely delicate membrane (described by Sir A. Cooper under the name of Tunica Vasculosa) consisting of minute ramifications of the spermatic blood-vessels united by areolar tissue. Each lobule (Fig. 308, *a a*) is composed of a mass of convoluted *tubuli seminiferi*, throughout which blood-vessels are minutely distributed. The lobules differ greatly in size, some containing one, and others many of the tubuli; the total number of the lobules is estimated at about 450 in each testis, and that of the tubuli at 840. The walls of the tubuli are firmer than those of similar gland-canals elsewhere; for the basement-membrane on which the epithelium rests, consists of a tolerably firm but extensible envelope, composed of a hyaline elastic membrane with oval flattened nuclei. They are lined by several layers of epithelial cells—the seminal cells.* These cells may be divided into outer cells, situated next to the membrana propria, and inner cells, nearer to the lumen. The inner cells are generally arranged in more than two layers; they are polyhedral, possess a transparent spherical nucleus, and are separated from each other by a clear interstitial matrix, the *germ reticulum*. The cells present evidences of undergoing rapid multiplication, and exhibit amœboid movements. The convolutions of the tubuli are so arranged that each lobule forms a sort of cone, the apex of which is directed towards the *rete testis* (*b*); and when they have reached to within a line or two of this, they cease to be convoluted, and several unite together into tubes of larger diameter, which enter the rete testis under the name *tubuli recti*. The mode in which the tubuli terminate at the large end of the lobule has not been clearly made-out, owing partly to the number of their

FIG. 308.

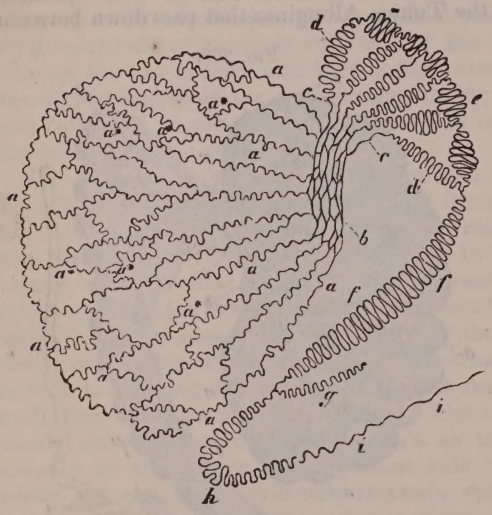


Human Testis, injected with mercury as completely as possible: *a*, *a*, lobules formed of seminiferous tubes; *b*, rete testis; *c*, vasa efferentia; *d*, flexures of the efferent vessels passing into the head, *e*, *e*, of the epididymis; *f*, body of the epididymis; *g*, appendix; *h*, cauda; *i*, vas deferens.

* V. Lavalette St. George, Stricker's "Handbook of Histology," Syd. Soc. Trans., 1872, vol. ii. p. 139; and Klein and Noble's "Atlas of Histology," pp. 270-272.

anastomoses; it is probably either by cæcal endings or by loops. The diameter of the tubuli is for the most part very uniform; in the natural condition they seem to vary from about the 1-195th to the 1–70th of an inch; but when injected with mercury, they are distended to a size nearly double the smaller of these dimensions.—The *rete testis* (*b*) consists of from seven to thirteen vessels, which run in a waving course, anastomose with each other, and again divide, being all connected together. Each tubulus, and each vessel of the rete testis, consists of a hyaline membrana propria lined with a single layer of short transparent columnar cells. The *vasa efferentia* (*c*), which pass to the head of the epididymis, are at first straight, but soon become convoluted (*d*), each forming a sort of cone, of which the apex is directed towards the rete testis, the base to the head of the epididymis (*e*). The number of these is stated to vary from nine to thirty; and their length to be about eight inches. The *epididymis* (*f*) consists of a very convoluted canal, the length of which is about twenty-one feet. Into its lower extremity, that is, the angle which it makes where it terminates in the vas deferens, is attached an appendix (*g*) composed of one or more *vasa aberrantia;* which, like the epididymis, are lined with columnar ciliated epithelium. Their special function is unknown. The nerves of the testis are stated by Letzerich* to pierce the membrana propria of the tubuli seminiferi, and end in a more or less irregular pyramidal mass of protoplasm, in which lie clear elliptic nuclei. The ends of the fibres, therefore, lie in close relation to the outer layer of secreting cells. The lymphatic channels in the testis are numerous, and in the epididymis extend as a delicate meshwork of vessels as far as the vas deferens.

Fig. 309.



Plan of the structure of the *Testis* and *Epididymis*:—*a*, *a*, seminiferous tubes; *a**, *a**, their anastomoses; the other references as in the last figure.

690. The fluid secreted by the Testis is invariably alkaline in Man, and is mingled, during or previously to its emission, with fluid secreted by the Vesiculæ Seminales, the Prostate, Cowper's glands, &c.; and it cannot, therefore, be obtained pure, except by drawing it from the testicle itself. No accurate analysis of it has been made in the human subject; but Kölliker† has made the following analysis of it in the Bull and Stallion:—

	Bull.	Stallion.
Water	820·60	819·40
Solid residue	179·40	180·60
Spermatin and Extractives	153·0	164·49
Fat	21·6	—
Salts	26·37	16·11

* Virchow's "Archiv," March, 1868.

† v. Gorup-Besanez, 1862, "Phys. Chem.," p. 424.

Frerichs,* on examining the contents of the Testes of a Rabbit, a Cock, and a Carp, found pure Semen to be a milky fluid of a mucous consistence, and neutral or slightly-alkaline reaction. That of the Bull is acid (Miescher). The principal organic substances of the mature semen in the Salmon are thus given by Miescher†:—Nuclein, 48·68 per cent.; Protamin ($C_9H_{20}N_5O_2$), 26·76; Albuminous Compounds, 10·32; Lecithin, 7·47; Cholesterin, 2·24; Fat, 4·53. The spermatozoa of the Bull contain no Protamin, but consist of Nuclein (50 per cent.), Albumin, and a body containing much phosphorus. Protamin is a non-crystallized substance of glutinous consistence, soluble in water, to which it gives an alkaline reaction, and is insoluble in alcohol and ether. It combines both with metallic bases and with acids. A substance named Spermatin, resembling alkali albumin, and mucin, has also been obtained from Semen. The ashes contain 5 per cent. of phosphate of lime. The spermatozoa evince little tendency to decomposition, and offer considerable resistance to the action of sulphuric, nitric, hydrochloric, and acetic acids, and to caustic alkalies at ordinary temperatures. The fluid portion of the secretion is a thin solution of mucus, which, in addition to the animal matter, contains chloride of sodium, and small quantities of alkaline sulphates and phosphates. When allowed to evaporate spontaneously, crystals appear, which are composed either of ammonio-magnesium phosphate, or, as Böttcher thinks, of albumin. The peculiar odour which the Semen possesses does not appear to belong to the proper spermatic fluid; but is probably derived from one or other of the secretions with which it is mingled.—The product of the secretion of each Testis is conveyed away by a single *vas deferens* (*i*), which is a cylindrical canal, having, within its fibrous wall, a circular longitudinal layer of non-striated muscular fibre, and being lined by a proper mucous membrane. The vas deferens, ascending into the abdominal cavity as a part of the spermatic cord, reaches the fundus of the bladder; and there it comes into proximity with the *Vesicula Seminalis* of its own side, with whose duct it unites to form the *ejaculatory duct* which terminates on the *verumontanum* of the urethra. It has been commonly supposed that the *vesiculæ seminales* stand to the *vasa deferentia* in the same light that the gall-bladder stands to the hepatic duct—namely, as a receptacle into which the seminal fluid may regurgitate, and within which it may accumulate; but (as Hunter was the first to maintain) this is not the case, since the fluid that is found in them is not semen, and but rarely contains even a small admixture of seminal fluid.‡ Moreover, these organs are not simple vesicles, but have a sacculated glandular character; and their secretion seems to be of a mucous nature. Into the same part of the urethra is discharged the secretion of the *Prostate Gland*, which is poured forth by a number (15–20) of separate ducts into a depressed fossa on either side; of the nature of this secretion scarcely anything is known; it contains 98·5 per cent. of water, and it may be surmised that its use, like that of the fluid of the vesiculæ seminales, is to dilute the seminal fluid, and to give it such an increase of bulk that it may be more effectually conveyed within the female passages. It seems probable, indeed, that a certain dilution of the fluid secreted by the testes may be a condition of its power of fecundation; since it has been ascertained by Mr. Newport, that too copious an application of spermatozoa to an ovum is absolutely unfavourable to their action.—That in some way or other both these glandular bodies serve as accessory organs of generation, may be inferred from the fact, that in animals which have only a periodical aptitude for pro-

* Art. 'Semen,' in "Cyclop. of Anat. and Physiol.," vol. iv. p. 506.

† Quoted in v. Gorup-Besanez, "Physiolog. Chemie," 1874, p. 463.

‡ See Art. 'Vesiculæ Seminales,' in "Cyclop. of Anat. and Physiol.," vol. iv. p. 1431.

creation, they undergo an alternate increase and decrease, corresponding with the periodical enlargement and diminution of the testes themselves. The essential peculiarity of the Spermatic fluid, however, consists in the presence of a large number of very minute bodies, the *spermatozoa*, which, from their usually remaining in active motion for some time after they have quitted the living organism, have been erroneously considered as proper Animalcules. The Human Spermatozoon (of which representations are given in Plate I., Fig. 1; whilst some of the principal forms in other animals are shown in Fig. 310) consists of a small oval flattened discoid 'head,' 5 μ* in length and 1–2 μ in thickness, an intermediate portion 6 μ in length, from which proceeds a long filiform 'tail' gradually tapering to the finest point, of 50 μ in length. The whole is perfectly transparent; and nothing that can be termed 'structure' can be satisfactorily distinguished within it.† Its movements are principally executed by the tail, which has a kind of vibratile undulating motion, by means of which the head is driven forwards. The rate of progression of spermatozoa has been stated to be ·004 mm. per second; and they move with sufficient force to displace calcareous particles ten times their own bulk. Their movements may continue for many hours after the emission of the fluid; and they are not checked by its admixture with other secretions, such as the urine and the prostatic fluid. Thus, in cases of nocturnal emission, the spermatozoa may not unfrequently be found actively moving through the urine in the morning; and those contained in the seminal fluid collected from females that have just copulated, are frequently found to live many days. As in the case of ciliated epithelium, the movements are rapidly arrested by weak acids, whilst they are stimulated by alkalies. They cease when the

* μ = ·001 of a millimètre.

† The characteristic forms of the spermatozoa of the various classes of the Vertebrata, are beautifully represented by Schweigger-Seidel in Max Schultze's "Mikroskop. Anat.," Band i. p. 309. He describes each spermatozoon as consisting of a head, body, and tail, the latter, as in some tritons, having a membrane attached to it, which performs undulatory movements. Grohe (Virchow's "Archiv," Band xxxii. p. 401) attributes the movements of the spermatozoa to the contractile protoplasm contained in the 'head' of the zooid; Bizzozero to that in the cilium or tail. See also v. Lavalette St. George, Art. 'Testes,' in Stricker's "Hum. and Comp. Histology," Syd. Soc. Transl., 1872, vol. ii. p. 149; Heneage Gibbes ('On the Structure of the Vertebrate Spermatozoon,' "Quarterly Journal of Microscopical Science," vol. xix. p. 487) distinguishes two distinct substances in the Spermatozoon, one in the head, the second forming the filament. This author also shows that the spermatozoon in the salamander and triton, and probably also in Mammalia consists of (*a*) a long head; (*b*) an elliptical portion connecting it with (*c*) the filiform body; (*d*) a very fine long thread, which is united to the body by (*e*) a homogeneous membrane. The motive power lies in a great measure in the filament, and the membrane attaching it to the body. The head of the spermatozoon is enclosed in a sheath which is the continuation of the membrane which surrounds the filament, and connects it to the body.

spermatozoa are exposed to a temperature of 120° F.,* but frozen spermatozoa recommence movements on being thawed.

691. The mode of evolution of the Spermatozoa,† which are undoubtedly true products of the formative action of the organs in which they are found, and cannot be ranked in the same category with the Protozoa, probably varies in different animals, so that in one the entire sperm-cell with all its parts is converted into a Spermatozoon (Schweigger-Seidel); in another the Spermatozoon proceeds exclusively from the nucleus (Kölliker), and in another it originates from the nucleus which remains as the head, and the cell-protoplasm which develops into the tail (v. Lavalette St. George).‡ This latter theory has been adopted by Klein,§ who states that certain cells lying nearest to the lumen of the seminal tubes, and named *spermatoblasts*, undergo changes which result in the nuclei becoming excentric, flattened, and oblong, forming the head, which is probably invested by a covering of the cell substance. The tail of the spermatozoon is formed by the rest of the cell contents, which is at first club-shaped, but is afterwards modified into a long, thin, and homogenous filament. M. Duval,‖ on the other hand, states that at puberty, amongst the epithelial cells lining the tubuli seminiferi, large cells may be distinguished, which he names 'mother cells,' and which result from the development of the primitive globules. These cells are comparable with the ovule of the female. Ch. Robin names them 'male ovules.' In different animals these cells proliferate either by endogenous multiplication or by gemmation, and give rise to a group of young cells named spermatoblasts, each of which becomes a spermatozoon. This change is completed, and the spermatozoa become free in the epididymis. The protoplasm of the spermatoblast forms the nuclear enlargement of the head of the spermatozoon and the tail, but it is doubtful whether the nucleus is preserved in the head. Besides the cells already described, numerous molecules are found in the semen. Mr. Gulliver describes them as resembling oil-particles, and varying in diameter from 1–20,000th to 1–8000th of an inch. They are always present, but are particularly abundant in birds and reptiles, when the testes begin to enlarge in spring, and become scanty as soon as the spermatozoa are completely developed. And the same is true for Man just before and after the attainment of the age of puberty.

692. That the Spermatozoa are the essential elements of the spermatic fluid, may be reasonably inferred from several considerations. There are some cases in which the 'liquor seminis' is altogether absent, so that they constitute the sole element of the semen; whilst, on the other hand, they are never wanting in the semen of animals capable of procreation; but are absent or imperfectly developed in the semen of hybrids, which are nearly or entirely sterile. Moreover, it may be considered as certain that the absolute contact

* See Bizzozero, "Annali Universali," vol. clxxxvii.

† For researches on the development, &c. of the Spermatozoa, see the elaborate Article 'Semen,' in the "Cyclop. of Anat. and Physiol.," by Drs. Wagner and Leuckart; Prof. Kölliker's "Manual of Microscopic Anatomy," 1860; Schweigger-Seidel in Max Schultze's "Archiv f. Mikroskop. Anat.," Band i. p. 309; v. Lavalette St. George, Stricker's "Human and Comp. Histology," vol. ii. 1872, p. 131; Merkel, "Reichert's Archiv," 1871, p. 644; Neumann ("Centralblatt," 1872, p. 881) contends that Spermatozoa are merely detached cilia developed from the epithelial cells lining the tubuli testis. See also v. Ebner, Reichert's "Archiv," 1872, p. 250; Henle, "Handbuch," Band ii. p. 356. G. Balbiani, "Leçons sur la génération des Vertébrés," Paris, 1879; J. E. Blomfield, "Quarterly Journ. Micros. Sci.," vol. xx. p. 80.

‡ Kölliker's views on the development of the spermatozoa are illustrated in Plate I., Figs. 2 and 3.

§ "Atlas of Histology," pp. 272–276.

‖ "Récherches sur la Spermatogenèse," Paris, 1878.

of the spermatozoa with the ovum is requisite for its fecundation; whilst, on the other hand, if the spermatozoa be carefully removed from the liquor seminis by filtration, the latter is entirely destitute of fertilizing power.* Hence the presence of the Liquor Seminis must be considered as merely incidental; and as answering some secondary purpose, either in the development or in the conveyance of the Spermatozoa. Henle† observes that whilst the Spermatozoa retain their vitality even in extreme old age, they are frequently absent in the seminal fluid of those suffering from disease.‡

693. The power of procreation does not usually exist in the Human Male before the age of from 14 to 16 years; and it may be considered probable that no Spermatozoa are produced until that period, although a fluid is secreted by the testes. At this epoch, which is ordinarily designated as that of *Puberty*, a considerable change takes place in the bodily constitution; the sexual organs undergo a much increased development; various parts of the surface, especially the chin and the pubis, become covered with hair; the larynx enlarges, and the voice becomes lower in pitch, as well as rougher and more powerful; and new feelings and desires are awakened in the mind. Instances, however, are by no means rare, in which these changes occur at a much earlier period; the full development of the generative organs, with manifestations of the sexual passion, having been observed in children but a few years old. The procreative power may last, if not abused, during a very prolonged period. Undoubted instances of virility at the age of more than 100 years are on record; but in these cases the general bodily vigour was preserved in a very remarkable degree. The ordinary rule seems to be, that sexual power is not retained by the male, to any considerable amount, after the age of 60 or 65 years.

694. To the use of the sexual organs for the continuance of his race, Man is prompted by a powerful instinctive desire (§ 510), which he shares with the lower animals. This Instinct, like the other propensities, is excited by sensations; and these may either originate in the sexual organs themselves, or may be excited through the organs of special sense. Thus in Man it is most powerfully aroused by impressions conveyed through the sight or the touch; but in many other animals, the auditory and olfactory organs communicate impressions which have an equal power; and it is not improbable that, in certain morbidly-excited states of feeling, the same may be the case in ourselves. Localized sensations have also a very powerful effect in exciting sexual desire, as must have been within the experience of almost every one; the fact is most remarkable, however, in cases of Satyriasis, which disease is generally found to be connected with some obvious cause of irritation of the generative system, such as pruritus, active congestion, &c. That some part of the Encephalon is the seat of this as of other instinctive propensities appears from

* This point was completely established by the researches of Mr. Newport ("Phil. Trans.," 1851), who repeated and confirmed the experimental results previously obtained by Spallanzani and by Prévost and Dumas.

† "Anatomie des Menschen," p. 357.

‡ This observation has been supported by Mantegazza and Bozzi, who found that in 88 cases of various forms of disease, on examination of the Testis the spermatozoa were deficient in both organs in 12 cases, and in one testis in 9 cases, whilst this could only be referred to organic lesion of the testis in two cases. Gulliver 'On the Semen and Seminal Tubes of Mammals and Birds' ("Proc. Zool. Soc.," July, 1842; and "Edin. Med. and Surg. Journ.," 1843, vol. lx. p. 158), also gives many examples of the absence of spermatozoa in cases of disease in Man and the lower Animals, and in birds during the winter. He has found that the spermatozoa of a particular genus may differ remarkably in chemical and other characters. Thus in the Fringillidæ they are quickly dissolved by acetic acid and other reagents, which have no action on the club-shaped spermatozoa of Hirundinidæ.

the considerations formerly adduced; but that the Cerebellum is the part in which this function is specially located cannot be regarded as by any means sufficiently proved (§§ 507–510). The instinct, when once aroused (even though very obscurely felt), acts upon the mental faculties and moral feelings; and thus becomes the source, though almost unconsciously so to the individual, of the tendency to form that kind of attachment towards one of the opposite sex which is known as *love*. This tendency cannot be regarded as a simple passion or emotion, since it is the result of the combined operations of the reason, the imagination, and the moral feelings; and it is in this engraftment (so to speak) of the physical attachment, upon the mere corporeal instinct, that a difference exists between the sexual relations of Man and those of the lower animals.

695. When, impelled by sexual excitement, the Male seeks intercourse with the Female, the erectile tissue of the genital organs becomes turgid with blood (§ 257), and the surface acquires a much increased sensibility; this is especially acute in the Glans penis. By the friction of the Glans against the rugous walls of the Vagina the excitement is increased; and the impression which is thus produced at last becomes so strong, that it calls forth, through the medium of a ganglionic centre, probably situated in the lower portion of the Spinal Cord, a reflex contraction of the muscular fibres of the Vasa Deferentia, and of the muscles which surround the Vesiculæ Seminales and Prostate gland. These receptacles discharge their contents into the Urethra; from which they are expelled with some degree of force, and with a kind of convulsive action, by its own Compressor muscles; whilst they are prevented from passing back into the bladder, according to Kobelt, by the great distension of the Verumontanum, which occurs during the period of erection. Now although the sensations concerned in this act are ordinarily most acutely pleasurable, there appears sufficient evidence that they are by no means essential to its performance; and that the impression which is conveyed to the Spinal Cord *need not* give rise to a sensation, in order to produce the reflex contraction of the Ejaculator muscles (§ 460). The high degree of nervous excitement which the act of coition involves, produces a subsequent depression to a corresponding amount; and the too frequent repetition of it is productive of consequences very injurious to the general health. This is still more the case with the solitary indulgence, which (it is to be feared) is practised by too many youths; for this, substituting an unnatural degree of one kind of excitement for that which is wanting in another, cannot but be still more trying to the bodily powers. The secretion of seminal fluid being, like other secretions, very much under the control of the nervous system, will be increased by the continual direction of the mind towards objects which awaken the sexual propensity (§ 680); and thus, if a frequent discharge be occasioned, whether by natural or unnatural excitement, a much larger quantity will altogether be produced, although the amount emitted at each period will be less, and its due perfection will not be attained, the fluid under such circumstances being found to contain an unduly-large proportion of immature seminal cells. The formation of the secretion seems of itself to be a much greater tax upon the corporeal powers than might have been supposed *à priori*; and it is a well-known fact, that the highest degree of bodily vigour is inconsistent with more than a very moderate indulgence in sexual intercourse; whilst nothing is more certain to reduce the powers, both of body and mind, than excess in this respect.—These principles, which are of great importance in the regulation of the health, are but expressions of the general law (which prevails equally in the Vegetable and in the Animal kingdom), that the Development

of the Individual and the Reproduction of the Species stand in an inverse ratio to each other, as has been well shown by Herbert Spencer.*

3. *Action of the Female.*

696. The essential part of the Female Generative system is that in which the Ova are prepared; the other organs are merely accessory, and are not to be found in a large proportion of the Animal kingdom. In many of the lower animals, the Ovarium consists of a loose tissue containing many areolæ, in which the Ova are formed, and from which they escape by the rupture of the cell walls; in the higher animals, as in the Human female, the substance of the Ovarium is firm and compact, and consists of a nucleated, tough, fibrous, connective tissue, with much interspersed fusiform muscular tissue forming what is known as the *stroma*. It originates in a small outgrowth of the inner surface of the Wolffian body, the regular columnar epithelial investment of which, probably derived from the epiblast, and contrasting strongly with the flattened epithelium of the rest of the peritoneal cavity, is thickened at this spot. The epithelium is the rudiment of the Graafian follicles and ova, whilst the out-growth is destined to form the vascular stroma of the ovary. As development proceeds the cells of the superficial columnar, or so-called germ epithelium multiply, and single cells or groups of cells, round, ovoid, or tubular, come to be enclosed in the tissue of the ovary by delicate vascular processes which shoot forth from the stroma. These cells constitute the primordial ova,† each of which is therefore a persistent cell of a peculiar epithelial formation. When mature a primordial ovum has a diameter of 200 μ (and

† For the literature of the Histology of the Ovaries up to 1871, see Art. 'Ovary and Paro-varium,' by W. Waldeyer, in Stricker's "Hum. and Comp. Histology," Syd. Soc. transl., 1872, vol. ii. p. 164. Since then there have appeared Kapff, Reichert's "Archiv," 1872, p. 513, Foulis, "Trans. Royal Soc., Edinburgh," vol. xxvii. and Sernoff, "Centralblatt f. die Med. Wiss.," 1874, p. 481, denying, and Romiti, Schultze's "Archiv," Band x. p. 201, Born, Reichert's "Archiv," 1874, p. 118, and to a certain extent Balfour, "Quart. Journ. Micros. Sci.," vol. xviii. (1878), p. 383, and Klein, "Atlas of Histology," p. 291, corroborating Waldeyer's histological observations.

since μ represents a micromillimètre or 0·0000032809 of an inch, 200 μ would equal ·00065618, or about 1–524th of an inch), and is contained within a capsule termed the Graafian follicle or ovisac.* In a large Graafian follicle we may distinguish a connective tissue investing membrane, which is composed of two layers, the *tunica fibrosa* (*g*, Fig. 311), and the *tunica propria folliculi* (*h*); the latter is lined on its internal surface by several layers of cells, of which the nearest to the tunica propria are columnar, whilst the deeper ones are transparent and polyhedral (*i*), constituting the epithelium of the follicle, or *membrana granulosa*. The membrana granulosa is collected round each ovum into a disk-like investment termed the *discus proligerus* (*e*, Fig. 311), and the remainder of the follicular cavity contains a clear fluid, the *liquor folliculi*. The earliest rudiment of every ovum consists of a simple cell with soft granular protoplasm unenclosed by a

membrane, a nucleus and a nucleolus. The protoplasm of the primordial cell is termed the formative or principal yolk, since it alone undergoes segmentation and development. The nucleus is termed the germinal vesicle (*Vesicula germinativa*) (*c*, Fig. 312; *v g*, Fig. 313), and the nucleolus, the germinal spot (*Macula germinativa*) (*d*, Fig. 312; *t g*, Fig. 313). According to Van Beneden,† the germinal vesicle in the ovum of the rabbit, and probably also of other mammalia, includes a clear liquid which is traversed by a granular substance,

the nucleoplasm, which often forms a reticulum. Whilst still within the Graafian follicle the ovum becomes surrounded by a series of secondary formations, which are collectively to be regarded as products of the follicular epithelium. To these belong the vitelline membrane, or membrane enclosing the yolk, which on account of its thickness and peculiar transparency has received in Mammalia the distinctive appellation of *Zona pellucida** (*b*, Fig. 312; *m v*, Fig. 313), and the food yolk or secondary yolk. The zona pellucida in Mammals appears to be perforated by numerous fine pores, which confer upon it a striated aspect; through these pores it is supposed that the substance of the epithelial cells immediately surrounding the zona pellucida is continued in the form of fine threads; it is highly elastic, and when torn with needles the edges roll back and the contents issue in a stream. It resists to a considerable degree the action of acids and alkalies. When mature the Human Ovum is extremely minute; not measuring above 1-120th of an inch in diameter, and being sometimes no more than half that size. The diameter of the germinal vesicle of the Human ovum has not yet been ascertained, owing to the difficulty of isolating it from the yolk; in the ovum of the Rabbit, it is about 1-720th, and in the Guinea Pig about 1-1800th of an inch; and that of the germinal spot, in the Mammalia generally, is from 1-3600th to 1-2400th of an inch.

697. In Plate I. Fig. 4, is represented the condition of the Graafian vesicles in various stages of development, as they are seen imbedded in the fibrous stroma of the ovarium, in a thin section from the ovary of a sow three weeks

FIG. 313.

old. The ovum at first occupies the centre of the Graafian vesicle, but it subsequently removes to its periphery; and, when the contents of the ovisac are undergoing maturation, prior to their escape, the ovum is always found on the side of it nearest to the surface of the ovary. The proper Ovisac, whose wall is formed of a non-vascular membrane, is surrounded by a vascular layer, which is formed by a condensation of the ordinary stroma of the ovarium; it is this which is usually described as the outer layer of the Graafian vesicle.

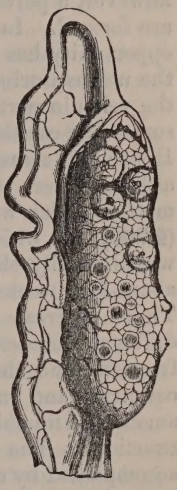
698. A continual change seems to be taking place in the contents of the Ovarium during the greater part of life; certain of the Ovisacs or Graafian vesicles, and their contents, successively arriving at maturity, whilst others degenerate and die. According to the valuable inquiries of Dr. Ritchie,† it appears that even during the period of childhood, there is a continual rupture

* Foulis (loc. cit., p. 378), in opposition to other observers, states that the vitelline membrane is formed by a hardening of the outer part of the yolk.

† "London Medical Gazette," 1844. See also Foulis, "Brit. Med Journ.," 1875, p. 841.

of ovisacs and discharge of ova, at the surface of the ovarium. The Ovaria are studded with numerous minute copper-coloured maculæ, and their surface presents delicate vesicular elevations, which are occasioned by the most matured ovisacs; the dehiscence of these takes place by minute punctiform openings in the peritoneal coat, and no cicatrix is left. At the period of puberty, the stroma of the ovaries is crowded with ovisacs; which are still so minute, that in the Ox (according to Dr. Barry's computation) a cubic inch would contain 200 *millions* of them. The greatest advance is seen in those which are situated nearest the surface of the Ovarium; and in such, the Graafian vesicle, with its two coats, may be distinctly traced. In those animals whose aptitude for conception is periodical, the development of the ova to such a degree that they become prepared for fecundation, is periodical also. This development is made evident when the parts are examined in an animal which is 'in heat,' by the projection of the Graafian vesicles from the surface (Fig. 314); and it consists not merely in an increase of size, but in certain internal changes presently to be described (§ 703).

Fig. 314.



Ovarium of the Rabbit, at the period of Heat; showing various stages of the extrusion of ova.

699. In the Human female, the period of *Puberty*, or commencing aptitude for procreation, is usually between the 13th and 16th years; it is generally thought to be somewhat earlier in warm climates than in cold;* and in densely-populated manufacturing towns than in thinly-peopled agricultural districts. The mental and bodily habits of the individual have also considerable influence upon the time of its occurrence; girls brought up in the midst of luxury or sensual indulgence undergoing this change earlier than those reared in hardihood and self-denial. The changes in which puberty consists are for the most part connected with the Reproductive system. The external and internal organs of generation undergo a considerable increase of size; the mammary glands enlarge; and a deposition of fat takes place in the mammæ and on the pubes, as well as over the whole surface of the body, giving to the person that roundness and fulness which are so attractive to the opposite sex at the period of commencing womanhood. The first appearance of the Catamenia usually occurs whilst these changes are in progress, and is a decided indication of the arrival of the period of puberty; but it is not unfrequently delayed much longer; and its absence is by no means to be

* It has been stated, by almost all physiological writers, that women (like fruits) reach maturity, and that menstruation commences, much earlier in hot climates, particularly between the tropics, than in temperate and very cold countries. From many elaborate and interesting papers which have been published within a few years, however, especially from those of Mr. Roberton of Manchester (collected in his "Essays on Menstruation, and on Practical Midwifery," 1851), it would seem that the natural period of puberty in temperate climates occurs in a much more extended range of ages, and is much more equally distributed through that range, than others have alleged; and that, in other countries, the supposed parallel between plants and fruits does not hold good. The fact seems to be that this, like other *periodic* phenomena of warm-blooded animals, is but little influenced by external temperature, simply because the rate of growth and development, of which these phenomena are the exponents, is determined by the temperature of the body itself, not by that of the surrounding medium. Still it is quite possible that external warmth may have a slight influence in determining early puberty; since, as already shown, it tends to maintain a somewhat higher degree of bodily heat (§ 396). According to Szukitz, the average age at which the catamenia appear amongst German women is 15½ years; according to Brierre de Boismont, it occurs a year earlier in Parisian girls. See Henle and Meissner's "Bericht," 1857, p. 606.

regarded as a proof of the want of aptitude for procreation, since many women have borne large families without having ever menstruated. The Catamenial discharge, as it issues from the uterus, appears to be nearly or quite identical with ordinary blood; but in its passage through the vagina, it becomes mixed with the acid mucus exuded from its walls, which usually deprives it of the power of coagulating. If the discharge should be profuse, however, a portion of its fibrin remains unaffected, and soft and diffluent clots are formed. In cases in which, by the death of women at this period, an opportunity has been afforded for the examination of the lining membrane of the uterus during menstruation, it is found to be unusually turgid with blood, the veins in particular being much distended, and opening upon the internal surface by capillary orifices, to which valvules are occasionally found attached.* Hence it is scarcely correct to designate the menstrual flux as a 'secretion;' although there is reason to think that it may carry off, besides blood, certain matters which would be appropriate to the formation of a Decidual membrane (§ 700), but which, if not so employed, become excrementitious.—The interval which usually elapses between the successive appearances of the discharge, is about four weeks; and the duration of the flow is from three to six days. There is great variety in this respect, however, among the inhabitants of different climates, and among individuals; in general, the appearance is more frequent, and the duration of the flow greater, among the residents in warm countries, and among individuals of luxurious habits and relaxed frame, than among the inhabitants of colder climes, or among individuals inured to bodily exertion. The first appearance of the discharge is usually preceded and accompanied by considerable general disturbance of the system, especially pain in the loins and a sense of fatigue in the lower extremities; and its periodical return is often attended with the like symptoms, which are more or less severe in different individuals.

700. Much discussion has taken place respecting the causes and purposes of the Menstrual flow; and modern inquiries have thrown great light upon them.† The state of the female generative system, during its continuance, appears to be analogous to the *heat* or periodic sexual excitement of the lower animals; some of which have a sero-sanguinolent discharge at that period, and among many of which the ova are entirely extruded by the female before the spermatic fluid of the male reaches them, this occasionally taking place even in Birds. There is good reason to believe that in the Human female the sexual feeling becomes stronger at the period of menstruation; and it is quite certain that there is a greater aptitude for Conception, immediately before and after the epoch, than there is at any intermediate period. Observations to this effect were made by Hippocrates, and were confirmed by Boerhaave and Haller; indeed, coitus immediately after menstruation appears to have been frequently recommended as a cure for sterility, and to have proved successful. This question has been made the subject of special inquiry by M. Raciborski; who affirms that the exceptions to the rule—that conception occurs immediately before or after, or during menstruation—are not more than 6 or 7 per cent. Indeed, in his latest work on the subject,‡ he gives the details of 15 cases, in which the date of conception could be accurately fixed, and the time of the last appearance of the catamenia was also known; and in all but one of them,

* See Whitehead "On Abortion and Sterility," pp. 13–37.

† For an excellent example of the absurd superstitions which still cling to the Menstrual period, and which will one day form an interesting and instructive chapter in Medicinal Folk Lore, see "The British Medical Journal," vol. ii. 1879, in which evidence is adduced from various sources to show that meat salted by a menstruating woman will certainly spoil.

‡ "Sur la Ponte des Mammifères," Paris, 1844. See also "Lancet," 1871, vol. i. p. 421.

the correspondence between the two periods was very close. Even in the exceptional case, the catamenia made their appearance shortly after the coitus, which took place at about the middle of the interval between the two regular periods. When conception occurs immediately before the menstrual period, the catamenia sometimes appear, and sometimes are absent; if they appear, their duration is generally less than usual. The fact that conception often takes place immediately *before* the last appearance of the catamenia (and not *after* it, as commonly imagined), is one well-known to practical men.—Numerous cases have been collected by Mr. Girdwood, Dr. Robert Lee, MM. Gendrin, Negrier, Raciborski, and others, in which the menstrual period was evidently connected with the maturation and discharge of the ova;* but the most complete observations yet made on the subject, are those of Dr. Ritchie (loc. cit.). He states that about the period of puberty a marked change usually takes place in the mode in which the ovisacs discharge their contents; but that this change does not necessarily occur simultaneously with the first appearance of the catamenia; as in some cases the conditions which obtain in the period before puberty, are extended into that of menstruation. The ovaries now receive a much larger supply of blood; the ovisacs show a great increase in bulk and vascularity, so that, when they appear at the surface of the ovary, they present themselves as pisiform turgid elevations; and the discharge of their contents leaves a much larger cicatrix, and is accompanied by an effusion of blood into their cavity, with other subsequent changes to be presently described. It would appear, however, that although such a discharge takes place *most frequently* at the menstrual period, yet the two occurrences are not necessarily co-existent; for menstruation may take place without any such rupture; whilst, on the other hand, the maturation and discharge of mature ova may occur in the intervals of menstruation, and even at periods of life when that function is not taking place. Perhaps the most correct general statement on the subject would be this: that there is a periodic return of Ovarian excitement, which *tends to* the maturation and extrusion of ovules, though it may not always reach that point; whilst there is also a periodic turgescence of the vessels of the lining membrane of the Uterus, which *tends to* the production of a decidual membrane;—but that these two periods, though usually coincident, are not necessarily so; and that either change *may* occur without the concurrence of the other. Thus removal of the ovaries, especially when the operation is performed before the age of puberty, is usually followed by arrest of the menses, though cases are on record in which menstruation occurred after extirpation of both ovaries.

701. The duration of the period of aptitude for procreation, as marked by the persistence of the Catamenia, is more limited in Women than in Men, usually terminating at about the 45th year; it is sometimes prolonged, however, for ten or even fifteen years further; but cases are rare in which women above 50 years of age have borne children. The time of the cessation of the flow is known as the Menopause; it occurs gradually, and with it are lost many of the peculiar sexual characteristics.† There is usually no menstrual flow

* Such, at least, appears to be the legitimate inference from the state of the Ovaries; but the cases are very few in which the extruded Ova have been found in the female passages. Two such cases (one of them, however, not altogether satisfactory) were recorded by Dr. Letheby in "Philos. Transact.," 1852.

† Dr. Matthews Duncan has clearly shown ("Trans. Roy. Soc. of Edin.," vol. xxiii. p. 186) that the total fertility of fertile women diminishes as the age at which marriage takes place increases. Sterility is rare amongst those marrying between the ages of 20 and 24, but about 7 per cent. of those marrying between 15 and 20 are sterile. These last, however, where fertile, bear more children than those marrying at a later date.

during pregnancy and lactation; in fact, the cessation of the catamenia is generally one of the first signs indicating that conception has taken place. But it is by no means uncommon for them to appear once or twice subsequently to conception; and in some women there is a regular monthly discharge, though probably not of the usual character, through the whole period. Some very anomalous cases are on record in which the catamenia never appeared at any other time than during pregnancy, and were then regular. The absence of the catamenia during lactation is by no means constant, especially if the period be prolonged, though as a rule they reappear about the tenth month; when the menstrual discharge occurs, it may be considered as indicating an aptitude for conception; and it is well-known that, although pregnancy seldom recurs during the continuance of lactation, the rule is by no means invariable. In women who do not suckle menstruation recurs within six weeks after confinement.

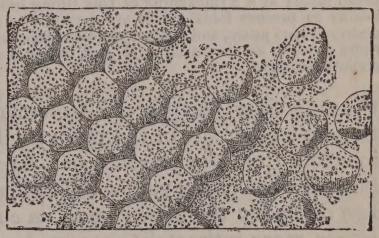
702. The function of the Female, during the coitus, is essentially passive. When the sexual feeling is strongly excited, there is a considerable degree of turgescence in the erectile tissue surrounding the vagina, and composing the greater part of the nymphæ and the clitoris; and there is an increased secretion from various glandular follicles.* But these changes are by no means necessary for effectual coition; since it is a fact well established, that fruitful intercourse may take place when the female is in a state of narcotism, of somnambulism, or even of profound ordinary sleep. It has been supposed by some that the os uteri dilates,† by a kind of reflex action, to receive the semen; but the introduction of a small quantity of the fluid just within the vagina, appears to be all that is absolutely necessary for conception; for there are many cases on record in which pregnancy has occurred, in spite of the closure of the entrance to the vagina by a strong membrane in which but a very small aperture existed. That the spermatozoa make their way towards the ovarium, and fecundate the ovum either before it entirely quits the ovisac or very shortly afterwards, appears to be the general rule in regard to the Mammalia; and their power of movement must obviously be both vigorous and long-continued to enable them to traverse so great an extent of mucous membrane, especially when it is remembered that they ascend in opposition to the direction of the ciliary movement of the epithelial cells, and to the downward peristaltic action of the Fallopian tubes, which may generally be noticed in animals killed soon after sexual intercourse.—We shall now consider the changes in the Ovum and its appendages, by which it is prepared for fecundation.

* The glands of Duverney or Bartholin, which were very accurately described by Professor Tiedemann (1840), and subsequently by M. Huguier in the "Archives d'Anatomie" (1847), seem to be analogous to Cowper's glands, and, like them, are sometimes wanting and differ in size. In advanced age they are said to diminish in size, and even to disappear. They are present in the females of all animals where Cowper's glands exist in the males, and are structurally large compound tubular mucous glands. They secrete a thick, tenacious, greyish-white fluid, which is emitted in large quantity at the termination of the sexual act, most likely from the spasmodic contraction of the constrictor vaginæ muscle, under which they lie. Its admixture with the male semen has been supposed to have some connexion with impregnation; but no proof whatever has been given that any such admixture is necessary. It seems not improbable, however, that it may serve, like the prostatic fluid of the male, to give a *dilution* to the seminal fluid that is favourable to its action (§ 690). These glands were probably known to the ancients; and it is doubtless their secretion which Hippocrates and others described as the female semen.

† See cases reported by Litzmann in 1846, and by Dr. J. R. Beck ("Med. and Surg. Reporter," 1872, No. 15), which seem to show that the uterus may participate rather actively in the process of impregnation. The latter observer noticed that the os uteri opened and closed with considerable energy on mechanical stimulation.

703. Up to the period when the Ovum is nearly brought to maturity, it remains in the centre of the ovisac or inner layer of the Graafian follicle; and it is supported in its place by the 'membrana granulosa,' which is continuous with its proligerous disk. The movement of the ovum towards the surface, which has been already referred to as a part of the changes by which it is prepared for fecundation, appears from the observations of Valentin to be due to the following cause:—In the immature ovisac, the space between its inner layer and the ovum is for the most part filled up with cells; these, however, gradually dissolve away, especially on the side nearest the surface of the ovary; whilst an albuminous fluid is effused from the deeper part of the ovisac, which pushes the residual layer (forming the discus proligerus) before it, and thus carries it against the opposite wall. At the same time, there is a gradual thinning away of the various envelopes of the Graafian follicle, as well as of its own walls, in the situation of its most projecting part; and thus it is preparing to give way at that point for the discharge of the contained ovum. Before rupture takes place, however, the ovisac itself undergoes a considerable change. Its walls become more vascular externally, and are thickened on their interior by the deposit of a fleshy-looking substance, which in many of the lower Mammalia is of a reddish colour, whilst in the Human female it is rather of a yellowish hue. This substance, known as the *Corpus luteum*, is at first entirely composed of an aggregation of cells (Fig. 315), and may, in fact, be considered as an increased development, or hypertrophy, of the 'membrana granulosa' or epithelial lining of the ovisac. Into this hypertrophied portion grow capillary blood-vessels, carrying with them migratory cells. The cavity of the follicle is thus gradually filled up with the hypertrophied epithelium, and the blood-vessels and pigment cells. The central portion becomes converted into gelatinous tissue, whilst the peripheral parts become hypertrophied and folded, the cells undergo fatty degeneration, the oil particles at first separate, ultimately coalesce, and press the nucleus to the side of the cell. In most domestic quadrupeds, this growth, which sprouts like a mass of granulations from the lining of the ovisac, is often so abundant, if the ovum be impregnated, as not only to fill the cavity of the ruptured vesicle, but even to protrude from the orifice on the surface of the ovary; this orifice subsequently closes, and the contained growth becomes gradually firmer, its colour changing from red to yellow. In the Human female, however, as in the Sow, this new formation is at first less abundant; it does not form mammillary projections from the interior of the ovisac, but lies as a uniform layer upon its lining; and this is thrown into wrinkles or folds, in consequence of the contraction of the ovisac (Fig. 316, *a*—*d*). An irregular cavity is thus at first left in the interior of the ovisac, after the discharge of the ovum; but this gradually diminishes, partly in consequence of the increased growth of the yellow substance, and partly owing to the general contraction of the ovisac, until it is at last nearly obliterated or reduced to a sort of stellate cicatrix (*e*—*h*). An effusion of blood usually takes place into this cavity, in the Human female, at the time of the rupture of the ovisac; but the coagulum which is left takes no share in the formation of the yellow body. It generally loses its colouring matter,

Fig. 315.

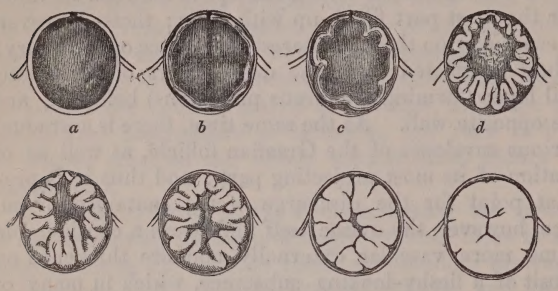


Cells forming the original substance of the *Corpus Luteum*.

and acquires the characters of a fibrinous clot; and this may either form a sort of membranous sac lining the cavity, or it may become a solid mass occupying the centre of the stellate cicatrix.*

704. The latter part of the history of the Corpus Luteum is greatly influenced by the impregnation or non-impregnation of the Ovum whose extrusion it has followed.—If conception do not take place, the corpus luteum seldom attains a size greater than that of a small pea, and is very commonly less than this; and it begins to diminish about the time of the next menstruation, its shape, which was at first globular, becoming somewhat collapsed and flattened. This diminution is due in the first instance to the absorption of part of its contained coagulum, which usually at the same time loses part of its colouring matter; but contemporaneously with this, there is an increase in the proper yellow substance, which also becomes brighter in colour from the presence of a large quantity of oleaginous matter in its cells. Soon, however, the yellow substance becomes softer and more friable, showing less distinctly the markings of its convolutions; whilst at the same time it becomes more intimately connected with the neighbouring tissues. The central coagulum becomes a faint, whitish, stellate cicatrix; and the yellow substance assumes various irregularities of form, and gradually decreases in size. As a general rule, the corpus luteum of the non-pregnant female is reduced within six or eight weeks to a very insignificant size; but it may then remain almost unchanged for many months: so that, in the ovaries of females who have menstruated regularly, numerous obsolete corpora lutea may be distinguished. —But if, on the other hand, the discharged ovum should be fertilized, and pregnancy should supervene, the corpus luteum instead of reaching its maximum of development in three or four weeks, and then undergoing atrophy, continues to develop itself for a considerable period, and does not, in fact, become very decidedly retrograde, until after the termination of gestation. This difference relates not only to its size, but also to its aspect and general characters. Its size appears to be usually greatest between the third and the sixth months of pregnancy; it retains its globular or only slightly flattened form; and it continues to give to the touch a sense of considerable resistance and solidity. The convoluted wall of yellow substance becomes much thicker in proportion to the space in its interior; so that whilst in the non-impregnated female its thickness never exceeds one-eighth of an inch, and is usually much less, that of the pregnant female measures as much as

FIG. 316.



Successive stages of the formation of the *Corpus Luteum* in the Graafian follicle of the Sow, as seen in vertical section: at *a* is shown the state of the follicle immediately after the expulsion of the ovum, its cavity being filled with blood, and no ostensible increase of its epithelial lining having yet taken place; at *b*, a thickening of this lining has become apparent; at *c*, it begins to present folds which are deepened at *d*, and the clot of blood is absorbed *pari passu*, and at the same time decolorized; a continuance of the same process, as shown at *e*, *f*, *g*, *h*, forms the Corpus Luteum, with its stellate cicatrix.

* This process was first accurately described by M. Pouchet, in his "Théorie Positive de l'Ovulation spontanée," 1847. See also Dr. Charles Creighton, 'A Theory on the Homology of the Supra-renals,' "Journal of Anatomy and Physiology," vol. xiii. (1879), p. 72.

from three-sixteenths to one-fourth of an inch. This substance, moreover, acquires a firmer and more highly organized structure; but instead of presenting an increased brightness of colour, it fades to a dusky and indefinite hue. As, from the time that impregnation takes place, the periodical activity of the ovary is suspended, no new vesicles protrude themselves from its surface until after the completion of gestation; and even those which, at the date of conception, happened to be more or less prominent, appear again to recede. Hence, if the period of pregnancy be at all advanced, the corpus luteum is not found, like that of menstruation, in company with unruptured vesicles in active process of development. After parturition, the corpus luteum rapidly diminishes; though its characteristic structure is still to be distinguished for many months, by close inspection.* Many Graafian follicles previous to the age of puberty undergo a similar process of degradation, but in no case is it then carried to so great an extent.†

705. The foregoing differences (whose ordinary existence may be considered as well established, although it may not be affirmed that they present themselves characteristically in each individual case) are probably to be attributed to the increased determination of blood which takes place to the whole generative apparatus, when it is in a state of exalted functional activity. It is a question, however, of much scientific interest, and one that occasionally becomes of importance in Juridical investigations, what degree of resemblance may exist between the corpus luteum which is formed after the mere extrusion of an ovule, and that which has been modified by the supervention of pregnancy. For it is unquestionable that an unusual development of the fibro-cellular substance may sometimes occur without impregnation; whilst, on the other hand, the changes which usually follow impregnation may take place so much less characteristically than usual, that the corpus luteum, even at the middle period of pregnancy, may be no larger than that which is often found where pregnancy has not occurred. These variations, which seem mainly to depend upon differences in the degree of vascular excitement of the ovaries accompanying and succeeding the extrusion of ova, render it impossible to draw any definite line of demarcation by which we may at once determine what are, and what are not, the results of conception; but the following practical rules, deduced from a consideration of all the circumstances yet known, may be laid down for the guidance of those who find it desirable to have some standard of judgment:—"1. A Corpus Luteum, in its earliest stage (that is, a large vesicle filled with coagulated blood, having a ruptured orifice, and a thin layer of yellow matter in its walls), affords no proof of impregnation having taken place.—2. From the presence of a Corpus Luteum, the opening of which is closed, and the cavity reduced or obliterated, only a stellate cicatrix remaining, and if the Corpus Luteum be of small size, not containing as much yellow substance as would form a mass the size of a small pea, no conclusion as to pregnancy having existed, or fecundation having occurred can be drawn.—3. A similar Corpus Luteum, of larger size than a common pea, would be strong presumptive evidence not only of impregnation having taken place, but of pregnancy having existed during several weeks at least; and the evidence would approximate more and

more to complete proof, in proportion as the size of the corpus luteum was greater."*

706. Since the discharge of matured Ova from the ovaries takes place as independently of sexual intercourse in the Human female (and in the Mammalia generally) as it does in those animals whose ova are fertilized out of the body, it seems unnecessary that the seminal fluid should reach the ovarium in order to effect the fertilization of the ova, since this end may be answered by the contact of the two in the Fallopian tubes, or even in the Uterus itself. From the experiments of Bischoff, however, it appears that in rabbits, bitches, and probably in most other Mammalia, sexual union usually takes place previously to the escape of the ova from the ovary, and that sufficient time often elapses for the seminal fluid to reach the ovary before their extrusion occurs: in such cases, therefore, it would seem probable that fecundation is effected at the ovary itself. That such occasionally happens in the Human female, seems to be unequivocally proved by the occurrence of tubal or even of ovarian fœtation; the ovum having received the fertilizing influence immediately upon quitting the ovisac, or even before it has entirely extricated itself from the ovary, and having been in some way checked in its transit towards the uterus, so that its development has taken place in the spot at which it has been arrested. It is affirmed by Bischoff that by the time the ovum reaches the uterus, or even the lower end of the Fallopian tube, its capacity for impregnation is lost; but this assertion chiefly rests on the cessation of sexual desire observed in those animals in which, after death, the ova were found in these situations. There is every reason to believe that this is not the case in the Human female; for although the sexual desire may be the strongest about the period of the maturation and escape of the ova, yet it is by no means wanting at other times; and the occasional occurrence of cases in which impregnation has taken place from a single coitus in the middle of the interval between the menstrual periods, shows either that the ovum may retain its capacity for impregnation for some time after its escape from the ovary, or that its maturation and extrusion are not by any means invariably coincident with the menstrual period.† The ova, when set free from the ovaries by the rupture of the ovisacs and the giving-way of their several envelopes, and surrounded by the cells of the discus proligerus, are received by the fimbriated extremities of the Fallopian tubes, which, during the period of sexual excitement, appear to be closely applied to the surface of the ovaries. Their conveyance along the Fallopian tubes is probably due in part to the peristaltic movement of their walls, and in part to the action of the cilia which clothe their internal surface.

707. The object of the changes which have been already described, is to bring the Ovum within the reach of the fecundating influence, and to convey it into the uterus after it has been fertilized; we have now to consider the changes of the Ovum itself, which take place during the same epoch. Special attention has been devoted during the last few years by various observers‡ to

* See Dr. Baly's "Supplement to Müller's Physiology," p. 57.

† See a case of this kind recorded by Dr. Oldham in the "Medical Gazette," July 13, 1849.—Instances are certainly not unfrequent, in which conception has taken place five or six days after the conclusion of the menstrual period; the Author has himself known one in which this occurred, after the menstrual flow itself had persisted for a week. It has been urged that the known fertility of Jewish females, who abstain from sexual intercourse for eight days, or even thirteen days, after the termination of the catamenia, is opposed to the idea that the menstrual period is that of 'heat;' but there is reason to believe that this is to be accounted for in another way—namely, by the usual occurrence of conception from intercourse immediately *before* the access of the catamenia. (See Mr. Girdwood, in the "Lancet," Dec. 14, 1844.)

‡ Accounts of the recent investigations in regard to the changes taking place in the ovum

the observation of certain phenomena presented by the ovum previous to and immediately succeeding its impregnation. The researches have been carried on for the most part with the eggs of the rabbit amongst Mammalia; and of Asterias, and certain of the Vermes amongst the Invertebrata, but there appears reason to suppose that the results thus obtained hold good for ova generally. Previous to fertilization, when the ovum is mature, but in the majority of cases before it has left the ovary, the germinal vesicle which occupied a central position moves towards the periphery of the yolk; it always takes up its position at the precise point of the zona pellucida, which is nearest the ovisac, and which is therefore closest to the surface of the ovary. The membrane surrounding the germinal vesicle is then absorbed, the germinal spot is broken up and disappears, and a portion of the vesicle itself seems to undergo absorption. The remainder of the germinal vesicle elongates (Fig. 327, *a*), and is converted into a spindle-shaped body (*b*), of which the middle portion is striated longitudinally, each of the striæ presenting about its centre a thickened portion composed of fine granules (*c*). The spindle then travels to the surface of the ovum where it divides into two portions; one lying in the space between the ovum and its surrounding membrane, and giving rise to the polar bodies: a second remaining within the egg and forming after division and subsequent aggregation the *female pronucleus*. The extrusion of the polar bodies or directive corpuscles generally occurs in the case of rabbits just after the ovum has entered the Fallopian tube. Spermatozoa coming in contact by their heads with the ovum at this period, become enveloped in the surrounding mucilaginous coat. A prominence from the protoplasm of the egg is put out until it reaches the nearest spermatozoon, which then makes its way into the egg through the projecting portion. The head alone of the spermatozoon appears to enter the egg, the tail, which remains visible for some time on the exterior, ultimately undergoes certain changes and disappears, apparently owing to its fusion with the protoplasm of the egg. At the instant of contact of the spermatozoon with the egg, the most external layer of protoplasm separates itself and forms a membrane, thereby preventing the entrance of more spermatozoa. The head which has thus entered forms the male pronucleus, it grows in size, whilst the protoplasm immediately surrounding it assumes a radiating arrangement. *The male pronucleus* thus formed travels towards the female pronucleus, with which it ultimately coalesces to produce the first segmentation nucleus, the subsequent changes in which will be presently noticed (§ 734). Commenting upon these phenomena, Mr. Balfour observes,* "that the act of impregnation is seen to consist essentially in the fusion of the male and female nucleus: not only does this appear in the actual fusion of the two pronuclei, but it is brought into still greater prominence by the fact that the female pronucleus is a product of the nucleus of a primitive ovum, and the male pronucleus is the metamorphosed *head* of the spermatozoon, which is itself developed from the nucleus of a spermatic cell. The spermatic cells originate from cells identical with the primitive ova, so that the fusion which takes place is the fusion of morphologically similar parts in the two sexes."† In the Osseous Fishes it has been shown by Dr.

previous to fertilization may be read in Oellacher, "Archiv f. Mikros. Anat." viii. p. 24; Prof. Van Beneden's Paper, "Quarterly Journ. Microscop. Sci." vol. xvi. (1876), p. 153; and in Summaries by Priestley, *ib.* p. 130; and Balfour, *ib.* vol. xviii. p. 108. In each paper full bibliographies will be found.

* Op. cit. vol. xviii. p. 129.

† The results of Newport's experiments upon the fertilization of ova will be found in the "Philosoph. Trans.," 1851, p. 178, and 1853, pp. 266–281. See also Huxley on the 'Development of Pyrosoma,' "Linn. Trans.," vol. xxiii. p. 227, and "Ann. Nat. Hist.," ser. 3, vol. v. pp. 29–35. See also Dr. Barry, in "Philosoph. Transact.," 1840, p. 533; and Dr. Ransome, in

Ransom that the spermatozoa pass through a minute opening in the external membrane of the ova, termed the *micropyle*. A similar opening has been observed by Müller and others in Insects, Acephalous Mollusks, and in several Echinodermata; and its use, as Dr. Allen Thompson has suggested, is probably to facilitate the fecundation of ova possessed of very thick external coverings. A micropyle has not been seen in any of the Mammalia, though the point has been closely investigated by Reichert in the Guinea Pig. It has been remarked by Mr. Newport, that spermatozoa whose spontaneous *motility* has ceased, no longer possess the fecundating power; and this fact concurs with other phenomena to indicate, that it is not only a certain *material*, but a *vital force* of which that material is (so to speak) the vehicle, which is required to effect this most important operation.

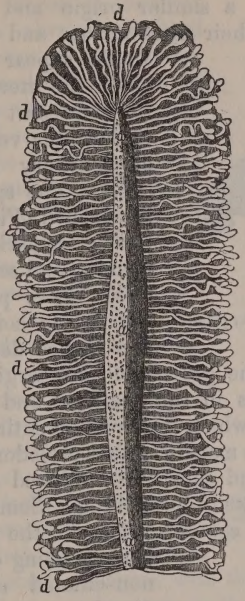
708. Having thus noticed the principal points of the history of the development and impregnation of the Ovum, we shall proceed to consider the provisions made for the Nutrition of the Embryo, through the generative apparatus of its female Parent, up to the time of parturition; deferring the history of its own Development for that separate consideration which the importance of this subject demands (Sect. 4).—About the time that the ovum is leaving the ovary, the cells of the proligerous disk which immediately surrounds the zona pellucida become club-shaped; their small ends being applied to the surface of the ovum, so as to give it somewhat of a stellate appearance. According to Bischoff, these cells entirely disappear from the ovum of the Rabbit as soon as it has entered the Fallopian tube: whilst in the Bitch they become round, and continue to invest the ovum in this form throughout its whole transit to the uterus. During its passage, the ovum acquires a sort of gelatinous envelope, which is enclosed in a membrane of fibrous tissue, termed the *Chorion*. This envelope is probably of an *albuminous* nature, corresponding with the 'white' of the Bird's egg; whilst the fibrous texture of the chorion seems to be produced, like the membranous basis of the egg-shell of the bird, by the exudation of fibrin from the lining membrane of the Fallopian tube or oviduct. The outer layer of this envelope, in the egg of the Bird, is consolidated by the deposition of particles of carbonate of lime in its areola; and none of it undergoes any further organization. The Chorion of the Mammal, on the other hand, is destined to undergo changes of a much higher order, which adapt it for participating to a most important degree in the nutrition of the included embryo. The first of these changes consists in the extension of the cellular surface of the membrane into a number of villous prolongations, which give it a spongy or shaggy appearance (Fig. 321). These processes are very largely developed in the human ovum, and form the *chorion frondosum;* they serve as absorbing radicles, and act as the channels through which the embryo is nourished by the fluids of the parent,

"Proceed. of Roy. Soc.," Nov. 23, 1854. Bischoff (Henle and Pfeuffer's "Zeits.," 1865, p. 268) considers that, in the majority of cases, the act of fecundation occurs whilst the ovum is traversing the Fallopian tube. According to Coste, the duration of the passage of the egg through the oviduct of the fowl varies from four to six hours, and of its retention in the cloaca four hours; whilst Foster & Balfour ("Elements of Embryology," p. 21) state that it remains in the oviduct for a period of 24 hours. The influence of a single act of coition in the fowl, according to the same observer, may extend to from five to six eggs, which may be laid during the eleven to seventeen subsequent days. Harvey extended the influence even to twenty eggs. His agrees with Coste, and observes, that in all probability these eggs were impregnated at different periods: and hence may proceed some of the variations in point of development of the cicatricula. His has also observed that the eggs of fowl, laid in the middle of summer, are more advanced, and develop with greater rapidity than those laid towards the end of autumn

until a more perfect communication is formed by the subsequent extension of vessels into them.

709. We have now to speak of the changes in the Uterus which take place in consequence of Conception, and which prepare it to receive the ovum.* Of these the most important is the formation of the *Membrana Decidua*, so called because the greater portion of it is cast-off at each parturition. Professor Turner has pointed out that as soon as the ovum is received into the uterus, the mucous membrane swells; and there is reason to suppose that certain changes, closely resembling those which take place at each menstrual period, are set up in the uterus before the ovum reaches it. Thus the ciliated *epithelium* often, though not always, loses its columnar form, and the cells multiply in order to cover the increased surface. The *submucous tissue* increases enormously, which is due to the multiplication and development of the corpuscles which are abundantly distributed through its tissue. The *branched glands* naturally present, as seen in vertical sections, are separated to a much greater distance from each other in consequence of the growth of the sub-epithelial tissue, and are augmented in size. The whole membrane becomes much more vascular. On its surface pit-like depressions may be seen, which were formerly thought to be the enlarged mouths of the glands, but which Professor Turner has ascertained to be new-formed pits or *crypts in the interglandular tissue*. Into these crypts the villi of the chorion penetrate. During menstruation the thickness of the mucous membrane is increased as above described; but by a retrogressive process the epithelium and the greater part of the glands and mucous membrane then undergo a fatty degeneration and are finally detached. If, however, the ovum which is discharged at this period be fecundated, these changes do not pass into the retrograde stage, but advance to the hypertrophy which gives rise to the decidua.

Fig. 317. Fig. 318.



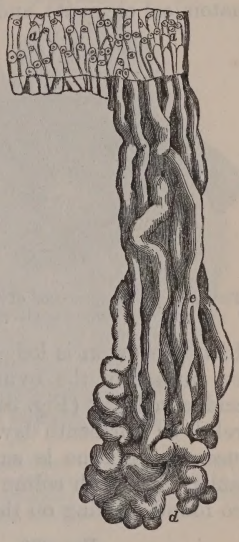


Fig. 317. Section of the *Lining Membrane of a Human Uterus* at the period of commencing pregnancy, twice the natural size; showing the arrangement and other peculiarities of the glands *d*, *d*, *d*, with their orifices *a*, *a*, *a*, on the internal surface of the organ.

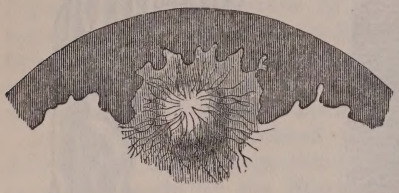
Fig. 318. A portion of Fig. 317 more enlarged, showing the convoluted extremities of the tubular glandulæ.

710. The Deciduous membrane is found at a later period to consist of two

* See Williams, 'On the Structure of the Uterine Mucous Membrane,' "Obstet. Journal," 1875, Nos. 23 and 24.

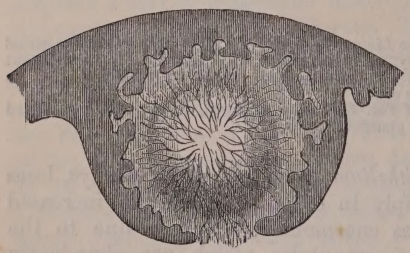
layers: the *Decidua vera* lining the uterus, and the *Decidua reflexa* covering the exterior of the ovum. The observations of M. Coste, Dr. Farre and De Sinéty* show that there is considerable resemblance between the two at an early period, since they have a similar origin and consist of the same anatomical elements, and from their observations and those of Reichert,† it would appear that when the ovum enters the uterus, it becomes attached to some part of a triangular area of the decidua vera, on which numerous cotyledonary elevations or islands exist. The spot at which the ovum is attached (Fig. 319) ceases to grow, but a remarkable development of primary and secondary papillary processes takes place in the adjoining islands, in consequence of which a cup-shaped depression is formed, in which the ovum is lodged. The growth of the margin of the cup over the free surface of the ovum, closes in the chamber and forms the membrana decidua reflexa‡ (Fig. 320), by which the ovum is entirely covered about the twelfth or thirteenth day. At the margin of the cotyledonary island, the uterine mucous membrane is smooth and shows the widened orifices of the uterine glands, lined with columnar ciliated epithelium. Some utricular glands are also found opening on the inner concave surface of the reflexa, the rest of the surface being covered with a short, non-ciliated cylindrical epithelium. As the ovum increases in size, the cavity between the decidua vera and the decidua reflexa, or, as it is sometimes termed, the uterine chamber, which communicates by its superior angles with the Fallopian tubes, and below with the canal of the cervix, gradually diminishes, and by the end of the third month either the two layers come into contact and are henceforth indistinguishable—the whole cavity of the uterus being occupied by the fœtal chamber—or, as Dr. Farre suggests, the decidua reflexa may, after first becoming extremely attenuated, ultimately entirely vanish. De Sinéty§ shows that to the end of pregnancy, remains of the uterine glands lined with columnar epithelium may be found in certain parts of the cavity of the uterus; after delivery, however, no epithelium can be discovered, but in its place are a number of cells presenting embryonal characters, which infiltrate the whole tissue. That portion of the decidua vera in which the chorionic tufts are embedded, and which afterwards forms the maternal portion of the placenta, is termed the *Decidua Serotina;* the greater portion of it is deciduous at parturition.

Fig. 319.



First stage of the formation of the *Decidua reflexa* around the Ovum.

Fig. 320.



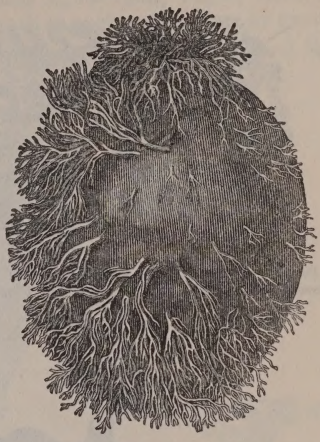
More advanced stage of the *Decidua reflexa.*

711. The surface of the Ovum, thus surrounded by the double layer of the deciduous membrane, and during the first three or four weeks lying loose in the fœtal chamber, is rendered shaggy by the growth of villous tufts from the

* "Archiv de Physiol," 1876, p. 342. † Reichert's "Archiv," 1873, p. 127.
‡ See 'Turner's Report,' "Journal of Anatomy and Physiology," vol. viii. p. 168.
§ Loc. cit.

surface of its investing Chorion (Fig. 321), by which it begins to be attached to the walls that surround it. Each of these tufts, as was first pointed out by Prof. Goodsir (loc. cit.), is composed of an assemblage of nucleated cells, which are found in various stages of development; and these are always enclosed within a layer of basement-membrane, which seems to be itself composed of flattened cells united by their edges.* At the free extremity of each villus is a bulbous expansion, the cells composing which are arranged round a central spot; and it is at this point that the most active processes of growth take place, the villus elongating by the development of new cells from its germinal spot, and (like the spongiole of the plant) drawing in nutriment from the soil in which it is imbedded. —In its earliest grade of development, the chorion and its villi contain no vessels; and the fluid drawn in by the tufts is communicated to the embryo by the absorbing powers of the germinal membrane of the latter. But when the tufts are penetrated by blood-vessels, an event which occurs about the third or fourth week according to Kölliker,† and their communication with the embryo becomes more direct, the means by which they communicate with the parent are found to be still essentially the same; namely, a double layer of nucleated cells, one layer belonging to the fœtal tuft, and the other to the vascular maternal surface. It is from these elements that the *Placenta* is formed.‡

Fig. 321.



Entire *Human Ovum* of eighth week, sixteen lines in length (not reckoning the tufts); the surface of the Chorion partly smooth, and partly rendered shaggy by the growth of tufts.

712. The first stage in this process consists in the extension of the Fœtal vessels into the villi of the Chorion over its entire surface, in the manner hereafter to be detailed; so that the nutriment which these villi imbibe, instead of being merely added to the albuminous fluid surrounding the yolk-bag, is now conveyed directly to the embryo. This—the earliest and simplest mode by which the Fœtus effects a new connection with the parent—is the only one in which it ever takes place in the lower Mammalia, which are hence properly designated as 'non-placental,' rather than as ovo-viviparous. In the higher Mammalia, however, there soon occurs a great extension of the vascular tufts of the fœtal chorion, at certain points; and a corresponding adaptation, on the part of the uterine structure, to afford them an increased supply of nutritious fluid. These specially prolonged portions are scattered in the Ruminantia and some other Mammalia, over the whole surface of the chorion, forming what are termed the 'cotyledons;' but in the higher orders, and in Man,

* Kölliker, "Entwickelungsgesch. des Mensch.," 1879, p. 334. † Loc. cit., p. 367.

‡ The Placenta varies in form to a considerable extent in different animals. In Cetacea and in many Ungulata, as the Llama, Horse and Zebra, the villi project from all parts of the chorion, and their placenta is consequently termed *diffuse*. In Carnivora, in Seals, in the Elephant and Hyrax, the villi are only developed in a ring or zone around the chorion, and the placenta is therefore called *zonary*. In Ruminants the villi are developed in certain spots, irregularly distributed over the chorion, forming the *cotyledonous* placenta. Finally, in Man and in Rodents the villi are limited to a single spot, and the Placenta is thence termed *discoid*. See report of Turner's Lectures delivered at the College of Surgeons in "Lancet" for June, 1875, and in "Journal of Anat. and Physiol.," vol. x. p. 127.

they are concentrated in one spot, forming the Placenta. In some of the lower tribes the maternal and the fœtal portions of the placenta may be very easily separated; the former consisting of the thickened Decidua, and the latter being composed of the prolonged and ramifying vascular tufts of the Chorion, dipping down into it. But in the Human placenta the two elements are mingled together through its whole substance.—On looking at the fœtal surface of the Human placenta, we perceive that the umbilical vessels diverge in every direction from the point at which they enter it; and their subdivisions form a large mass of capillaries, arranged in a peculiar manner (Figs. 322, 323), and constituting what is known as the *fœtal villi*. Each villus contains one or more capillary loops, communicating with an artery on one side, and with a vein on the other: but the same capillary may pass into several villi, before re-entering a larger vessel. The capillaries of the villi are covered, as in the chorion, by a layer of cells (Fig. 323, *a*, *a*; Fig. 324, *e*), enclosed in a basement-membrane; but the fœtal tuft thus formed is enclosed in a second series of envelopes (Fig. 324, *a*, *c*, *e*), derived from the maternal portion of the placenta —a space (*ips*) being left, however, between the two, at the extremity of the tuft.

Fig. 322.

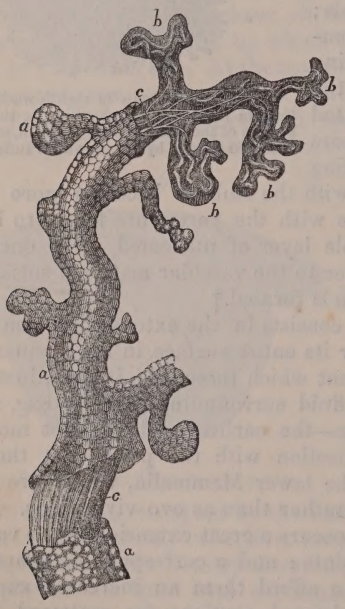
Fig. 323.



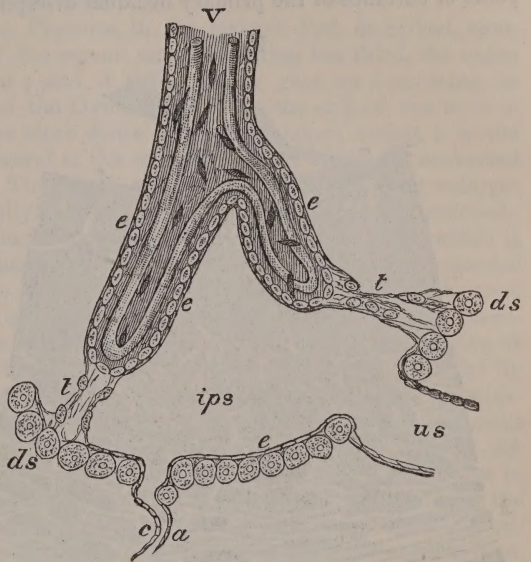
Portion of one of the *Fœtal Villi*, about to form part of the Placenta, highly magnified:—*a a*, its cellular covering; *b*, *b*, *b*, its looped vessels; *c*, *c*, its basis of connective tissue.

713. Whilst the *fœtal* portion of the Placenta is thus being generated by the extension of the vascular tufts of the Chorion, the maternal portion is formed by the enlargement of the vessels of the Decidua, between which they dip down. "These vessels assume the character of sinuses; and at last swell out (so to speak) around and between the villi; so that finally the villi are completely bound up or covered by the membrane which constitutes the walls of the vessels, this membrane following the contour of all the villi, and even passing to a certain extent over the branches and stems of the tufts. Between this membrane, or wall of the enlarged decidual vessels, and the internal membrane of the villi, there still remains a layer of the cells of the decidua."* In

* Prof. Goodsir's "Anatomical and Pathological Observations," p. 60. Prof. Turner "Journ. of Anat. and Physiology," 1873, p. 130) has recently demonstrated, however, that

this manner is formed the *maternal* portion of the placenta, which may be regarded in its adult state (as was well pointed out by Dr. J. Reid*) in the light of a large sac formed by a prolongation of the inner coat of uterine vessels; against the fœtal surface of which sac the tufts just described may be said to push themselves, so as to dip down into it, carrying before them a portion of its thin wall, which constitutes a sheath to each tuft. Now as every extension of the uterine vessels carries the decidua before it, every one of the vascular tufts that dips down into it will be covered with a layer of the cellular structure of the latter; and the fœtal portion of each tuft will thus during the earlier periods of intra-uterine life be generally enclosed in a layer of *maternal* cells and basement membrane (Fig. 323, *a*, *b*, *c*).† From observations made by Kölliker it appears that the fœtal villi are not in direct connection with the uterine glands, which soon shrink and disappear, but lie in the substance of the decidua in inter-glandular spaces. Reichert, however, states that he has seen the villi enter the mouths of the glands. The whole interior of the Placental cavity soon becomes (Fig. 325) intersected by numerous tufts of fœtal vessels disposed in fringes, and bound down by reflexions of the delicate membrane that forms its proper wall; just as the intestines are held in their places by the reflexions of the peritoneum that covers them. This view was suggested to Dr. Reid by the very interesting fact, that the tufts of fœtal vessels not unfrequently extend beyond the uterine surface of the placenta, and dip down into the uterine sinuses, where they are still covered and held in their places by reflexions of the same membrane. All the bands which connect and tie down the tufts are formed of the same elements as the envelopes of the tufts themselves; namely a fold of the lining membrane of the decidual sinuses, and a layer of the cellular decidua.

Fig. 324.



V, Placental Villus, consisting of gelatinous connective tissue with corpuscles; in its interior are seen the fœtal blood-vessels forming loops; *e*, *e*, epithelium investing the Villus, beneath which is a layer of cells forming the occluding lamina; *d s*, decidua serotina; *c*, *a*, curling artery; *u s*, uterine sinus; *t*, *t*, trabecula; *ips*, intra-placental maternal blood sinus.

the *decidua serotina* does not form a complete and continuous membranous septum between the uterus and placenta, but that its continuity is in various localities interrupted to allow of the penetration of many of the placental villi into the utero-placental vessels, into which they project free and naked.

See also Masquelin and Swaen 'Premières phases du développement du Placenta maternel chez le lapin,' "Archiv. de Biologie" (1880), tom. i. pp. 25–44.

714. The Maternal blood is conveyed into the Placental cavity by the 'curling arterics' of the uterus (Fig. 324, *c*, *a*, Fig. 325 *d*); and is received back from it into the large veins that are commonly designated as sinuses (Fig. 325, *b*, *b*). "The utero-placental sinus-system of veins is so related to the placenta as to communicate with the interior of the cotyledons, either at the outer edge of the placenta, where the so-called circular sinus lies, or where the sinuses lie within the inter-cotyledonary decidual dissepiments, or where they come into contact with the uterine face of the placenta, close to the plane of entrance of the primary decidual dissepiments into its substance. The communication is not as if the sinuses terminated abruptly by open mouths, as has already been described, but rather by possessing cribriform apertures in their walls as they lie in contact with the placenta. From the relation of the sinuses to the margins of the cotyledons, whilst the curling arteries penetrate their uterine surface near their centre, the stream of maternal blood passes through each cotyledon from its centre to its circumference, and is effectually brought into contact with the whole of the fœtal villi." The fœtal vessels (Fig. 324, *e*, *e*; Fig. 325, *c*, *c*) being bathed in this blood, as the branchiæ of aquatic animals are in the water that surrounds them, not only enable the fœtal blood to exchange its venous character for the arterial, by parting with its carbonic acid to the maternal blood, and receiving oxygen from it; but they also serve as rootlets, by which certain nutritious elements of the maternal blood (probably those composing the liquor sanguinis) are taken into the system of the fœtus. In this, they closely correspond with the villi of the intestinal canal; and there is this further very striking analogy—that the nutrient material is selected and prepared by two sets of cells, one of which (the maternal) transmits it to the other (the fœtal), in the same manner as the epithelial cells of the intestinal villi seem to take up and prepare the nutrient matter, which is destined to be still further assimilated by the cells that float in the circulating current. It is probable, too, that the Placenta is to be regarded as an excreting organ; serving for the removal, through the maternal blood, of excrementitious matter whose continued circulation through the blood of the fœtus would be prejudicial to the latter. And it will be in this mode that the blood of the mother may become impregnated with substances, or impressed

Fig. 325.

with attributes, originally belonging to the male parent; so as to impart these to the products of subsequent conceptions by a different father.* There is no more direct communication between the mother and fœtus than that which is afforded by this immersion of the fœtal tufts in the maternal blood; all the observations which have been supposed to prove the existence of real vascular continuity, having been falsified by the extravasation of fluid, probably consequent upon the force used in injecting the vessels. Moreover, the different size of the blood corpuscles in the fœtus and in the parent shows the non-existence of any such communication.

715. The formation of the Placenta, in the manner just described, commences in the latter part of the second month; during the third, the organ acquires its proper character; and it subsequently goes on increasing, in accordance with the growth of the Ovum. Towards the end of the term of gestation, however, it becomes more dense and less vascular; owing, it would seem, to the obliteration of several of the minuter vessels, which are converted into hard fibrous filaments. The vessels of the Uterus undergo great enlargement throughout, but especially at the part to which the placenta is attached; and the blood in moving through them produces a peculiar murmur, which is usually distinctly audible at an early period of pregnancy, and may be regarded (when due care is taken to avoid sources of fallacy) as one of its most unequivocal positive signs. The 'placental bruit' is thus described by Dr. Montgomery:†—"The characters of this phenomenon are, a low murmuring or somewhat cooing sound, resembling that made by blowing gently over the lip of a wide-mouthed phial, and accompanied by a slight rushing noise, but without any sensation of impulse. The sound is, in its return, exactly synchronous with the pulse of the mother at the time of examination; and varies in the frequency of its repetitions, with any accidental variation which may occur in the maternal circulation. Its situation does not vary during the course of the same pregnancy; but in whatever region of the uterus it is first heard, it will in future be found, if recognized at all—for it is liable to intermissions—at least, we shall occasionally be unable to hear it where we have already heard it a short time before, and where we shall shortly again recognize it. According to my experience, it will be most frequently heard about the situation of the Fallopian tube of the right side; but it may be detected in any of the lateral or anterior parts of the uterus." That the cause of this sound exists in the Uterus itself, is distinctly proved by the fact, that it has been heard when that organ was so completely *anteverted*, that the fundus hung down between the patient's thighs. A sound so much resembling this as to be scarcely distinguishable from it, may be occasioned, however, by a cause of a very different nature—namely, an abdominal tumour, pressing upon the aorta, iliac arteries, or enlarged vessels of its own; and, in doubtful cases, it is necessary to give full weight to the possibility of such an explanation. The sound may be imitated at any time by pressing the stethoscope on the iliac arteries. The placental bruit has not unfrequently been heard in the eleventh week; but it cannot generally be detected before the fourth month, when the fundus uteri rises above the anterior wall of the pelvis.

716. The increase in the size of the Uterus, which takes place *pari passu* with the enlargement of the ovum, is accompanied by a remarkable augmentation in the amount of its substance. Up to about the fifth or sixth month,

* See, for various proofs that the mother may be *poisoned* through the presence of noxious substances in the blood of the fœtus, the Essay by Mr. Savory, entitled "An Experimental Enquiry into the Effect upon the Mother of Poisoning the Fœtus," London, 1858.

† "Signs of Pregnancy," p. 121.

not only its cavity, but the thickness of its walls, is progressively added to; from that time, to the end of gestation, the thickness of the walls diminishes whilst the cavity increases, but not in an equal proportion; and at the conclusion of parturition, its solid bulk is estimated at about twenty-four times that of the unimpregnated Uterus. The augmented volume of the organ is chiefly due to the increased development of its Muscular coat, which is composed of the fusiform cells with staff-shaped nuclei, that make up the 'non-striated' muscular fibre elsewhere. According to Prof. Kölliker, a vast amount of new fibres are generated during the early months of pregnancy; but there is at the same time an extraordinary increase in the size of those previously formed, their length being multiplied from seven to eleven times, and their width from twice to five times. After the sixth month the origination of new muscular fibres seems to cease, but the augmentation in the size of those already generated seems to continue. The connective tissue which unites the bundles of muscular fibres into plexuses, and which is very scanty in the unimpregnated uterus, also increases during pregnancy, and becomes more distinctly fibrous.*

717. *Innervation of the Uterus.*—The uterus receives its motor fibres from two sources, from the hypogastric nerves issuing from the posterior mesenteric ganglion, and also from nerves issuing from the sacral plexus. An antagonistic action appears to exist between these two sets of nerves.† If the Hypogastric branches be electrically stimulated, contractions of the circular fibres of the uterus takes place, the cervix descending into the vagina whilst the os opens. On the other hand, on stimulation of the sacral nerves, the longitudinal fibres are made to contract, the uterus becomes shorter and the os remains closed. Suppression of the respiration, or stimulation of the sciatic nerve, acts in a reflex manner, chiefly on the hypogastric nerves. The vessels of the uterus obtain their nerves from the same sources as the muscular tissue; the nervi hypogastrici supplying the constricting, and the sacral nerves the dilating fibres, which last can also be brought reflectorially into action through the sciatics. The nerves entering the mucous membrane are connected with ganglia. According to Lindgren,‡ the mucous membrane contains a rich plexus of medullated fibres, which near the epithelium of the free surface gives off bundles of very fine fibrils. It has been shown by Dr. Lee,§ in his beautiful preparations and drawings, that the Nerves of the Uterus, as well as the blood-vessels and lymphatics,‖ undergo a great augmentation during pregnancy. Simultaneously with the enlargement of the uterus, the Mammary gland and its appendages undergo a fuller development; and from this a valuable, but not unequivocal, indication of pregnancy may be drawn. Occasional shooting pains in the Mammæ are not unfrequently experienced within a short period after conception; and more continued tenderness is also not unusual. A sense of distension is very commonly experienced at about the end of the second month; and from that time a distinct 'knottiness' usually begins to present itself, increasing with the advance of pregnancy. In many instances, however, these mammary sympathies are entirely absent; and they may be simulated by changes that take place in consequence of

various affections of the uterus. A change of colour in the areola is a very common, but not an invariable, occurrence in the early months of pregnancy; but another sign is afforded by the areola and nipple, which is of more value because more constant—namely, a puffy turgescence, and an increased development of the little glandular follicles, or tubercles, which commonly secrete a dewy moisture.—Many other changes in the constitution occur during pregnancy, indicated by the buffiness of the blood, the irritability of the stomach, and the increased excitability of the mind. All these, however, are discussed with sufficient amplification in works on Obstetric Medicine.

718. The act of Conception, being one of a purely organic nature, is not itself productive of any sensation on the part of the mother; but there are some women in whom it is attended with certain sympathetic affections, such as faintness, vertigo, &c., that enable them to fix upon the particular time at which it has taken place. From that period, however, the mother has no direct consciousness of the change going on in the uterus (save by the effects of its increasing pressure on other parts), until the occurrence of what is termed 'quickening.' This is generally described as a kind of fluttering movement, attended with some degree of syncope or vertigo. After it has once occurred, and has strongly excited attention, it is occasionally renewed once or twice, and then gives place to the ordinary movements of the fœtus. Not unfrequently, however, no movement whatever is felt, until near the end of the term of gestation, or even through the whole of it. As to the cause of the Sensation, Obstetricians are much divided; and no satisfactory account has been given of it. It has been vulgarly supposed to be due to the first movement of the fœtus, which was imagined then to become possessed of an independent life; and the English law recognizes the truth of this doctrine, in varying the punishment of an attempt to procure Abortion, according to whether the woman be 'quick with child' or not; and in delaying execution when a woman can be proved to be so, though it is made to proceed if she is not, even if she be unquestionably pregnant. Whether or not the first *sensible* motions of the fœtus are the cause of the peculiar feeling in question, there can be no doubt that the embryo has as much independent vitality before, as after, the quickening. From the time that the ovum quits the ovary, it ceases to be a part of the parent, and is dependent on her only for a due supply of nourishment, which it converts by its own inherent powers into its proper fabric. But this dependence cannot be said to cease at the moment of quickening; for the connection must be prolonged during several weeks, before the fœtus becomes capable of sustaining life without such assistance. The earliest period at which this may occur, will be presently considered (§ 723).*

719. At the conclusion of about forty weeks or (less correctly) nine solar months,† from the period of conception, the time of Parturition arrives. In

* Oser and Schlesinger (Stricker's "Med. Jahrb.," 1872) have shown that powerful contractions of the uterus are produced by the circulation of dyspnœic arterial blood, partly owing to excitation of some centre for the uterine nerves existing in the cranium, and partly owing to irritation of excitable tissue in the uterus itself; and Schlesinger has further shown (Stricker's "Med. Jahrb.," 1873, p. 1) that uterine contractions can be induced by electric excitation of the centric extremity of a divided dorsal nerve. (For other experiments on the reflex contraction of the uterus after irritation of sensory nerves, see Spiegelberg, "Zeits. f. rat. Med.," 3 R. Band ii. 1858, Körner, "Studien des Phys. Inst. zu Breslau," Heft iii., and Obermeier, Pamphlet, Bonn, 1865.) Scanzoni found that irritation of the nipples, which, according to Luschka, contain so many tactile and Pacinian corpuscles, causes contraction of the uterus. The nerve plexus on the aorta is an important but not the only channel for the conduction of these motor impulses.

† Although nine calendar months, ten lunar months, forty weeks, or 280 days, is generally spoken of as the usual term of gestation, yet the real term exceeds this by from five to seven

this act, the muscular walls of the Uterus are primarily concerned; for a kind of peristaltic contraction takes place in them, the tendency of which is to press the contents of the cavity from the fundus towards the os uteri, and finally to expel them; and this contraction is alone sufficient to empty the uterus, when no impediment is presented to the exit of the fœtus, as we see in the occasional occurrence of *post-mortem* parturition. It is, in fact, in the contraction of the fibres of the fundus and body of the uterus, and in a relaxation of those about the cervix (which relaxation is something quite different from a mere yielding to pressure, and is obviously a vital phenomenon, that marks a peculiarity in the actions of this part), that the first stage of an ordinary labour essentially consists.* There is no proof whatever that these changes are dependent upon nervous influence; in fact, there is much evidence that the parturient action of the uterus is *not* the result (as some have maintained it to be) of a 'reflex' action of the Spinal Cord, but is due to its inherent contractility; for numerous instances have occurred in which normal parturition has taken place, notwithstanding the destruction of the lower part of the Cord, or the existence of a state of complete paraplegia which marked its functional inactivity; and the continuance of the peristaltic action for some time after somatic death, when neither the Cerebro-spinal nor the Sympathetic system can afford any supply of nervous power, is a yet more satisfactory proof of the same position.†—Nevertheless, it seems quite certain that muscular contractions of the Uterus *may be* induced by reflex action; for in no other way can we account for numerous phenomena, which distinctly mark the operation of remote causes acting through the nervous system; such as the induction of uterine contractions by the dash of cold water on the abdominal surface, by the injection of cold water into the vagina, by the ingestion of cold water into the stomach, or even by dipping the hand into cold water, or again by the suctorial application of the infant's lips to the nipple, by the introduction of the hand into the vagina, by violent movements of other parts of the body, by the presence of an excess of Carbonic acid in the blood, by anæmia produced by compression of the aorta, and by various other means. This general fact has an important practical bearing; since there are various occasions on which it is most important to life that the previously flaccid uterus should be excited to vigorous contraction, for the sake of accelerating parturition or of suppressing hæmorrhage; whilst, on the other hand, it is often no less important to be able to prevent or to antagonize the operation of causes which would prematurely induce uterine contractions, to the destruction of the offspring and the danger of the mother.

days, according to the months included. The mode of reckoning customary amongst women, is to date from the middle of the month after the last appearance of the catamenia: but it is certain that conception is much more likely to take place soon after they have ceased to flow, or even just before their access, than in the intervening period (§ 700), so that in the majority of cases it would be most correct to expect labour at forty weeks and a few days after the last recurrence of the menses. According to Dr. Matthews Duncan the interval between insemination and parturition is a period of 275 days. The interval between the disappearance of the last menses, and the period of parturition is considerably less than the usually assigned 280 days, and may be taken on the average to be 278 days. The real duration of pregnancy is, therefore, the period between conception and parturition, and this interval will be 275 days *minus* the interval between insemination and conception. Dr. Duncan, therefore, concludes that the 278th day after the last day of the last menses is the most *likely* one for parturition. The period of Quickening may be relied on in some women, in whom it occurs with great regularity in a certain week of pregnancy; but in general there is great latitude as to the time of its occurrence. The usual or average time seems to be about the 18th week of gestation.

* See a paper corroborating this statement, by Arthur Scott Dunkin, M.D., in "Edinb. Med. Journal," vol. ii. 1863, p. 523.

† See cases recorded in "Lancet," 1872, vol. i. pp. 517, 596.

720. When, in the normal act of Parturition, the head has so far made its way through the os uteri as to begin to distend the lower part of the genital canal, a new kind of expulsive effort is superadded to that of the Uterus itself; the assistance of the Expiratory muscles being then called in (§ 460), through the intermediation of the Spinal cord, which is probably excited to this action by the stimulus thus applied to the afferent nerves of the compressed parts; and it is chiefly by the instrumentality of these muscles that the normal act of parturition is usually completed. The same action which expels the fœtus, generally also detaches the placenta; and if the uterus contract with sufficient force after this has been thrown off, the orifices of the vessels which communicate with it are so effectually closed, that little or no hæmorrhage takes place. If, however, the uterus does not contract, or relaxes after having contracted, a large amount of blood may be lost in a short time from the open orifices. For some little time after parturition, a sero-sanguineous discharge, termed the *lochia*, is poured out from the uterus; and this commonly contains shreds of the deciduous membrane which had not been previously detached, together with a quantity of fat globules, and other products of disintegration of the uterine tissue.* Within a few weeks after delivery, the uterus regains (at least in a healthy subject) its previous condition; part of its newly-generated muscular fibres seem to disappear altogether, whilst the others shrink to their ordinary dimensions; and the portion of its mucous membrane which had been thrown-off as Decidua, seems to be to some extent reproduced. According to the researches of Dr. Matthews Duncan and M. Robin, this occurs even before delivery, so that the muscular tissue of the Uterus is never left completely denuded, though it does not become perfect until two months after delivery.†

721. As to the reason why the period of Parturition should be just forty weeks after the occurrence of Conception, we know nothing more than we do of that of similar *periodical* phenomena in the history of the life of Man and of other living beings; all of which must be considered as *occasional* manifestations of changes that are *constantly* in progress, whose rate, being dependent upon the degree of Heat supplied, is so uniform in warm-blooded amimals, as to secure a very close conformity to a common standard.‡ There is evidence that the occurrence of the uterine *nisus* may be induced by a variety of causes, several of which probably occur in the normal act of Parturition. For, in the first place, the state of development of the muscular substance of the Uterus can scarcely be without a considerable influence on this operation. We see it undergoing a gradual augmentation during the period of pregnancy, without any demand being made upon its functional activity; it gradually becomes more and more irritable, contractions being far more readily excited in it, by electrical or other stimulation, in the later than

* In addition to the evidence above referred to, of the rapid occurrence of fatty degeneration of the uterine structure after parturition, the Author may mention that he has been informed by Dr. Retzius (Professor of Midwifery at Stockholm) that he has detected a large number of fat-globules in the urine of puerperal women. Is it not possible—it may be further asked—that some of the oleaginous matter so copiously poured forth by the Mammary glands may be derived from this source? Such an economy of nutrient material would be consistent with what we elsewhere meet with; and the idea is conformable to the fact, that the proportion of butyrin in the milk is much greater in the earlier, than in the later months of lactation.

† See Huxley's "Elements of Comp. Anatomy," 1864, p. 107.

‡ This may be best illustrated by the analogy of a Leyden jar which is being charged by the *continuous* action of an Electrical Machine, and which is so arranged as to *dis*charge itself spontaneously whenever the disturbance in its equilibrium attains a certain intensity. If the movement of the machine be uniform, and other conditions remain the same, the discharge will take place at regular intervals.

in the earlier months of pregnancy; and at last this irritability seems to reach its acme, in virtue of the nutritive changes which have been progressively taking place in it, and to discharge itself in one powerful effort. Certain preparatory changes are known to be taking place in the Uterus itself, during the last two or three weeks of gestation; for its upper part contracts more closely around its contents, as if it were bracing itself up for the coming encounter; whilst there is a greater disposition to relaxation of its lower part, as also in the soft parts surrounding the orifice of the pelvis, so that the whole mass descends. It is well known that there is far less aptitude for dilatation in the os uteri before this change has taken place, so that premature labours are frequently rendered very difficult and tedious by the resistance which the fœtus encounters from the soft parts, notwithstanding that its smaller size enables it to pass more readily through the pelvic canal.—That the parturient effort, however, is not solely dependent upon the state of development of the uterus, appears from several considerations: and, in the first place, from the very curious fact that, in cases of extra-uterine fœtation, contractions resembling those of labour take place in its walls. In fact, what may be termed the *maturation* not merely of the Uterus, but also of its Embryonic contents—a condition analogous to that which precedes the dropping of ripe fruit, and which is acquired by the completion of the developmental process—appears to have more influence in determining the normal parturient effort, than any other cause which can be assigned. The Placenta of the fully-developed fœtus, indeed, is somewhat in the condition of the footstalk of a ripening fruit; that is, having attained its full evolution as an organ of temporary function, its connection tends to become dissevered in virtue of the further changes which take place in itself, quite irrespectively of any external agency.* This is very strikingly evinced by the fact, that when the uterus contains two fœtuses, and one of them is expelled—either in consequence of impeded development or disease in itself, or because it has attained its own full term of development (as in cases of superfœtation, § 724)—the other, if its development at this period is far from complete, is often retained, and goes on to its full term, *its* placenta not being detached in the first parturient effort, because it was not then prepared for the separation. It is obvious that this view affords a rational explanation of the occurrence of uterine action in cases of extra-uterine fœtation; for, if the condition of the placental attachment furnish its exciting cause, it will do so equally, whether the placenta be attached to the lining of the uterus, or to that of the Fallopian tube, or to any other organ. It is an additional indication that the immediate stimulus to the parturient effort of the uterus is given by some change in the condition of its fœtal connections, that the term of gestation seems capable of being prolonged by peculiarities in the constitution or rate of development of the fœtus, which are derived from the male parent; for it was ascertained by the late Earl Spencer,† that of 75 cows in calf by a particular bull, the average period was 288½ days, instead of 280; none of these having gone less than 281 days, and two-fifths of them having exceeded 289 days.

722. Various states of the constitution, especially that which is designated

* Such a change may be easily verified in the Placenta of many of the lower animals, such as that of the Cat, in which the fœtal and maternal portions remain more distinct from each other than they do in the Human female; for these become far more easily separable as the period of parturition draws near than they are at any previous time. De Sinéty ("Arch. de Physiol.," 1876, p. 342) states that it is impossible to ascribe the detachment of the placenta to the fatty degeneration of the decidua, for the quantity of fat they contain is in point of fact extremely minute.

† See Dr. J. C. Hall, in "Medical Gazette," May 6, 1842.

as 'irritability,' may induce the occurrence of the parturient effort at an earlier period; and this constitutes Premature Delivery or Abortion, according as the child is or is not *viable* (§ 723). There are some women in whom this regularly happens at a certain month, so that it seems to be an action natural to them; but it should always be prevented, if possible, being injurious alike to the mother and to the child; and this prevention is to be attempted by rest and tranquillity of mind and body, and by a careful avoidance of all the exciting causes which may produce uterine contractions by their operation on the Nervous system (§ 729). Among the causes of Abortion, however, the death of the fœtus, or an abnormal state of the placental structure, is one of the most common; and thus we have another very distinct proof of the influence which the state of the *contents* of the uterus has on the induction of the parturient effort.

723. The question of the *extreme limits* of the period of Gestation, is one of great importance both to the Practitioner and to the Medical Jurist.—In regard to the *shortest* period at which Gestation may terminate, consistently with the *viability* of the Child, there is still a great degree of uncertainty. Most practitioners are of opinion that it is next to impossible for a fœtus to live and grow to maturity, which has not nearly completed its seventh month; but it is unquestionable that infants born at a much earlier period have lived for some months, or even to adult age. It is rare in such cases, however, that the date of conception can be fixed with sufficient precision to enable a definite statement to be given. Of the importance of the question, a case which some time since occurred in Scotland affords sufficient proof. A vast amount of contradictory evidence was adduced on this trial; but, on the general rule of accepting positive in preference to negative testimony, it seems that we ought to consider it possible that a child may live for some months, which has been born at the conclusion of 24 weeks of gestation. In the case in question, the Presbytery decided in favour of the legitimacy of an infant born alive, within 25 weeks after marriage.* A like uncertainty exists

* "Report of Proceedings against the Rev. Fergus Jardine," Edinburgh, 1839. Several instances are on record of the survival of infants born at a very early period, thus:—A very interesting case is on record ("Edinb. Med. and Surg. Journal," vol. xi.) in which the mother (who had borne five children) was confident that her period of gestation was less than 19 weeks; the facts stated respecting the development of the child are necessarily very imperfect, as it was important to avoid exposing his body, in order that his temperature might be kept up; but three weeks after his birth he was only 13 inches in length, and his weight was no more than 29 oz. At that time, according to the calculation of the mother, he might be regarded as corresponding with an infant of 22 weeks or five months; but the length and weight were greater than is usual at that period, indicating that he was probably born at about the 25th week. It is an interesting feature in this case, that the calorific power of the infant was so low, that artificial heat was constantly needed to sustain it; but that under the influence of the heat of the fire he evidently became weaker, whilst the warmth of a person in bed rendered him lively and comparatively strong. During the first week it was extremely difficult to get him to swallow; and it was nearly a month before he could suck. At the time of the report he was four months old, and his health appeared very good.—Another case of very early viability has been more recently put on record by Mr. Dodd ("Provincial Medical and Surgical Journal," vol. ii. p. 474): in this, as in the former instance, the determination of the child's age rests chiefly on the opinion of the mother; but there appears no reason for suspecting any fallacy. The child seems to have been born at the 26th or 27th week of gestation, and having been placed under judicious management, it has thriven well.—One of the most satisfactory cases on record is that detailed by Dr. Outrepont, Professor of Obstetrics at Wurtzburg (Henke's "Zeitschrift," Band vi.), and stated by Dr. Christison in his evidence on the case first alluded to. The evidence is as complete as it is possible to be in any case of the kind; being derived not only from the date assigned by the mother to her conception, but also from the structure and history of the child. The gestation could have lasted only 27 weeks, and was very probably less. The length of the child was 13½ inches, and its weight was 24 oz. Its development was altogether slow; and at the age of eleven years the child

with regard to the degree of *protraction* of which the ordinary duration of Gestation is capable.—Many obstetric practitioners, whose experience should give much weight to their opinion, maintain that the regular period of 40 weeks is never extended by more than two or three days; whilst, on the other hand, there are numerous cases on record, which, if testimony is to be believed at all (and in many of these the character and circumstances of the parties place them above suspicion), furnish ample evidence, that Gestation may be prolonged for at least three weeks beyond the regular term.* In one case, indeed, recorded by Liegard,† pregnancy was believed to have lasted 330 days. The English law fixes no precise limit; and the decisions which have been given in our courts, when questions of this kind have been raised, have been mostly formed upon the collateral circumstances. The law of France provides that the legitimacy of a child born within 300 days after the death or departure of the husband shall not be questioned; and a child born after more than 300 days is not declared a bastard, but its legitimacy may be contested. By the Scotch law, a child is not declared a bastard, unless born after the tenth month from the death or departure of the husband.—Very important evidence on this subject is afforded by investigations on the lower animals, which are free from many sources of fallacy that attend human testimony. The observations of Tessier, which were continued during a period of forty years, with every precaution against inaccuracy, have furnished a body of results which seems quite decisive. In the Cow, the ordinary period of gestation is about the same as in the Human female; but out of 557 individuals, no less than 20 calved beyond the 298th day, and of these, some went on to the 321st, making an excess of nearly six weeks, or about *one-seventh* of the entire period. Of 447 Mares, whose natural period of gestation is about 335 days, 42 foaled between the 359th and 419th days, the greatest protraction being thus 84 days, or just *one-fourth* of the usual term. Of 912 Sheep, whose natural period is about 151 days, 96 yeaned beyond the 153rd day; and of these, 7 went on until the 157th day, making an excess of 6 days. Of 161 Rabbits, whose natural period is about 30 days, no fewer than 25 littered between the 32nd and the 35th; the greatest protraction was here *one-sixth* of the whole period, and the proportion in which there was a manifest prolongation was also nearly one-sixth of the total number of individuals. In the incubation of the common Hen, the duration of which must be entirely determined by the rate of embryonic development, Tessier found that there was not unfrequently a prolongation to the amount of three days, or *one-seventh* of the whole period.—In regard to Cows, the observations of Tessier have been confirmed by those of Earl Spencer, who has published‡ a table of the period of gestation as observed in

seemed no more advanced in body or mind than most other boys of seven years old. In this last point there is a very striking correspondence with the results of other observations upon premature children, made at an earlier age.—A very remarkable case has also been recorded by Dr. Barker, of Dumfries ("Medical Times," Sept. 7 and Oct. 12, 1850) in which the child is affirmed to have been born on the 158th day of gestation, or in the middle of the *twenty-third* week after intercourse. Its size, weight, and grade of development were conformable to the asserted period: for it weighed only 16 oz., and measured 11 inches; it had only rudimentary nails, and scarcely any hair except a little of reddish colour on the back of the head; the eyelids were closed, and did not open until the second day; the skin was shrivelled. When born it was wrapped up in a box and placed before the fire. The child did not suck properly until after the lapse of a month, and did not walk until she was nineteen months old. Three years and a half afterwards this child was in a thriving state, and very healthy but of small make; she then weighed 29½ lbs.

* A good collection of such cases will be found in Dr. Montgomery's excellent work on the "Signs of Pregnancy," and in Dr. A. Taylor's "Medical Jurisprudence."

† "Gaz. des Hôpitaux," 1859. ‡ "Journal of the English Agricultural Society," 1839.

764 individuals; he considers the average period to be 284 or 285 days; but no fewer than 310 calved after the 285th day; and of these, 3 went on to the 306th day, and 1 to the 313th. It is curious that among the calves born between the 290th and 300th days, there was a decided preponderance of males—these being 74, to 32 females; whilst all of those born after the 300th day were females. The additional series of observations subsequently made by Earl Spencer, in regard to the constant protraction of the period in 75 cows in calf by a particular bull, has been already noticed (§ 721).—Another series of observations has been published by Mr. C. N. Bement, of Albany, U.S.,* who has recorded the period of gestation of 62 cows. The longest period was 336 days; the shortest, 213 days. The average period for male calves was 288 days; and for females 282 days.—On the whole it may be considered, that in regard to the Human female, the French law is a very reasonable one; there being quite sufficent analogical evidence to support the assertions of females of good character, having no motive to deceive, which lead to the conclusion that a protraction of at least four weeks is quite possible, and that a protraction of six weeks is scarcely to be denied.†

724. There is another question regarding the function of the Female in the Reproductive act which is of great interest in a scientific point of view, and which may become of importance in Juridical inquiries—namely, the possibility of *Superfecundation*—that is, of two distinct conceptions at an interval of greater or less duration; so that two fœtuses of different ages, the offspring perhaps of different parents, may exist in the uterus at the same time. —The simplest case of Superfecundation is that in which a female has intercourse on the same day with two males of different complexions, and bears twins at the full time; the two infants resembling the two parents respectively. Thus, in the southern states of America, a black woman may bear at the same time a black and a mulatto child; the former being the offspring of her black husband, and the latter of her white paramour. The converse has occasionally, though less frequently occurred; a white woman having at the same time a white and a mulatto child. There is no difficulty in accounting for such facts, when it is remembered that nothing has occurred to prevent the uterus and the ovaria from being as ready for the second conception as for the first; since the decidua does not at first form a closed sac, as was formerly supposed, and consequently neither the orifice of the uterus nor of the Fallopian tubes is yet closed up; and, at the time when one ovum is matured for fecundation, there are usually more in nearly the same condition. Many such cases of alleged superfecundation are explicable upon the theory of atavism (§ 725).—But it is not easy thus to account for the birth of two children, which constitutes *Superfœtation*, each apparently mature, at an interval of five or six months; since it might have been supposed that the uterus was so completely occupied with the first ovum, as not to allow of the transmission of the seminal fluid necessary for the fecundation of the second. In cases where two children have been *produced* at the same time, one of which was fully formed, whilst the other was small and seemingly premature, there is no occasion whatever to imagine that the two were *conceived* at different periods; since the smaller fœtus may have been 'blighted,' and its development retarded, as not unfrequently happens in other cases. Nor is it

* "American Journal of the Medical Sciences," October, 1845.

† See especially two cases, 183 and 184, detailed by Dr. Murphy in his "Report of the Obstetric Practice of University College Hospital" for 1844; and another case published by him in the "Medical Gazette" for 1849, vol. xlviii. p. 683.

necessary to infer the occurrence of superfœtation in every case in which a living child has been produced a month or two after the birth of another; since the latter may have been somewhat premature, whilst the former has been carried to the full term. But such a difference can scarcely be, at the most, more than 2½ or 3 months;* and there are several cases now on record in which the interval was from 110 to 170 days, whilst neither of the children presented any indication of being otherwise than mature. In such cases, it is possible that there may have been a double uterus, the ova in the two portions of which may or may not have been impregnated on the same day.†

725. Whatever be the precise nature and history of the Fecundating process, there can be no doubt that the properties of the Germ depend upon conditions, both material and dynamical, supplied by *both* Parents. This is most obviously shown by the *fusion* of the characters of the parents, which is exhibited by *hybrids* between distinct species or strongly-marked varieties among the lower animals, such as the Horse and Ass, the Lion and Tiger, or the various breeds of Dogs; or in the offspring of parents belonging to two strongly-contrasted Races of Men, such as the European on the one hand, and the Negro or American Indian on the other.—It has long been a prevalent idea that certain parts of the organism of the offspring are derived from the male, and certain other parts from the female parent; and although no universal rule can be laid down upon this point, yet the independent observations which have been made by numerous practical 'breeders' of domestic animals (both mammals and birds), seem to establish that such a *tendency* has a real existence; the characters of the *Animal* portion of the fabric being especially (but not exclusively) derived from the *male* parent, and those of the *Organic* apparatus being in like manner derived from the *female* parent. The former will be chiefly manifested in the external appearance, in the general configuration of the head and limbs, in the organs of the senses (including the skin), and in the locomotive apparatus; whilst the latter show themselves in the size of the body (which is primarily determined by the development of the viscera contained in the trunk), and in the mode in which the vital functions are performed. Thus the *mule*, which is the produce of the male ass and the mare, is essentially a *modified ass*, having the general configuration of its sire (slightly varied by equine peculiarities), but having the rounder trunk and larger size of its dam; on the other hand, the *hinny*, which is the offspring of the stallion and the she-ass, is essentially a *modified horse*, having the general configuration of the horse (though with a slight admixture of asinine features), but being a much smaller animal than its sire, and thus approaching its dam in size, as well as in the comparative narrowness of its trunk. The influence of the female on the general 'constitution,' and especially on the fattening, milking, and breeding qualities of the offspring, is asserted to be proved by the history of several races of sheep and cattle, which have been most distinguished in these respects.§—But however *general* this rule may prove to be as regards

* For an interesting case of superfœtation, where the difference in the age of the two fœtuses was about three months, see a Report made by Drs. Harley and Tanner to the Obstetrical Society, "Lancet," vol. ii. 1862.

† See the Article 'Superfœtation,' in Dr. Beck's "Elements of Medical Jurisprudence," and R. B. Schultze in the "Jenaische Zeits.," Band ii. 1865, p. 1; and a Paper by Dr. Bonnar ("Edinburgh Med. Journal," Jan. 1865), for cases in which children succeeded each other very rapidly.

‡ For an excellent account of all the questions relating to Hybrids, reference may be made to Darwin's "Animals and Plants under Domestication."

§ See Walker 'On Intermarriage;' Orton on 'The Physiology of Breeding,' in the "Newcastle Chronicle," March 10, 1854; and Dr. Alex. Harvey 'On the Relative Influence of the Male and Female Parents in the Reproduction of the Animal Species,' in "Edinb. Monthly

the lower animals, it is by no means *universal;* for instances are by no means unfrequent, in which the multiple progeny of one conception divide between them the characters of the parents in very different modes. Thus, in a case in which a Setter-bitch, having been 'lined' by a Pointer, bore three pups, two of these pups seemed exclusively to resemble the father, appearing to be perfect Pointers in configuration, and growing-up with the habits of that race; whilst the third seemed equally to resemble its mother, being apparently a true Setter both in structure and instinct. Yet notwithstanding this apparent restriction, it subsequently appeared that the pointer-pups must have had something of the setter in their constitution, and the setter-pup something of the pointer. For one of the Pointer-pups (a male) having been matched at the proper age with a pointer-bitch of pure breed, one of the pups borne by the latter was a *true setter*, exactly resembling its paternal grandmother, and another was *setter-marked;* and the Setter-pup (a female) having been lined by a Setter-dog of pure breed, there were among its litter of pups two *pointers* resembling their maternal grandfather.—The same variety presents itself to even a greater degree in the human species. For in almost every large family (and sometimes even where there are no more than two children*), it will be observed that the likeness to the father predominates in some of the children, and the resemblance to the mother in others. Still it is rare to meet with instances in which *some* distinctive traits of *both* parents may not be traced in the offspring; these traits often showing themselves, in peculiarities of manner and gesture, in tendencies of thought or feeling, in proneness to particular constitutional disorders, &c., even where there is no personal resemblance, and where there has been no possibility that these peculiarities should have been gained by imitation. And even when they are overborne, as it were, in the immediate progeny, by the stronger influence derived from the other side, they will often reappear in a subsequent generation (as in the case just cited), constituting the phenomena known as *Atavism* or Reversion.†

726. The influence of both Parents on the constitution of the Offspring is strikingly manifested, not merely in the admixture of their characters normally displayed by the latter, but also in the tendency to *hereditary transmission* of perverted modes of functional activity which may have been habitual to either. The diseases which are usually considered to be most prone thus to reappear in successive generations are Scrofula, Gout, Syphilis, and Insanity; but it can scarcely be doubted that many others might be added to this list.‡ The predisposition may have been *congenital* on the part of the parents, or it may have been *acquired* by themselves, as in the case of Epilepsy transmitted by guinea-pigs in whom the sciatic nerve has been divided, to their young; and in no case is this more obvious than in the influence of Alcoholic excesses on the part of one or both parents, in producing Idiocy, a predisposition to Insanity, or weakness and instability of Mind, in the children,

Journ.," Aug. 1854; and especially Darwin "On the Variation of Species under Domestication," 1868.

* One of the most remarkable cases of this kind known to the Author, is that of two Sisters who seem to resemble each other in no one point of configuration or mental character; but of whom one bears a most striking resemblance, both in person and in mind, to her Father; whilst the other no less strikingly resembles her Mother. The only peculiarities which at all indicate their relationship, are a gouty diathesis which they both inherit from their father, and an idiosyncrasy in regard to opium, of which neither is able to take even a small dose (in any form whatever) without violent vomiting.

† Darwin, "Animals and Plants under Domestication," vol. ii. chap. xiii.

‡ See the very interesting and suggestive chapter 'On Hereditary Disease,' in Sir H. Holland's "Medical Notes and Reflections."

this being especially the case where both parents have transgressed. Thus, out of 359 Idiots, the condition of whose progenitors could be ascertained, it was found that no fewer than 99 were the children of absolute drunkards; and there was reason to believe that a large proportion of the parents of the remainder were more or less intemperate, only about a quarter of the whole number of idiots having been found to be the children of parents who were known to be temperate.* And it is perfectly well known to those who are conversant with Insanity, that, of all the 'predisposing causes' of that disorder, habits of intemperance on the part of either or both parents are among the most frequent.—The intensification which almost any kind of perversion of Nutrition derives from being common to *both* parents, is most remarkably evinced by the lamentable results which too frequently accrue from the marriage of individuals nearly related to each other and partaking of the same 'taint.' Such results must have fallen within the knowledge of almost every one possessing an extended field of observation; but they are brought out with fearful vividness by the unerring test of properly collected Statistics. For out of the 359 idiots just referred to, 17 were *known* to have been the children of parents nearly related by blood; and this relationship was *suspected* to have existed in several other cases in which positive information could not be obtained. On examining into the history of the 17 families to which these individuals belonged, it was found that they had consisted, in all, of 95 children; that of these no fewer than 44 were idiotic, 12 others were scrofulous and puny, 1 was deaf, and 1 was a dwarf. In some of these families all the children were either idiotic or very scrofulous and puny; in one family of 8 children, 5 were idiotic.†—But it does not seem requisite for the production of very imperfect offspring from the intermarriage of near relations, that any decided 'taint' should exist in the parents; for the Author's own observations and inquiries lead him to conclude that the same danger results when there is any strong personal or mental 'idiosyncrasy,' such as is often seen to run through the members (both male and female) of a particular family, causing them to be at once recognized as belonging to it,

* See Dr. Howe's "Report on Idiocy to the Legislature of Massachusetts," 1848.

† See Dr. Howe's Report, p. 90. An Abstract of this Report is given in the "Amer. Journ. of Med. Sci.," April, 1849.—The following works may also be referred to as containing information upon the important subject of the effects upon the offspring of marriages of consanguinity:—M. Boudin in the "Annales d'Hygiène," vol. xviii. pp. 6–82, who observes that the deaf-mutes of consanguineous origin are from twelve to fifteen times as numerous as they would be if the infirmity were equally distributed among the offspring of consanguineous and other marriages; Dr. Bemiss in the "Journal of Psychological Medicine" for 1857, p. 368, who supplies facts and arguments against such marriages; Dr. Mitchell in the "Edinb. Med. Journ." for 1862, p. 872, who considers idiocy to be an especially frequent consequence of the marriage of blood-relations, and agrees with M. Boudin in regard to the frequency of deaf-mutism in the offspring; M. Cadiot in the "Comptes Rendus," vol. ii. 1863, p. 978; M. Angelon in idem, vol. i. 1864, p. 166; and Dr. E. Dally in the "Anthropological Review" for May, 1864. See also "Essays on Physiological Subjects," by G. W. Child, pp. 1–55, 1869; Herbert Spencer's "Principles of Biology," vol. i. pp. 281–283, and Dr. Galton "On the Influence of Heredity." Amongst the Editor's own immediate relations there have been five marriages between first cousins, from which have proceeded thirty-three children; of these, eight have died, one from teething, two from croup, and one from hooping-cough (all injudiciously fed), one from accident, one from cyanosis, and two from well-marked scrofulous disease; the last two occurred in the same family, and were the only offspring of an extremely obese father and a highly scrofulous mother. The surviving children are of unusually healthy and fine growth. See also a Leader in "Lancet," 1870, vol. ii. p. 898. The Editor, therefore, from these and other observations, fully accords with the observations of Dr. G. W. Child in the "Medico-Chir. Review" for 1862, vol. i. p. 461, who, in criticizing Dr. Bemiss's Essay, remarks that the marriages of blood-relations have no tendency, *per se*, to produce degeneration of race, though they have a tendency to strengthen and develop in the offspring individual peculiarities of the parents, both mental and physical, whether morbid or otherwise.

by those who have been familiar with other members.* Dr. Darwin† has also shown that long continued and close interbreeding between the nearest relations diminishes the constitutional vigour, size, and fertility of the offspring; and occasionally leads to malformations, but not necessarily to general deterioration of form and structure. This liability probably does not exist to nearly the same degree, where the parents, although nearly related, differ widely in physical and in psychical characters, through the predominance of elements which have been introduced by *their* non-related parents; as, for example, when a man strongly resembles his *father* rather than his mother, marries the daughter of his *mother's* brother, who, on her part, resembles her own *mother* rather than her father. But the case previously cited (§ 725) gives warning that even here the 'family idiosyncrasy' may exist in a powerful degree, though in a latent form, and may seriously affect the constitution of the offspring. It is quite as common to meet with Atavism in the transmission of hereditary disease as in the reproduction of 'family likeness.'

727. Attention has also been directed to a very curious class of phenomena, which show that where the mother has previously borne offspring, the influence of *its* father may be impressed on her progeny afterwards begotten by a different parent: as in the well-known case of the transmission of Quagga-marks to a succession of colts, both of whose parents were of the species Horse, the mare having been once impregnated by a Quagga male;‡ and in the not unfrequent occurrence of a similar phenomenon in the Human species, as when a widow who marries a second time bears children strongly resembling her first husband. Some of these cases appear referable to the strong mental impression left by the first male parent upon the female; but there are others which seem to render it more likely that the blood of the female has imbibed from that of the fœtus, through the placental circulation, some of the attributes which the latter has derived from its male parent; and that the female may communicate these, with those proper to herself, to the subsequent offspring of a different male parentage.§—This idea is borne out by a great number of important facts; and it serves to explain the circumstance well known to practitioners, that secondary syphilis will often appear in a female during gestation or after parturition, who has never had primary symptoms, whilst the father of the child shows no recent syphilitic disorder. For if *he* have communicated a syphilitic taint to the fœtus, the mother may become inoculated with it through her offspring in the manner just described. As this is a point of great practical importance, it may be hoped that those who have the opportunity of bringing observation to bear upon it will not omit to do so.

728. There seems good reason to believe, moreover, that the attributes of the Germ are in great degree dependent, not merely upon the *habitual* conditions of the Parents which have furnished its original components, but even upon the condition in which those parents may be at the time of sexual congress. Of this we have a remarkable proof in the phenomenon well known to

* A most lamentable instance of this kind, which happened some years ago in a family well known to the Author, was the occasion of his first directing his attention specially to this point. Two first-cousins, possessing a strong 'family idiosyncrasy,' but no definite 'taint,' having married, four children were born, each of which was distinguished by some marked effect of organization or perversion of function, one being deaf and dumb, another scrofulous, a third idiotic, and a fourth epileptic.

† Op. cit. vol. ii. p. 159, ed. Murray, 1875. ‡ "Philosophical Transactions," 1832.

§ See an interesting discussion of this question, by Dr. Alex. Harvey, in the "Edinb. Monthly Journ.," Oct. 1849, and Oct. and Nov. 1850; and in his pamphlet "On a Remarkable Effect of Cross-breeding," Edinb. 1851.

breeders of animals, that a strong mental impression made upon the female by a particular male, will give the offspring a resemblance to him, even though she has had no sexual intercourse with him;* a circumstance for which there is no difficulty in accounting, on the hypothesis already put forth regarding the dynamical relation of mental states to the Organic processes (Chap. XVII.). On the whole, then, we seem entitled to conclude, that the attributes of the embryo will be influenced in a most important degree by the entire condition (as relates both to the organic and the psychical life) of both parents at the time of the sexual congress; and it is probably on account of the perpetual changes taking place in the bodily and mental state of each individual (his condition at any one time being the general resultant of all those changes), that we almost constantly witness marked differences between children born at successive intervals, however strong may be the 'family likeness' among them; whilst the resemblance between twins is almost invariably much closer.†

729. When it is borne in mind that, during the entire period of gestation, the Embryo is deriving its nutriment exclusively from the blood of the Mother, and that the condition of this fluid in relation to her own processes of Nutrition and Secretion, is subject to a very marked influence from her own mental states (Chap. XVII.), it cannot fairly be thought improbable, that the developmental processes of the Embryo should be powerfully affected by strong Emotional excitement on her part. Among the facts of this class, there is, perhaps, none more striking than that quoted by Dr. A. Combe‡ from Baron Percy, as having occurred after the siege of Landau in 1793. In addition to a violent cannonading, which kept the women for some time in a constant state of alarm, the arsenal blew up with a terrific explosion which few could hear with unshaken nerves. Out of ninety-two children born in that district within a few months afterwards, Baron Percy states that 16 died at the instant of birth; 33 languished for from eight to ten months, and then died; 8 became idiotic, and died before the age of five years; and 2 came into the world with numerous fractures of the bones of the limbs, probably caused by irregular uterine contractions. Here, then, is a total of 59 children out of 92, or within a trifle of 2 out of every 3, actually killed through the medium of the Mother's alarm, and the natural consequences upon her own organization; an experiment (for such it is to the Physiologist) upon too large a scale for its results to be set down as mere 'coincidences.'—No soundly-judging Physiologist of the present day is likely to fall into the popular error of supposing that 'marks' upon the Infant are to be referred to some *transient* though strong impression upon the imagination of the Mother; but there appear to be a sufficient number of facts on record to prove that *habitual* mental conditions on the part of the Mother *may* have influence enough, at an early period of gestation, to produce evident bodily deformity, or peculiar tendencies of the mind. The error of the vulgar notion on this subject lies in supposing that *a sudden fright, speedily forgotten*, can exert such a continual influence on the nutrition of the Embryo, as to occasion any personal peculiarity.§ The view here stated is one which ought to have great

* See Harvey, loc. cit.

† Where twins are very unlike one another, it will usually be found that the dissimilarity is due to the predominance of the characters of the father in one, and of those of the mother in the other; as in the case of the Pointer and Setter previously cited (§ 725).

‡ "On the Management of Infancy," p. 76.

§ For some valuable observations on this subject, see Montgomery "On the Signs of Pregnancy."—Numerous cases were recorded a few years since (especially in the "Lancet" and "Provincial Medical Journal") in which malformations in the Infant appeared distinctly

weight, in making manifest the importance of careful management of the health of the Mother, both corporeal and mental, during the period of pregnancy; since the ultimate constitution of the offspring so much depends upon the influences then operating upon its most impressible structure.

4. *Development of the Embryo.**

730. The history of the evolution of the Germ, from its first appearance as *a single cell* lying in the midst of the yolk, to the time when it presents the form and structure characteristic of its parent species, and is capable of maintaining an independent existence—including the details of the progressive development of each separate organ, from its first appearance as an aggregation of simple cells formed by the duplicative subdivision of the primordial vesicle, to that stage of completeness in which it is able to bear a part in the vital economy of the new being—and embracing, also, the succession of changes in the provisions for the nutrition of the embryo in the successive phases of its existence, and the adaptations of its general organization to each respectively—constitutes one of the most interesting departments of Physiological Science, and one which has of late years received a peculiar degree of attention. It is a branch of the inquiry, however, which has, and seems likely to have, less *practical* bearing than any other; for neither as regards the preservation of the body in health, nor its restoration from disease, is it easy to see what direct benefit the most exact knowledge of Embryonic Development is likely to afford. The chief subject on which it throws light, is that of Congenital Malformations and Deficiencies; many of which are now distinctly traceable to *arrest* or *irregularity* of the developmental processes; some of them, indeed, to *excess*. For these reasons, the topic before us will be passed over much more lightly in the present Treatise, than its scientific importance might seem to demand; and all that will be here attempted, will be a mere sketch of the mode in which the evolution of the germ takes place, this being followed in the first instance as a whole, whilst its principal organs will be afterwards separately considered as they successively present themselves.—This sketch, however, will serve to convey an idea of the nature of the process, and to illustrate its conformity in Man to that great law of progress *from the general to the special*, which is equally manifested in the development of every other organized being.

731. When we first discern the primordial cell which is to evolve itself into the Animal organism, we can trace nothing that essentially distinguishes it from that which might give origin to *any* other form of organic structure; its condition, in fact, being alike in all, and permanently represented by the humblest single-celled Plants and Animals. The earliest stage of its development consists in simple multiplication by 'duplicative subdivision' of its contents, so that a mass of cell-like bodies comes to be produced, amidst the several components of which no difference can be traced; and this also finds its parallel among the simpler organisms of both kingdoms. Soon, however, this *homogeneous* condition gives rise to a *heterogeneous* one; the further

traceable to strong impressions made on the mind of the Mother some months previously to parturition; these impressions having been persistent during the remaining period of pregnancy, and giving rise to a full expectation on the part of the Mother that the child would be affected in the particular manner which actually occurred. Of one very striking case of this kind the Author is personally cognizant, it having occurred in a family of a near connexion of his own.

* The Anatomy of the Human Embryo may be studied in the work of Wilhelm His, which is at present being issued by Vogel of Leipzig, 1880.

changes which different parts of this mass undergo, not being of the same uniform character, so that a marking out of *organs*, or instrumental parts adapted for different purposes in the economy, begins to be discernible. A marked divergence, as was shown by Reichert, occurs, however, at a very early period, according to whether the whole contents of the ovum undergo segmentation, and are directly converted into the growing embryo, or whether only a portion is thus segmented, the remainder forming a bag over which vessels are developed, effecting the absorption of its contents, and thus enabling it indirectly to participate in the process of development. The former kind of egg, consists, therefore, altogether of germ yolk; the latter of a small germ yolk,* and a large food yolk.† Ova in which the former arrangement holds are termed *holoblastic*, and are represented by Mammals generally, Batrachia, Cyclostomata, and Amphioxus amongst the Vertebrata, and by the simpler forms of Crustacea and Arachnida, the Annelida, lower Mollusca, Entozoa, and Echinodermata amongst the Invertebrata. The ova in which the latter arrangement holds, are termed *meroblastic*, and are represented by Birds, Reptiles, Fish, with the exception of the Cyclostomes amongst the Vertebrata, and by the Cephalopoda, and higher orders of Crustacea and Arachnida amongst the Invertebrata. In the fowl, according to His (loc. cit. p. 39), the whole of the nervous system, the whole of the muscular system (both striated and unstriated), the true epithelial structures and the glands proceed from the development of the morphological elements of the cicatricula, whilst the blood and the connective tissues, together with the endothelial lining of the blood-vessels, proceed from the so-called white yolk. The organs whose distinctness first becomes apparent, are not (for the most part) those which we trace in the completed structure, but have a merely temporary character; being evolved either as a sort of scaffolding or frame-work for the building up of the more permanent parts, or with a view to the nutrition of the embryo during the evolution of these. Although the first indications of heterogeneousness in the general mass are of nearly the same kind in all animals—consisting in the formation of a *blastodermic membrane* (composed, however, of nothing else than layers of cells) upon its exterior, which serves as a sort of temporary stomach, whilst a large part of the included mass undergoes liquefaction, and serves as the nutrient material for the tissues which are to be evolved from it—yet indications are very speedily manifested, of the *primary division* of the Animal Kingdom of which the new being is a member. In the case of the Human embryo, as in that of all Vertebrate animals, the first outline of the permanent organization is shown in the 'primitive trace,' which fades away, and above which appears the medullary groove, marking out the line of the vertebral column (Plate II., Fig. 11); and in this we very soon discern the foundations of the separate vertebræ (Fig. 333, *pr*). But there is nothing at this period to distinguish the germ of Man from that of *any other* Vertebrate animal, this early part of the developmental process being carried on upon the same plan in every member of that sub-kingdom; and it is not until we meet with indications of one of the plans which are peculiar to the respective classes of that sub-kingdom, that we can discover whether the germ in course of evolution is to become a Mammal, Bird, Reptile, or Fish. So, even when it has been recognized as belonging to the Mammalian class, there is at first nothing to distinguish it from that of any other Mammal; and it is only with the advance of the developmental process that indications successively present themselves, which enable us to distinguish, one after another, the characters

* The *Protoplasm* of Van Beneden. † The *Deutoplasm* of the same author.

of the order, the family, the genus, the species, the variety, the sex, and the individual—*the more special features progressively evolving themselves out of the more general*, which is the expression of the law of development common to all Organized beings.

732. With this progressive alteration in the condition of the embryo itself, a very remarkable series of alterations is proceeding, *pari passu*, in the mode in which it is supplied with nutrient material, and in the provisions for the aëration of its circulating fluid.—The first evolution of the germ takes place entirely at the expense of the *yolk:* of which, however, the store contained in the Mammalian ovum is very small. The whole of this is very speedily incorporated in the substance of the germ, by the peculiar process to be presently described; and there is no residual store of 'food-yolk,' such as that which, in the Bird, serves for the nutrition of the embryo during the whole remainder of the developmental process, by being gradually absorbed into the substance of the blastodermic membrane, and there converted into blood. The Mammalian ovum, however, from the time it reaches the Uterus, is furnished with a new supply of nourishment, in the fluid secreted by the Decidual membrane; and, for the absorption of this, it is particularly adapted by the villosities which develop themselves from its own external envelope (§ 711). These, at first entirely destitute of blood-vessels, are subsequently penetrated, at a certain part of the surface, by the fœtal capillaries brought to them by an organ, the *Allantois*, which is developed in Birds as the temporary instrument of respiration; and thus is originated the *fœtal* portion of the Placenta, of whose formation an account has already been given (§§ 712, 713). From the time that this organ is completed, up to the birth of the Infant, the embryo draws its nutrient materials direct from the maternal blood, though not receiving that blood *as such* into its own organism, since there is no direct communication between the blood of the fœtus and that of the mother; and it is through the same medium that the aëration of its own blood is effected, its pulmonary apparatus being as yet inoperative. Its circulating system, arranged in accordance with these requirements, presents many peculiarities which mark its fœtal character; and the alteration in the course of the blood, which takes place as soon as the respiratory organs come into play, constitutes the essential difference between intra-uterine and extra-uterine life. If, as sometimes happens, the lungs of the new-born infant expand but imperfectly or scarcely at all, the circulation continues to be carried on in a greater or less degree upon its intra-uterine plan; and this, when the placenta is no longer capable of supplying the needed aëration, is incompatible with the persistence of life.

733. The early stages of the development of the Embryo in Vertebrata are much better known in the Bird than in the Mammal, on account of the facilities which the eggs of these animals offer for examination, and it will be expedient, therefore, to describe the course of events in them: noting the principal differences that have been observed in the process as it occurs in the higher class.* A newly-laid hen's egg consists of a shell (Fig. 326, *s*),

* In the following account, Foster and Balfour's "Elements of Embryology" has been taken as a guide, and to this excellent work the student is referred for details that considerations of space preclude from being here inserted; but other works and researches which may be studied are those of Rathke, "On the Development of the Snake," 1839, and of the Tortoise, 1848,—of Kölliker (Müller's "Archiv," 1843, p. 68) and Bagge ("De Evolut. Strongyli et Ascarid., Diss. Inaug.," 1841) on the ova of *Entozoa*,—Kölliker's "Entwickelungsgeschichte des Menschens," 1879,—those of v. Baer, "On the Development of the Fish," 1835,—those of Newport ("Philos. Transact.," 1851) and Dugès ("Récherches sur les Batraciens," 1835) on the ova of *Batrachia*,—those of Bischoff ("Entwickelungsgeschichte des Hundes-

composed of an organic basis impregnated with calcic salts, and perforated by vertical canals, through which an interchange of gases can take place. The shell is lined by two layers of membrane (Fig. 326, *s m*, *i s m*), which early separate from each other at the broad end to form the air-chamber. Beneath the shell membrane is the white of the egg, or albumen (Fig. 326, *w*); and stretching from near the two extremities of the egg to the opposite surfaces of the yolk, are two twisted portions of rather firmer albumen, termed the *chalazæ* (*ch*, *l*), which perhaps serve to keep the yolk in position. The yolk is enclosed in the *vitelline membrane* (*vt*), and by far the largest portion of it is composed of *yellow yolk* (*yy*), which consists of spheres, never containing a nucleus, but filled with minute, highly refractile granules. The yellow yolk is surrounded by a thin layer of a lighter-coloured yolk, the *white yolk* (*wy*), which dipping into it at one point, forms a flask-shaped mass in its interior. The white yolk also forms a series of concentric layers (*halones*) in the substance of the yellow yolk. It is composed of spherules, for the most part smaller than those of the yellow yolk, with a highly refractive nucleus-like body in the interior of each, and of larger spheres, each of which contains a number of spherules similar to the smaller spherules; it presents also some

vacuoles in the region of the cicatricula. At the point where the white yolk dips into the yellow yolk is a depression, which is occupied by a small white disk, about the sixth of an inch in diameter, termed the *blastoderm* or *cicatricula* (*bl*). The disk is always uppermost when the egg is opened from the side, in consequence of the lighter specific gravity of this part of the vitellus. A typical cicatricula presents an outer white rim, or *area opaca*, a circular transparent area, or *area pellucida*, and a more or less well-marked central opacity. The area opaca and central opacity appear to be due to the disposition of the white yolk beneath the blastoderm, whilst in the part corresponding to the area pellucida, the blastoderm is separated from the white yolk by a space, filled with a little fluid. Imbedded in the protoplasm of the germinal disk is a globular or ellipsoidal highly refractile body, termed the *germinal vesicle;* in the interior of which, again, is a small body, the *germinal spot.*

734. The ovum of the Mammal differs from that of the bird in not presenting the same differentiation into white and yellow yolk and cicatricula, but resembles the cicatricula in undergoing complete cleavage or segmentation. The ovum is therefore said to belong to the holoblastic type. It is originally composed of yolk spheres diffused in protoplasm, and contains a germinal vesicle and germinal spot. The process of segmentation in the Mammalian and other ova has recently been studied with great care by several observers, notably by Auerbach,* Bütschli,† Strasburger,‡ Van Beneden, Hertwig, Priestley, and Balfour;§ and the results which have been attained are thus summed up by Mr. Priestley: The primary segmentation nucleus, whose previous history has been already traced (§ 707), elongates so that a spindle-shaped body (Fig. 327) is produced. The extremities of the nucleus exhibit clearer spaces, which radiate into the granular protoplasm, and are united with each other by clear lines, one on each side of the body of the nucleus. During this process the body of the nucleus has become

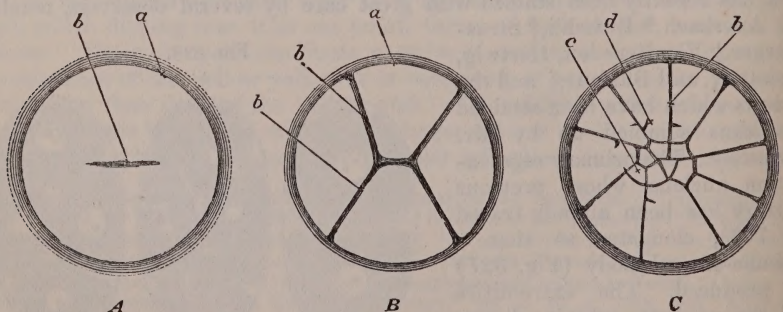
smaller, and it finally disappears, leaving two 'asters' with an intermediate band (Fig. 327 *d*). The granules of the cell substance now begin to recede from a portion of the wall, and a lateral inversion of the margin occurs. The portion thus invaginated is rapidly converted into a furrow, extending around the circumference of the ovum, but beneath the vitelline membrane which is not involved in the process. The furrow deepens, and the protoplasmic mass is thus constricted till it forms two distinct portions (Fig. 328 *a*). Whilst the furrow is still shallow, two vacuoles appear in the band uniting the stars on each side of, and close to, the plane of the equator; these vacuoles commence a movement towards the centres of their respective halves. In the mean time the stellate figures in each half shrink, and as they do so the newly-formed vacuoles increase in size (Fig. 328 *a*). On reaching their destinations the nuclei acquire nucleoli, the bistellate figures gradually disappear, and the division of the ovum into two is complete (Fig. 328 *a*). The subsequent stages of cleavage (Fig. 328 *b*) are but a repetition of the steps above described, except that the later divisions do not appear to involve the entire ovum, as do the first four or five. By such a process of segmentation, the original single ovum becomes subdivided into 8, 12, 16, 24 . . . 96 parts, each of which consists of a nucleated mass of naked protoplasm. At this stage, which is generally reached in the rabbit in less than three days,* the ovum having at first assumed a mulberry-like form (the morula), in which the outer cells are smaller and project over the more internal and larger ones, has given rise to two layers of cells. The more superficial of these cells become somewhat flattened by mutual pressure, and range themselves closely together to form a nucleated cellular layer, which covers the yolk and encloses the large cells, which are also divided from the cleavage of the ovum. At a still later period these large cells cohere to form a second membrane, and there is thus formed the blastoderm. This constitutes the end of the cleavage process, and at the time when the ovum passes into the uterus, the embryo is composed of these two layers, the one being the

FIG. 329.



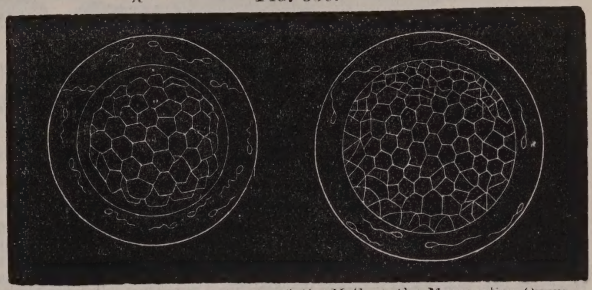
A represents the earliest stage. The first furrow, *b*, has begun to make its appearance in the centre of the germinal disk. In *B* the first furrow is completed right across the disk, and a second similar furrow nearly at right angles to it has appeared. The disk thus becomes divided somewhat irregularly into quadrants by four (half) furrows. In a later stage (*C*) the meridian furrows (*b*) have increased in number from four, as in *B*, to nine, and cross furrows have also made their appearance. The disk is thus cut up into small central (*c*) and larger peripheral (*d*) segments. Several new cross furrows are seen just beginning, as, ex. gr., close to the end of the line of reference (*d*).

ectoderm, the other the mass of endoderm. In birds, the process of cleavage is somewhat different, although it is probably the same in principle. The egg is meroblastic—that is to say, it undergoes only partial segmentation, which is restricted to the cicatricula or germinal disk. The cleavage occurs during the

* Allen Thompson, 'British Assoc. Address, 1877,' "Nature," vol. xvi. p. 307.

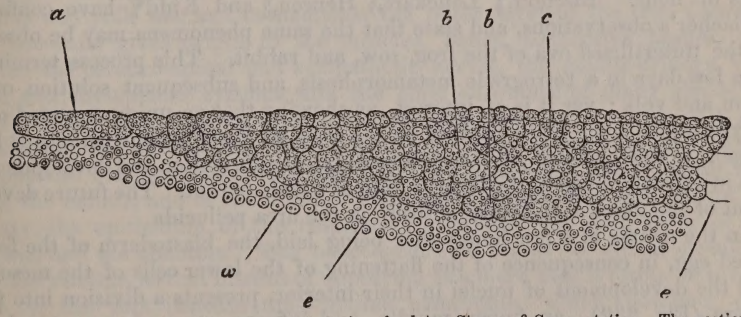
passage of the egg through the oviduct, a progress which usually occupies about twenty-four hours in the common fowl. During this passage the ovum receives the coating of albumin, which afterwards forms the white of the egg, and at the lower part of the oviduct the investing membrane and the shell. The segmentation commences with the formation of a furrow, which is quickly crossed by another at right angles, and soon by others. The examination of hardened specimens of the bird's egg shows that the segmentation is not confined to the surface, but extends through the mass of the blastoderm, and that it takes place not only by vertical but by horizontal furrows, that is, by furrows parallel to the surface of the disk. The original germinal disk is thus broken up, as in the Mammal, into a number of small masses of protoplasm, which are smallest in the centre of the disk and upon the surface; the smaller size of the superficial layer foreshadowing the subsequent division of the blastoderm into two layers, which form the true blastoderm,* or germinal membrane of Pander (Fig. 331). The disk having undergone segmentation

A FIG. 330. B



Later stage in the *Segmentation of the Yolk* of the Mammalian Ovum:—at A is shown the 'mulberry-mass' formed by the minute subdivision of the vitelline spheres; at B, a further increase has brought its surface into contact with the vitelline membrane, against which the spherules are flattened.

FIG. 331.



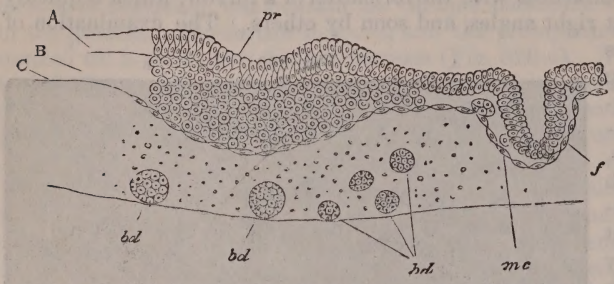
Section of the Germinal Disk of a Fowl during the later Stages of Segmentation. The section, which represents rather more than half the breadth of the blastoderm (the middle line being at *c*), shows that the upper and central parts of the disk segment faster than those below, and at the periphery. In the majority of segments a nucleus can be seen, and one is probably present in all. The segments contain a number of highly refracting spherules. In the central part of the blastoderm the upper cells have commenced to form a distinct layer. No segmentation cavity is present. *a*, large peripheral cell; *b*, larger cells of the lower parts of the blastoderm; *c*, middle line of blastoderm; *e*, edge of the blastoderm adjoining the white yolk; *w*, white yolk.

becomes separated from the white yolk, on which it has hitherto been lying, by a space containing fluid, termed the *segmentation cavity* (see Fig. 332), and with this a distinction becomes apparent between the upper and lower layers of

* For theories in regard to the formation of the blastoderm by secondary segmentation see Ray Lankester 'On the Ova of Cephalopoda,' "Ann. and Mag. of Nat. Hist.," 1873, p. 31; Balfour, 'Development and Growth of the Layers of the Blastoderm,' "Quarterly Journal Microscop. Sci.," 1873, 1874 and 1880; Goette, "Archiv f. Mikroskop. Anat.," x. 1874, and Van Beneden, 'La formation des feuillets chez le Lapin,' "Archiv de Biologie" (1880), tom. i. pp. 128–220.

the segmentation masses. Those of the upper or superficial series assuming a columnar form, and presenting well-defined nuclei, arrange themselves side by side, and constitute a kind of membrane, the Ectoderm or Epiblast (Fig. 331 *a*); whilst those on the lower series, which form the Endoderm, in turn give rise to the Mesoblast and Hypoblast, remain larger (*b*), have no nucleus, or only an indistinct one, and form rather a close irregular network than a distinct membrane. A few of the cells of this layer, constituting the so-called *formative cells** (*bd*, Fig. 332) becoming detached, fall to the bottom of the segmentation cavity, and rest on the white yolk. This is the usual condition of the blastoderm at the time that the egg is laid. Œllacher† describes a process of cleavage similar to that above described, which he has observed in the unimpregnated eggs of hens. Bischoff,‡ Leuckart,§ Hensen,‖ and Kidd¶ have confirmed Œllacher's observations, and state that the same phenomena may be observed in the unfertilized ova of the frog, sow, and rabbit. This process terminates in a few days in a retrograde metamorphosis, and subsequent solution of the germ and yolk; yet it is of interest, as showing that an unimpregnated ovum may advance some little distance on the road to development, and thus lends support to the theory of *parthenogenesis—i.e.*, the formation and development of ova in a female, without the intervention of a male parent. The future development of the chick takes place entirely in the area pellucida.

Fig. 332.



Section of a Blastoderm at right angles to the long axis of the Embryo after eight hours' incubation. Taken about midway between the front and hind end. A, Epiblast; B, Mesoblast; C, Hypoblast; *pr*, primitive groove; *f*, fold in the blastoderm, probably produced by the action of the chromic acid; *mc*, mesoblast cell—the line points to one of the peripheral mesoblast cells lying between epiblast and hypoblast; *bd*, formative cells. The following are the chief points represented in the section :—(1) The thickening of the mesoblast underneath the primitive groove *pr*, even when it is hardly at all present at the sides of the groove; (2) The hypoblast, C, early formed as a single layer of spindle-shaped cells; (3) The so-called segmentation cavity, in which coagulated albumen is present. On the floor of this are the large formative cells *b d*. The line of separation between the epiblast and mesoblast is too strongly marked in the figure.

In the course of a few hours after being laid, the blastoderm of the fecundated egg, in consequence of the flattening of the lower cells of the mesoblast and the development of nuclei in their interior, presents a division into three layers (Fig. 332)—an upper, middle, and inferior—termed respectively the *epiblast* (A), *mesoblast* (B), and *hypoblast* (C). Of these layers, the Epiblast, whose formation has just been traced, increases simply by fission. The origin of the Mesoderm or Mesoblast is involved in considerable obscurity.**

* According to Götte, however, the formative cells, or Dotterzellen, are formed by the segmentation of the white yolk itself. On this point, see P. Kidd, "Quarterly Journ. Microscop. Sci.," vol. xvii. (1877) p. 164.

** In regard to the vexed question of the origin of the mesoblast, see Balfour, "Quart. Journ. Microscop. Sci.," vol. xiii. pp. 266–276, *et auct. ib. cit.*, and 'Development of Elasmobranch Fishes,' Humphry and Turner's "Journal of Anat. and Physiol.," vol. x. 1876; Allen Thomson, "Quain's Anatomy," 8th ed., vol. ii. p. 886; Kölliker, "Entwickelungsgesch. des Menschen," 2nd ed., 1879, p. 99.

According to Balfour it is produced about the sixth or eighth hour of incubation from certain cells either formative or derived from the hypoblast, which collect in the space between the epiblast and hypoblast, and these undergo a process of free cell formation to form a distinct intermediate layer. According to Edward Van Beneden,* however, at the commencement of the sixth day both the cells of the peripheral zone of the gastrodisc, where the ectodermic cells are closely applied to the endoderm, and the more deeply lying cells of the central spot are transformed into flat cells, and thus give rise to a continuous cellular layer, the hypoblast. The cells of the central layer which have not undergone this change form layers intermediate to the ectoderm and hypoblast, which is the mesoblast. The hypoblast and mesoblast are therefore derived from the primary endoderm. The first formation of mesoblast takes place in the centre of the blastoderm, where it fuses with the epiblast and forms an opaque line, the *primitive streak*. The mesoblast appears to grow at the expense of the formative cells, which travel either round or through the substance of the hypoblast; this layer is completed by the 18th–20th hour of incubation. The *Hypoblast*, the lowest of the layers of the trilaminate blastoderm, is formed by some of the cells of the endoderm becoming flattened and nucleated; it appears to grow by the direct conversion of the white yolk spheres into hypoblast cells. According to Remak the *epiblast* gives origin to the brain and spinal cord, to the special modifications of the nerves ministering to special sense, as the Retina, with its pigment layer, the Lens, Auditory hairs, Schneiderian mucous membrane, and the Epidermis, with its epithelial prolongations into the mouth, salivary ducts and cloaca, as well as the cells which form the sheath of the hair bulbs and of the sebaceous and sweat glands, and, as Ranvier has recently shown,† to the muscular coat of the sweat glands; the ascending limb of the Amnion and yolk sac, and in mammals the outer layer of the true Chorion. The *mesoblast* gives origin to the muscles, bones, connective tissues, and dermis, the cerebro-spinal and sympathetic nerves, the genito-urinary, vascular, and chylopoietic systems, and the chief substance of many glands: it also forms the outer layer of the amnion, the vascular layers of the yolk sac, the allantois and chorion, and the embryonic portions of the placenta. From the *hypoblast* originate the epithelium lining the alimentary canal (except that lining the mouth) and of the ducts of the glands connected with it, except the salivary, the epithelium of the respiratory apparatus, the deep layer of the yolk sac, and the allantois. The blastoderm now begins to spread circularly over the vitellus, so that instead of appearing as a mere disk it forms an investment for the yolk beneath the vitelline membrane, which, however, only becomes complete towards the close of the period of incubation. The bag thus produced is chiefly formed by the growth of the area opaca, but in part also, by that of the area pellucida, which gradually assumes an oval and then a pear-shape. In the centre of the area pellucida the longitudinal thickening already alluded to as the *primitive streak*, is seen about the twelfth hour; it is formed by the multiplication of the cells both of the epiblast and of the mesoblast, but chiefly of the mesoblast, and this, again, is quickly marked along the central line by an involution of the epiblast, which gives rise to the *primitive groove*‡ (*pr*, Fig. 333). This is the first indication

* "Archives de Biologie," tom. i. 1880, p. 219.

† "Comptes Rendus," Dec. 29, 1879.

‡ In regard to the primitive groove, see Dr. E. Dursy, "Der Primitive streif des Hühnchens, Lahr.," 1866; Balfour, 'On the Disappearance of the Primitive Groove in the Embryo

of the embryo, which in its further development is formed by a folding-off of the area pellucida from the rest of the blastoderm; the primitive groove disappears as early as the 49th hour of incubation, without entering directly into the formation of any part of the embryo; it is probably the rudiment of some ancestral stage in development which has been lost. According to Mr. Balfour the existence of the primitive groove may be explained as follows:—In all the lower vertebrates the embryo is situated at the edge of the blastoderm, whilst in birds and mammals it is situated in the centre. In the elasmobranch fishes the embryo occupies at first the normal position at the edge of the blastoderm, but in the course of its development the blastoderm grows round the yolk far more slowly in the region of the embryo than elsewhere. As a result of this unequal growth the embryo is left in a bag, the two sides of which eventually meet and coalesce in a linear fashion immediately behind the embryo. The linear streak thus formed gives rise to the primitive groove, which is consequently upon this hypothesis the last indication of a change made by the Avian ancestors in their position in the blastoderm. The first indication of the folding-off of the embryo consists in the formation of a crescentic furrow (Fig. 333, B) at a point which corresponds to the head of the embryo, and very shortly afterwards the tail and lateral folds form, which give rise more and more distinctly to the appearance of a small tubular sac seated upon and connected by a continually narrowing hollow stalk (*the vitelline duct*) with the germinal sac of the blastoderm which encloses the yolk. Soon after the appearance of the primitive streak and groove the mesoblast undergoes a cleavage into two laminæ over its whole extent, with the exception of that part which lies just beneath the axis of the embryo. The upper layer of the mesoblast unites with the epiblast, the lower layer with the hypoblast, and the yolk thus comes to have a double investment beneath the vitelline membrane. In the first formation of the head, tail, and lateral folds, both layers are equally involved, but, as shown in Fig. 334, the lower leaf is folded in more rapidly than the upper one, and a space —the *pleuro-peritoneal cavity* (*pp*, Fig. 334) appears between them. The upper or outer layer forms the *somatopleure* (*F So*), and subsequently gives rise to the body walls of the embryo. The lower or inner layer forms the *splanchnopleure* (*Sp*), and its opposite folds meeting sooner than those of the

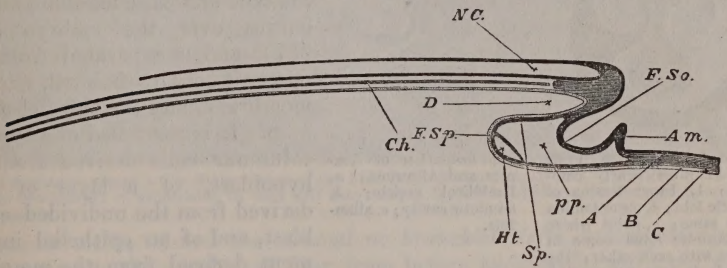
Chick,' "Quarterly Journ. Microsc. Sci.," vol. xiii. (1873) p. 276, and the "Development of Elasmobranch Fishes," Humphry and Turner's "Journal of Anatomy and Physiol.," vol. x. (1875), p. 682; and in a review of the second edition of Kölliker's work, ibid., pp. 790 and 791; 'On the Development of the Lacertilia together with some Observations on the Nature and Relation of the Primitive Streak,' "Quarterly Journal of Micros. Sci.," vol. xix. (1879) pp. 426–430; Kölliker, "Entwickelungsgeschichte," 1879, pp. 134–138.

upper layer, constitute the intestinal tube.* At about the 16th hour a thickening of the mesoblast occurs in front of the primitive groove, ending in front as the head fold (Fig. 333 *B*, Fig. 334). The surface of this is marked by a groove (*m c*, Fig. 333), termed the medullary groove, the sides of which constituting the *medullary folds* or *laminæ dorsales*, gradually arching over till they meet and fuse, enclose the *medullary canal.* Immediately beneath the groove the cells form a flattened cylindrical rod—the *notochord*, which is the precursor of the vertebral column (N.C., Fig. 334).

Fig. 334.



Diagrammatic Longitudinal Section through the Axis of an Embryo. *F.So.*, Fold of the somatopleure. *F.Sp.*, Fold of the splanchnopleure. The line of reference, *F.So.*, is placed in the lower bay, outside the embryo. The line of *D* is placed in the upper bay, inside the embryo; this will remain as the alimentary canal. Both folds (*F.So.*, *F.Sp.*) are parts of the head fold, and are to be thought of as continually travelling onwards (to the left) as development proceeds. *p p*, Space between somatopleure and splanchnopleure or pleuro-peritoneal cavity. *Am.*, Commencing (head) fold of the amnion. The tail fold has not yet appeared. *N.C.*, Neural canal, closed in front, but as yet open behind. The section being taken in the middle line, the protovertebræ are of course not shown. In front of the notochord is seen a mass of uncleft mesoblast, which will eventually form part of the skull. *D*, Commencing foregut, or front part of the alimentary canal. *A*, Epiblast. *B*, Mesoblast. *C*, Hypoblast. *Ht.*, Commencing heart.

Formation of Amnion and Allantois.—Coincidentally with the formation of the head fold, a second fold (Fig. 334, *A m*) appears a little in front of it, and soon others arise at the tail end and sides of the embryo, which, unlike the head fold, are formed exclusively of the somatopleure—*i.e.*, of the epiblast and a thin layer of mesoblast, and gradually rising, bend over the body of the embryo (Figs. 336, *d e;* 339, *a f*), and coalesce (*c*, Fig. 337). These are the *amniotic folds.* Each fold necessarily consists of two limbs. After their coalescence the septum disappears and two spaces exist: one which is continuous with the pleuro-peritoneal cavity between the outer and inner limbs, and one between the inner limb and the body of the

* The quadrilaminate, or secondary blastoderm thus formed, is produced in the following way (Allen Thomson's "Address," loc. cit.):—

Primary blastoderm	Ectoderm		Epiblast	Secondary Blastoderm.
	Mesoderm	Somatopleure		
		Splanchnopleure		
	Endoderm		Hypoblast	

embryo. The former is the space into which the *allantois* or respiratory organ of the embryo projects; the latter is the amniotic sac, and is subsequently filled by the amniotic fluid. The allantois (Fig. 338,*c*) is not formed till the second or third day, when it appears as a bud thrown out by the splanchnopleure close to its junction with the somatopleure at the hinder end of the embryo, and gradually insinuating itself first into the pleuro-peritoneal cavity, and then between the true and false amniotic sacs, it curves over the embryo (Fig. 337), and is separated from the outer air only by the shell, vitelline membrane, and the thin false amnion. It is composed of a layer of columnar cells derived from the hypoblast, of a layer of cells derived from the undivided mesoblast, and of an epithelial investment derived from the mesoblast of the splanchnopleure.* It receives at an early period branches from the iliac arteries, which subsequently constitute the umbilical vesssels, and are developed in an extension of the mesoblast cells of the area opaca, known as the *vascular area.*

The first rudiment of the *heart* in the chick appears as a solid thickening of the mesoblast of the splanchnopleure just beneath the anterior extremity of the foregut. It soon becomes hollow, and receives behind the blood of the two omphalo-mesaraic veins, which ramify over the yolk-sac, whilst in front it gives off the two aortæ, which bend round the front end of the foregut and gain its upper side, when they turn back and run in the mesoblast on each side of the notochord to the tail.† About the middle of the embryo each gives off a large omphalo-mesaraic artery, which is distributed over the pellucid and vascular areas, from whence the blood is returned by the omphalo-mesaraic veins (Fig. 344, *R. Of. A, L. Of. A.*). At the close of the first day *the protovertebræ* begin to form in the uncleft portion of the mesoblast near the middle line, which is called the vertebral plate. The first one to make its appearance is the body of third or second cervical, others soon becoming segmented off the vertebral plate both before and behind. At this time the forepart of the medullary canal with its optic and cerebral vesicles,

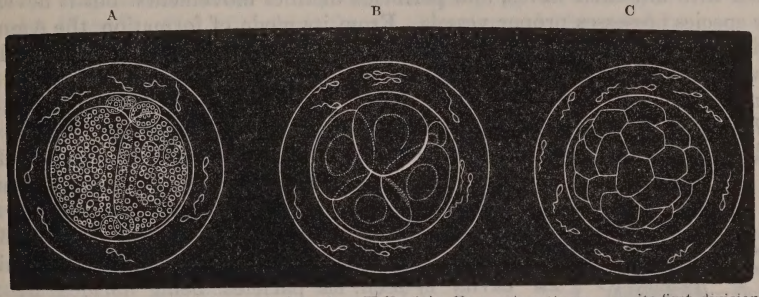
† According to Mr. Balfour ("Quarterly Journal Micros. Sci.," vol. xiii. (1873) p. 289), the cavity of the heart is produced by a splitting or absorption of the central cells of the thickened mesoblast of the splanchnopleure, whilst its muscular walls are formed from the remaining cells of the thickened portion.

which has hitherto been straight, begins to curve over the anterior extremity of the notochord, which is the commencement of the *cranial* flexure; and soon after the whole embryo becomes curved upon itself. On the third day certain

FIG. 340.



Progressive stages in the *Segmentation of the Yolk* of the Mammalian Ovum: A, its first division into two halves; B, subdivision of each half into two; C, further subdivision, producing numerous segments.

fissures or clefts, termed the *visceral* or *branchial clefts*, appear, developing in succession to the number of four from before backwards, and from within outwards. The anterior border of each forms a visceral or branchial fold, so that there are five folds. The first pair form the inferior maxillæ, and by a pair of buds they give off from their upper border the superior maxillæ. Other structures are formed in the remaining folds, which will hereafter receive mention.

735. Returning now to the development of the Mammalian ovum we find that the fine membrane covering and enclosing the blastodermic vesicle begins to show small mammillary eminences, whence the name which has been suggested for this membrane, of *Chorion primitivum* or *Membrana ovi externa*. The ovum at this period, therefore, consists of the external villous membrane or primitive chorion; of the blastodermic vesicle, composed of two layers; and of the cellular yolk. As in the Bird, the area germinativa at its first appearance has a rounded form, but it soon loses this, first becoming oval and then pear-shaped (Plate II., Fig. 11). The centre becomes clear, and constitutes the *area pellucida* (*b*), and this is bounded by a more opaque circle, the *area opaca* (*a*). The first appearance of the embryo in the form of the primitive trace with the subsequent formation of the medullary groove followed by the elevation of the *laminæ dorsales*, their junction in the middle line, and expansion anteriorly into three vesicles (Plate II., Fig. 12), afterwards to be developed into the *prosencephalon*, *mesencephalon*, and *epencephalon;* the formation of the amnion by the growth of two folds of the epiblast, and the growth of the allantois into its cavity differ in no essential respect from the similar processes in the chick, though the allantois never attains the same degree of development in the mammal. A microscopic

FIG. 341.

examination of the Amniotic membrane in the Human subject shows that it consists of an inner layer of tessellated epithelium, and an outer layer, which even at the fourth week presents spindle-shaped corpuscles, and at the seventh week has become well-marked connective tissue. In some animals it is provided with muscular fibres, and performs distinct movements but it never in any species possesses proper vessels. From its mode of formation, the Amnion is directly continuous with the skin of the embryo, and the Amniotic fluid in which the fœtus floats occupies the space between the inner layer and the skin.

736. As the development of the embryo progresses, the walls of the abdomen and the coats of the intestines begin to be formed by the bending downwards and forwards of the lateral portions of the blastodermic vesicle, termed respectively the *somatopleure* and the *splanchnopleure*. In Fig. 342, the mode of the development of the abdominal cavity is seen, its parietes being formed by the somatopleure, composed of the epiblast with some mesoblast (*bh*), whilst within it the deep groove of the intestines (*d*) appears, the walls of which or splanchnopleure are composed of two laminæ, the mesoblast (*df*), and the hypoblast (*d*), passing into the corresponding laminæ of the blastodermic vesicle, which already form the vitelline sac. The incipient intestine is maintained in its place by the mesentery, which begins to be formed out of a prolongation of the mass lying in front of the notochord or chorda dorsalis, in which lie the now symmetrical aorta (*sa*) and the cardinal vein (*vc*), and which is obviously only a thickened portion of the connecting band between the somatopleure and the splanchnopleure.—During the same period, a very important provision for the future support of the embryo begins to be made, by the development of Blood-vessels and the formation of Blood. Hitherto, the embryonic structure has been nourished by direct absorption of the alimentary materials supplied to it by the yolk; but its increasing size and the necessity for a more free communication between its parts than any structure consisting of cells alone can permit, call for the development of *vessels* through which the nutrient fluid may be conveyed. These vessels are first seen in *the vascular area* or that part of the germinal membrane which immediately surrounds the embryo.* In their earliest stage of development these vessels appear as *two arcus aortæ*, proceeding from the anterior part of the heart, which after a short course in the forward direction, bend backwards and run on each side of the notochord immediately beneath the aorta towards the caudal extremity. In this course, each of the primitive aortæ gives off a large vessel, the *omphalo-mesaraic artery*. At a very early

FIG. 342.

The mass around the chorda contains the vessels anteriorly, and in front, in the middle line, is prolonged as the mesentery.

* According to His (loc. cit. p. 95), Wolff, and Pander, in the chick a peripheral vessel around the germinal area, and others in the area opaca, first appear, whilst at various points small coloured masses, surrounded by a membrane or blood-islands, are developed. Both the vessels and the blood proceed directly from the white or germ-yolk. The formation of the vessels precedes that of the heart, and is quite independent of it.

period of development the two primitive aortæ unite in a single, short, symmetrical aortic tube, from which again two branches almost immediately arise, the *arteriæ vertebrales posteriores*. These, lying beneath the chorda dorsalis, extend to the posterior part of the body of the embryo, dividing ultimately into the omphalo-mesaraic, or Vitelline vessels (Fig. 344, *R.Of.A.*, *L.Of.A.*; see also Plate II., Fig. 13) which form a close network, bounded by a circular channel termed the *Vena* or *Sinus terminalis* (Fig. 344, *S.T.*). This network or vascular area soon extends itself, and the vessels finally spread over the whole of the membrane that contains the yolk. At the anterior part of the embryo the two extremities of the circular channel form the *Venæ omphalo-mesaraicæ*, which discharge their contents into the back part of the heart.—At this period the Yolk-sac is entirely separated in the Mammalia, by a constriction of the portion which is continuous with the abdomen of the embryo (Fig. 347, *b*); and it is known from that time under the name of the *Umbilical Vesicle* (Plate I., Fig. 10, *i*). The communication, however, remains open for a time through the 'vitelline duct;' and even after this has been cut-off, the trunks which connect the circulating system of the embryo with that of the vascular area are discernible. The two first veins, then, that are developed, are the Venæ omphalo-mesaraicæ, which belong not to the body of the embryo itself, but to the germinal area, and open by a short tube common to both into the posterior extremity of the Heart (Fig. 343, 1, *om*). Subsequently, by the extension of their branches over the Yolk-sac, they become the *vitelline vesssls*, still opening by two veins into the heart, and effecting the absorption of the yolk. With the formation of the intestine, however, the vessel of the right side disappears, the left alone remaining (Fig. 343, 2, *om''*), which is soon joined by a small mesenteric vessel from the intestine (Fig. 343, 3, *m*). Before this is accomplished, however, the Allantois has been developed, and to this organ two large branches pass from the Iliac Arteries, which are named *umbilical arteries;* the blood returning from it after aëration enters the two Venæ umbilicales which pass forwards and open into the common trunk of the Venæ omphalo-mesaraicæ (Fig. 343, 1, *u'u''*). The Venæ umbilicales rapidly increase in size, preponderating so much over the only remaining Vena omphalo-mesaraica, into which they originally

FIG. 343.

At the time of the first appearance of the branches to and from the liver, and the diminution of the omphalo-mesaraic vessels. 3, 4. At the period of complete fœtal circulation in 1, omphalo-mesaraic trunk; in 2, 3, remains of it; in 4, vein of the yolk-sac alone; *om'* right and *om''* left vena omphalo-mesaraicæ; *u*, ductus venosus; *u'* right and *u''* left vena umbilicalis; *dc*, ductus Cuvieri; *j*, jugularis; *c*, cardinalis or Wolffian vein; *l*, liver; *ha*, hepaticæ advehentes; *hr*, hepaticæ revehentes; *m*, mesenterica; *da*, sinus venosus; *ci*, cava inferior; *p*, vena portæ; *l*, lienalis; *m*, mesenterica superior.

discharged their contents, that the latter now appears to be merely a tributary branch. As the Liver becomes developed, it surrounds the trunk of the umbilical vein, the portion thus surrounded taking the name of the *Ductus venosus* (Fig. 348, *v*), which soon forms a twofold system of tubes within that gland, the one conveying the blood to the liver, the Venæ hepaticæ advehentes; the others returning the blood from the gland substance to the umbilical vein again, and constituting the Venæ hepaticæ revehentes. The

Fig. 344.

right umbilical vein now disappears, and the blood returning from the placenta altogether traverses the left vein, which soon takes up a median position; the remains of the omphalo-mesaraic vessel (*om*, Fig. 343, 4), together with branches (*m*) derived from the intestine, ultimately come to open into the right *vena hepatica advehens* of the umbilical vein, and thus constitute the origin of the portal vein. That portion of the umbilical vein which lies between the two systems of hepatic branches just mentioned, remains throughout the whole of fœtal life, and is termed the Meatus venosus Arantii. It was formerly believed that the nutrient matter of the yolk passed directly through the vitelline duct, into the (future) digestive cavity of the embryo, and was from it absorbed into its structure; but there can now be little doubt, that the vitelline vessels are the real agents of its absorption, and that they convey it through the general circulating system, to the tissues in process of formation. They correspond, in fact, to the Mesenteric veins of

Invertebrate animals, which are the sole agents in the absorption of nutriment from their digestive cavity; and the blastodermic vesicle is to be regarded as the temporary stomach of the embryo—remaining as the permanent stomach in the Echinodermata.

737. The first rudiment of the Mammalian *Heart*, which is the earliest of the permanent organs of the embryo that comes into functional activity, consists, according to Kölliker,* at a period antecedent to the closure of the medullary folds of two widely separated portions lying on each side of the embryo, connected with a vein posteriorly, and with an artery anteriorly. Each half is formed by the invagination of the splanchnopleure, and is enclosed in the cervical cavity; the invaginated portion itself containing the endothelial lining. As development proceeds the two parts of the heart gradually approximate, until they are only separated from each other by a median septum. The septum is afterwards absorbed, and the heart thus possesses for a time but a single cavity. For a long time after it has distinctly commenced pulsating, and is obviously exerting a contractile force, its walls retain the cellular character, and only become muscular by a progressive histological transformation. The first appearance of the Heart in the Chick is at about the 27th hour; but the time of its formation in Mammalia has not been distinctly ascertained. In its earliest form it has the same simple character which is presented by the central impelling cavity of the lower Invertebrata, being a mere prolonged canal, which at its posterior extremity receives the veins, and at its anterior sends forth the arteries. About the 15–18th day in the Human Embryo it becomes doubly bent upon itself (Plate II., Fig. 13, *d*, and Fig. 345, A, B), one loop corresponding to the arterial, the other to the venous portion. After this, two slight enlargements (*b*) are observed in the venous bend; and the arterial bend separates into two parts by a long line of division. The two enlargements represent the auricles, and receive the venæ omphalo-mesaraicæ (*a*), which run outwards in the folds of the Splanchnopleure. Above, they open into the atrium (*c*), which leads to the right ventricle (*d*), and this again into the bulbus aortæ. The circulation is at first carried on exactly upon the plan which is permanently exhibited by Fishes. The Aorta subdivides on either side of the neck into three or four arches (Figs. 344, 350, *e*, *e'*, *e''*), which are separated by fissures much resembling those forming the entrances to the gill-cavities of Cartilaginous Fishes; and these arches re-unite to form the descending aorta, which transmits branches to all parts of the body.

The development of the blood-vessels has been investigated by Dr. Klein,† and by Mr. Balfour,‡ who agree in stating that they arise as a network formed by the united processes of the mesoblast cells of the Splanchnopleure. The nuclei of the cells multiply by fission; some of them become circular and acquire a yellowish colour, forming in this way the first stage in the production of a red blood-corpuscle. Others become elongated to form fusiform cells, which arrange themselves so as to enclose the

* Op. cit. pp. 289–296. † Band liii., der K. Akad. der Wiss. der Wien.

‡ "Quarterly Journ. of Microscop. Sci.," vol. xiii. (1873), p. 280.

protoplasmic processes; the processes themselves becoming liquified to form the plasma in which the corpuscles float. The formation of corpuscles occurs earliest in the central part of the hour-glass shaped pellucid area, and latest in its anterior part. The coloured corpuscles subsequently undergo increase by a process of fission which occurs within the vessels. The origin of the white corpuscles has not been clearly ascertained. The origin of the red corpuscles in Mammalian blood has recently been studied by Professor Rindfleisch,* who has been led to the conclusion that the nucleus of the red coloured cell of the red bone marrow escapes and atrophies whilst the body of the cell contracts and becomes the red corpuscle. Such is the first phase or aspect of the Circulating Apparatus, which is *common to all Vertebrata* during the earliest period of their development, and which may, therefore, be considered as its most general form. It remains permanent in the class of Fishes; and in them the vascular system undergoes further development on the same type, a number of minute tufts being sent forth from each of the arches, which enter the filaments of the gills, and are thus subservient to the aëration of the blood. In higher Vertebrata, however, the plan of the circulation is afterwards entirely changed, as will be presently described, by the formation of new cavities in the heart, and by the production of new vessels; it is incorrect, therefore, to speak of the vascular arches in *their* necks as *branchial* arches, since no branchiæ or gills are ever developed from them. The clefts between them may be very distinctly seen in the Human Fœtus towards the end of the first month; during the second, they usually close up and disappear.

FIG. 346.

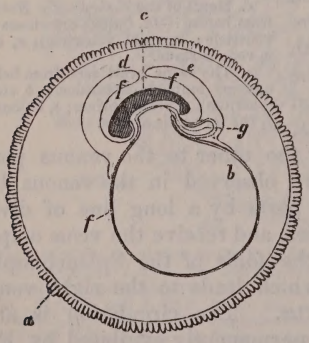

FIG. 347.

738. With the evolution of a Circulating apparatus, adapted to absorb nourishment from the store prepared for the use of the Embryo, and to convey it to its different tissues, it becomes necessary that a Respiratory apparatus should also be provided, for depurating the blood from the carbonic acid with which it becomes charged during the course of its circulation. The temporary

* "Archiv f. Micros. Anat.," vol. xvii. (1879), abstracts of whose Paper will be found in the "British Medical Journal," May 22, 1880, p. 789, and in the "Quarterly Journal of Micros. Sci.," 1880. See also Prof. Pouchet's paper, ibid. July, 1880.

Respiratory apparatus now to be described bears a strong resemblance in its own character, and especially in its vascular connections, to the gills of the Mollusca; which are prolongations of the external surface (usually near the termination of the intestinal canal), and almost invariably receive their vessels from that part of the system. This apparatus, which is termed the *Allantois*, sprouts forth from the splanchnopleure at the posterior extremity of the embryo and close to its junction with the somatopleure, at first as a little mass of cells, which soon exhibits a cavity (probably originating in the liquefaction of the cells of the internal part), so that a vesicle is formed (Figs. 346, 347, *g*), which looks like a diverticulum from the lower part of the digestive cavity. It appears at a very early period of fœtal life, and in the human embryo soon disappears. The outer cells are composed of mesoblast, the internal of hypoblast. This vesicle, in Birds, has been shown by Vulpian* to be possessed of a distinct contractile power, and soon becomes so large as to extend itself around the whole yolk-sac, intervening between it and the membrane of the shell, and coming through the latter into relation with the external air; but in the embryo of Mammalia, the allantois, being early superseded by another provision for the aëration of the blood, seldom attains any considerable dimensions. Its chief office here is to convey the vessels of the embryo to the Chorion; and its extent bears a pretty close correspondence with the extent of surface through which the Chorion comes into vascular connection with the decidua. Thus, in the Carnivora, whose placenta extends like a band around the whole ovum, the allantois also lines nearly the whole inner surface of the chorion; on the other hand, in Man and the Quadrumana, whose placenta is restricted to one spot, the allantois is small, and conveys the fœtal vessels to one portion only of the chorion. At first the Allantois carries two arteries and two veins, but of these the right vein soon becomes obliterated, and there remains from the fifth week to the time of birth a single vein to two arteries. When these vessels have reached the chorion, they ramify in its substance, and send filaments into its villi; and in proportion as these villi form that connection with the uterine structure which has been already described (§§ 708–714), do the vessels increase in size. They then pass directly from the fœtus to the chorion; and the allantois, being no longer of any use, shrivels up, and remains as a minute vesicle only to be detected by careful examination. The same thing happens in regard to the umbilical vesicle, from which the entire contents have been by this time withdrawn; and from henceforth the fœtus is completely dependent for the materials of its growth upon the supply it receives through the Placenta, which is conducted to it by the vessels of the umbilical cord. This state of things is represented in Figs. 348, 349, *n n'*, *o o'*.—The Allantois is commonly said to give origin to the Urinary Bladder; but this organ is really formed by an enlargement of the upper part of the uro-genital sinus (§ 746), with which the allantois communicates by a duct which gradually shrivels, only a vestige of it remaining permanent, to form the Urachus or suspensory ligament of the bladder, by which this is connected with the umbilicus. Before this takes place, however, the Allantois is the receptacle for the secretion of the Corpora Wolffiana, and also for that of the true Kidneys, when they are formed.

739. It will be seen from the succeeding diagram that the *Amnion* forms a kind of tubular sheath around the umbilical cord; it is continuous at the umbilicus with the integument of the fœtus; and at the point where the cord enters the placenta it is reflected over its internal or fœtal surface. It

* "Journ. de la Physiologie," tom. i. p. 619 *et seq.*

thus forms a shut sac, resembling that of the pleura, arachnoid, &c.; and it contains a fluid known as the *liquor amnii*, which consists of water holding in solution a small quantity of casein, kreatin, lactic acid, grape sugar,* and saline matter, and resembles, therefore, very dilute serum. At a late period of pregnancy it contains in addition, glycogen, traces of the bile salts, and urea. Like the Allantois it possesses a contractile power, owing to the unstriated muscle which it obtains from the somatopleure. During the first two months of gestation, the amnion and the inner lining of the chorion (which is really the reflected layer of the amnion, Fig. 347, *h*, just as the lining of the abdominal cavity is formed by the peritoneum) are separated by a gelatinous-looking substance; which probably aids in the nutrition of the embryo, previously to the formation of the placenta. This is absorbed during the second month; and the amnion is then found immediately beneath the chorion.—In the *Umbilical Cord*, when it is completely formed, the following parts may be traced. 1. The tubular sheath afforded by the Amnion. 2. The Umbilical Vesicle (Fig. 348, *t*), with its pedicle, or vitelline duct. 3. The Vasa Omphalo-Mesaraica (*q*, *r*), or mesenteric vessels of the embryo, by which the

yolk was absorbed into its body; these accompany the pedicle. 4. The Urachus, and remains of the Allantois. 5. The Vasa Umbilicalia (*n*, *n*, *o*), which in the later period of gestation constitute the chief part of the Cord.

* Hoppe-Seyler, "Handbuch der Chem. Anal.," 1867, p. 502.

These last vessels consist in Man of two arteries and one vein. The arteries are the main branches of the Hypogastric; and they convey to the placenta the blood which has to be aërated, and otherwise revivified, by being brought into relation with that of the mother. The vein returns this to the fœtus, and discharges a part of it into the Vena Portæ, and a part directly through the Ductus Venosus into the Vena Cava. Mr. Lawson Tait has recently made some careful investigations into the structure of the Umbilical Cord.* He believes that the growth of the cord and its spiral direction are due to a mechanism in immediate relation to the umbilical vein, and to the unequal nutrition of the cord as provided for by the varying size of the capillaries in the cord itself. Thus at some places the capillaries are only one millimetre in length, whilst at others they are 8 or 10 millimetres. As a consequence of such an unequal supply of blood, growth would result in a spiral direction. The epithelium covering the cord is continuous with the epithelium of the amniotic surface of the placenta; it consists of a single layer of irregularly polygonal nucleated cells, embedded in a thin and structureless fibrillar matrix. Wharton's jelly is composed of a number of small canals, which are probably in direct connection with the amniotic cavity. The canals are arranged in three columns, which are separated from each other, one column surrounding each blood-vessel. The substance of the cord is not nourished by the umbilical vessels which pass through it, but by a sacculated sinus, which appears to have a spiral arrangement, and extends from the omphalic ring into the substance of the cord. It gives off at short intervals thick trunks, which rapidly break up into capillaries. The blood-vessels of the cord are surrounded by the canalicular tissue which takes the place of their external coat; the arteries possess no endothelial lining, and their muscular coat is exceedingly thick. No nerve fibres have been traced in any part of the cord.

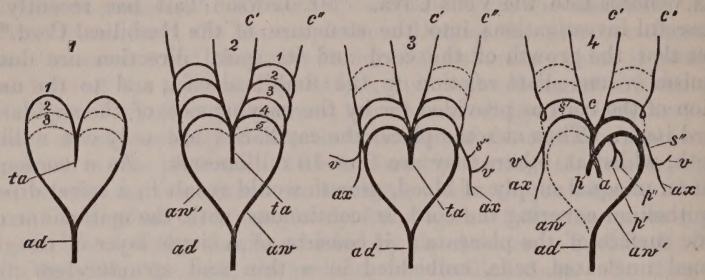
740. A change in the type of the Circulating system of the fœtus, from that at first presented by it (§ 735) takes place at a very early period. Between the fourth and eighth week the venous portion of the heart becomes much enlarged, and a septum, which arises from the lower part of the right wall, and gradually grows towards the auriculo-ventricular aperture, begins to be formed. This partition gradually divides the single ventricular cavity into two, the separation being completed at the seventh week. The septum of the auricles commences in the eighth week, as a fold, proceeding from the anterior wall, starting from the septum of the ventricles, it grows backwards towards the entrance of the sinus, stopping short of it at some distance.† It remains incomplete throughout the whole of fœtal life, the opening being termed the foramen ovale, and being guarded by the Eustachian valve. Contemporaneously with the formation of these septa, a transformation occurs in the arrangement of the Arterial trunks proceeding from the heart, which ends in the assumption of the form they present until the end of Fœtal life; and this undergoes but a slight alteration, when the plan of the circulation is changed at the moment of the first inspiration. The number of aortic arches on each side, which was five at first, soon becomes reduced in the Mammalia to three, by the obliteration of the central portions of the two highest pairs. The Bulbus Aorticus is subdivided by the adhesion of its walls at opposite points into two tubes, of which one becomes the origin of the aorta, and the other that of the pulmonary artery, and of the three remaining pairs of vascular (branchial) arches, the third being connected with the aortic trunk, contri-

* "Proceedings Royal Soc.," vol. xxiii. p. 498, and 1876, p. 417.

† Quain's "Anatomy," ed. 8, p. 788.

butes, with portions of the two highest pairs, to the formation of the external and internal carotid arteries; whilst of the second pair, the arch on the right side forms the innominate and the beginning of the right subclavian, and the other becomes the arch of the aorta, and contributes to form the left sub-

FIG. 350.



1. *Bulbus arteriosus*, with one pair of aortic arches, and dotted outlines indicating the future position of the second and third pairs. 2. *Bulbus arteriosus*, with four pairs of aortic arches and indications of the fifth. 3. *Bulbus arteriosus*, with the three posterior pairs of aortic arches, from which the permanent vessels of the embryo are developed, with dotted outlines showing the position of the two (now) obliterated anterior arches. 4. Permanent arterial trunks in their primitive form, the obliterated portions still shown in dotted outline. 1—5, primitive aortic arches; *a*, aorta; *p*, pulmonary artery; *p'*, *p''*, branches to the lungs; *aw'*, root of thoracic aorta (*ad*) on left side; *aw*, obliterated root springing from right side; *s'*, *s''*, subclavian artery; *v*, vertebral; *ax*, axillary; *c*, common carotid; *c'*, external carotid; *c''*, internal carotid. In the chick the part *s'* has been observed to atrophy, the vessel *c'* becoming the external, and *c''* the internal carotid artery.

clavian. The lowest pair is entirely obliterated on the right side. On the left, it gives off the pulmonary artery, and remains throughout fœtal life in communication with the aorta, as the Ductus Arteriosus or Ductus Botalli.*— A knowledge of these different stages in the development of the Heart and Arterial system enables us to explain many of the malformations which they occasionally present in Man; these being for the most part due to arrest of development, whereby the circulating apparatus is permanently fixed in conditions that are properly characteristic of cold-blooded animals. And it is interesting to remark, too, that the varieties which not unfrequently present themselves in the arrangement of the principal trunks given off from the Aorta, find their analogues in the arrangements that are normally characteristic of some one or other of the Mammalia.

741. The *Venous* system of the body generally undergoes changes which are even more remarkable than those of the arterial trunks. In its earliest condition, it has been ascertained by Rathke† to present essentially the same type in the embryos of all Vertebrate animals; the peculiarities of each group being acquired by a process of subsequent transformation. There is at first a pair of anterior venous trunks (Figs. 348, 349, *g g'*,) receiving the blood from the head, and a pair of posterior trunks (*k k'*), formed by the confluence of the veins of the trunk, of the Wolffian bodies, &c.; the former are persistent as the jugular veins; the latter remain separate in most Fishes, where they are designated the cardinal veins; but in Man (as in warm-blooded Vertebrata generally), they are only represented by the *venæ azygos* major and minor,‡ which coalesce into a common trunk for a considerable part of their length. One of the anterior trunks and one of the posterior unite on either side to form a canal, which is known as the Ductus Cuvieri; and the ducts of the two sides coalesce to form a shorter main canal, the sinus venosus,

* Kölliker, "Entwickelungsgeschichte des Menschen," ed. 2 (1879), p. 918.
† "Ueber den Bau und die Entwickelung des Venensystems der Wirbelthiere," 1838.
‡ See Müller's "Vergleichende Anatomie der Myxinoiden," Berlin, 1840.

which enters the auricle, at that time an undivided cavity. This common canal is absorbed into the auricle at an early period in all Vertebrata above Fishes; and after the septum auriculorum is formed, the two Cuvierian ducts, which have previously altered their position in relation to the heart, separately enter the right auricle, each being then known as a vena cava superior. This arrangement is persistent in Birds and the inferior Mammals, in which we find at a later period two Venæ Cavæ superiores, entering the right auricle separately; but in the higher Mammalia and in Man, the left duct is obliterated, with the exception of its lower extremity, which remains as the coronary sinus, and the right alone remains as the single Vena Cava superior, a transverse communicating branch being formed, to bring to it the blood of the left side.* The double Vena Cava sometimes presents itself as a monstrosity in the Human subject. The obliterated portion of the left superior vena cava can in many cases be distinguished in the adult as a fibrous cord running in the pericardium on the left auricle, and in front of the root of the left lung, and forming the *vestigial fold* of Marshall. As the anterior extremities are developed, the subclavian veins are formed to return the blood from them; and these discharge themselves into the jugulars. The Omphalo-Mesaraic vein (Fig. 349), which has been already (§ 734) shown to be formed by the confluence of the veins of the yolk-bag and intestinal canal, passes by itself, with the two Cuvierian ducts, into the auricle. The upper part of this remains to constitute the upper part of the Inferior Cava (Figs. 348, 349, *j*), the lower portion of which arises between the Wolffian bodies, and originally enters the omphalo-mesaraic vein above the liver. The Inferior Cava, which receives the hepatic vein, is gradually enlarged by the reception of most of the veins from the inferior part of the trunk and the lower extremities, and the Vena Azygos is reduced in the same proportion; in some rare cases of abnormal formation, however, the vena cava fails to be developed, and then the blood from the lower parts of the body is conveyed to the superior cava through the system of the vena azygos.

742. The following is the course of the Circulation in the mature Fœtus.—The fluid brought from the Placenta by the umbilical vein, is partly conveyed at once to the ascending Cava by means of the ductus venosus; but some branches are sent to each lobe of the liver, whilst others open directly into the vena portæ, and in either of these cases the blood reaches the vena cava inferior through the hepatic veins after it has passed through the hepatic capillaries. Having thus been transmitted through the great depurating organ, the Placenta, and the great assimilating organ, the Liver,† it is in the condition of arterial blood; but, being mixed in the great vessels with that which has been returned from the trunk and lower extremities, it loses this character in some degree by the time that it arrives at the Heart. In the right auricle, which it then enters, it would be also mixed with the venous blood brought thither by the descending Cava; were in not that a very curious provision exists to prevent (in great degree, if not entirely) any such further dilution. The Eustachian valve, which is situated at the lower margin of the vena cava inferior at the point where it opens into the right

* See the elaborate Memoirs 'On the Development of the Great Anterior Veins of Man and Mammalia' ("Phil. Trans.," 1850), by Mr. J. Marshall; who has further shown that some vestiges of the original arrangement may be traced even in the normal condition of the venous system in the adult.

† It does not seem probable that the depurating action of the Liver can be energetically performed during fœtal life; and its large dimensions and copious supply of blood appear rather to be referable to its function as a *blood-making* gland.

Fig. 351.

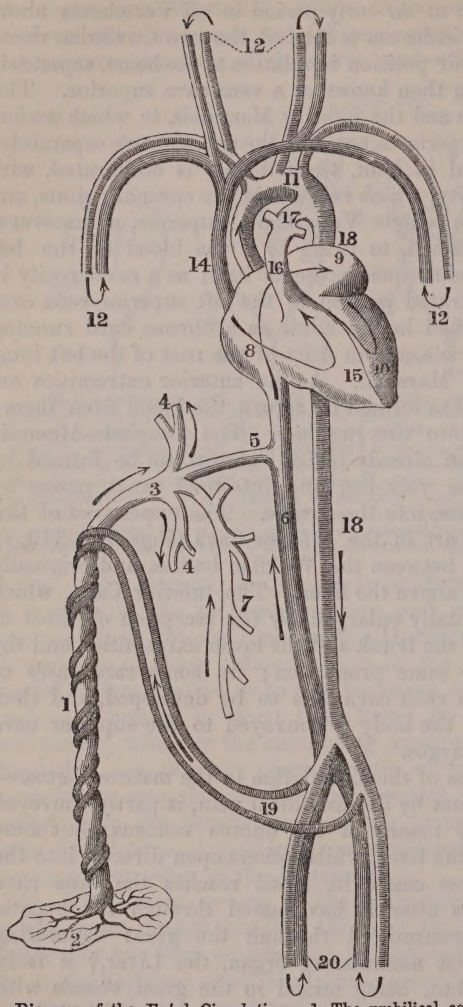


Diagram of the *Fœtal Circulation*:—1. The umbilical cord, consisting of the umbilical vein and two umbilical arteries, proceeding from the placenta (2). 3. The umbilical vein dividing into three branches: two (4, 4) to be distributed to the liver, and one (5), the ductus venosus, which enters the inferior vena cava (6). 7. The portal vein, returning the blood from the intestines, and uniting with the right hepatic branch. 8. The right auricle; the course of the blood is denoted by the arrow proceeding from 8 to 9. 9. The left auricle. 10. The left ventricle; the blood following the arrow to the arch of the aorta (11), to be distributed through the branches given-off by the arch to the head and upper extremities. The arrows (12) represent the return of the blood from the head and upper extremities through the jugular and subclavian veins, to the superior vena cava (14), to the right auricle (8), and in the course of the arrow through the right ventricle (15), to the pulmonary artery (16). 17. The ductus arteriosus, which appears to be a proper continuation of the pulmonary artery; the offsets at each side are the right and left pulmonary arteries cut off. The ductus arteriosus joins the descending aorta (18, 18), which divides into the common iliacs, and these into the internal iliacs, which become the umbilical arteries (19), and return the blood along the umbilical cord to the placenta, and the external iliacs (20), which are continued into the lower extremities. The arrows at the termination of these vessels mark the return of the venous blood by the veins to the inferior cava.

auricle, has been found, by the experiments of Dr. J. Reid,* to serve the purpose of directing the *arterial* blood, which flows upwards from the *ascending* Cava, through the foramen ovale, into the *left* auricle, whence it passes into the *left* ventricle; whilst it also directs the *venous* blood, that has been returned by the *descending* Cava, into the *right* ventricle. When the ventricles contract, the arterial blood which the left contains is propelled into the ascending Aorta, and supplies the branches that proceed to the head and upper extremities, before it undergoes any admixture; whilst of the venous blood contained in the right ventricle, part is transmitted by the Pulmonary artery to the lungs, but another (and probably by far the larger) part finds its way through the Ductus Arteriosus or Ductus Botalli into the descending Aorta, mingling with the arterial current which that vessel previously conveyed, and passing thus to the trunk and lower extremities. Hence the head and superior extremities, whose development is required to be in advance of that of the lower, are supplied with blood nearly as pure as that which returns from the placenta; whilst the rest of the body receives a mixture of this with what has previously circulated through the system. In the course of the circulation the blood is returned by the umbilical arteries to the placenta,

* "Edinb. Med. and Surg. Journal," vol. xliii.; and "Anat., Physiol., and Pathol. Researches," chap. ix.

where it gives off its carbonic acid and receives oxygen from the maternal blood. Dr. Zuntz* finds that the fœtus has less hæmoglobin (an average of 3·6 per cent.) and less available oxygen than the adult. He also shows that if the mother be asphyxiated, the fœtal blood actually loses oxygen during its passage through the placenta, as is shown by the darker colour of the blood which flows along the umbilical vein under such circumstances. At birth the course of the current is entirely changed by the cessation of the circulation through the Placenta, and by the enormous increase in the quantity transmitted to the Lungs, which takes place immediately on the first inspiration; the Ductus Venosus and the Ductus Arteriosus soon shrivel into ligaments; the Foramen Ovale becomes closed from below upwards by its valve; and the circulation which was before carried on upon the plan of that of the higher Reptiles, now becomes that of the complete Bird or Mammal.† It is by no means unfrequent, however, for some arrest of development to prevent the completion of these changes; and various malformations, involving an imperfect discharge of the function, may hence result. From the above description it is obvious that the chief propelling power in the circulation of the Fœtus is the right heart; the force of the left heart being chiefly spent in propelling a due supply of blood to the head and upper extremities; and an interesting observation of Langer‡ is in accordance with this, for he has shown that the walls of the right ventricle in the fœtus are as thick as those of the left, whilst those of the right auricle are even thicker and more muscular than those of the left auricle. This condition lasts for some days after birth, when the left heart gradually attains the superiority in thickness which is usual in adults.

Fig. 352.

Embryo of *Dog*, 25 days after last copulation:—*a*, nostrils; *b*, *b*, eyes; *c*, first visceral arches, forming the lower jaw; *d*, *d*, second visceral arches; *e*, right auricle; *f*, left auricle; *g*, right ventricle; *h*, left ventricle; *i*, aortic bulb; *k*, *k*, liver, between the two lobes of which is seen the divided orifice of the omphalo-mesaraic vein; *l*, stomach; *m*, intestine, communicating with the umbilical vesicle *n*, *n*; *o*, *o*, corpora Wolffiana; *p*, allantois; *q*, *q*, anterior extremities; *r*, *r*, posterior extremities.

743. The *Alimentary Canal* has been shown (§ 736) to have its origin in the blastodermic vesicle; being a portion pinched off (as it were) by the infolding of the splanchnopleure from that part of it which is just beneath the spinal column of the embryo, whilst the remainder, which is at that time the largest part of it, forms the vitelline or umbilical vesicle. From the folding in of the splanchnopleure its hypoblastic portion comes to line the tube, and from it is formed the epithelium of the intestine, whilst the mesoblastic portion, lying outside, gives rise to the submucous layers, muscles, glands, &c. In its earliest form it is merely part of a long narrow tube (Fig. 352, *m*), nearly straight, and communicating with the umbilical vesicle (*n*, *n*)

at about the middle of its length; it may be regarded as composed of three divisions, an upper, middle, and a lower. The upper portion, corresponding to the foregut, comprises the Pharynx, œsophagus, stomach, and duodenum; the middle or midgut is equivalent to the rest of the small intestine and to the upper part of the colon; the lowest part or hindgut forms the lower part of the colon and the rectum. At first, neither mouth nor anus exists. The mouth is formed by an involution of the facial portion of the embryo, and is therefore lined at first with epiblast; it appears about the sixth week. The anus is a longitudinal slit which opens below the external organs of generation about a week after the appearance of the mouth. The tube gradually manifests a distinction into its special parts, œsophagus, stomach, small intestine, and large intestine; and the first change in its position occurs in the stomach, which, originally disposed in the line of the body, afterwards takes an oblique direction. The curves of the large and small intestine present themselves at a later period. It is at the lower part of the small intestine, near its termination in the large, that the entrance of the vitelline duct persists; and a remnant of this canal is not unfrequently preserved throughout life, in the form of a small pouch or diverticulum from that part of the intestine. Villi appear in both the large and small intestine about the fourth month, but they soon become rudimentary in the large intestine, in which they can no longer be distinguished after the eighth month. In the small intestines the villi are permanent.

744. In immediate connection with the intestinal tube we find the first rudiments of the *Liver*, which is formed in the chick at about the 60th hour of incubation by the thickening of the meso- and hypoblastic cells in the wall of the duodenum, at the spot at which the hepatic duct is subsequently to discharge itself. This thickening (Fig. 353), which is situated a little behind the heart, soon presents two diverticula which embrace the meatus venosus or united trunk of the omphalo-mesaraic veins, which, as it passes between them, exhibits numerous small bulgings. Towards the end of the third day, according to Foster and Balfour, there may be observed in the greatly thickened mesoblastic investment of each diverticulum a number of solid cylindrical masses of cells which are apparently outgrowths from the hypoblast of the diverticulum. These unite and form a network; the mesoblast contained in the meshes becoming at the same time largely converted into blood-vessels. In addition to this network of solid hypoblastic cylinders, the diverticula also send out hollow processes lined with hypoblast. On the fourth day the two masses meet beneath the meatus venosus. The blood-vessels of the mesoblast enter into communication with the meatus venosus. "It may soon be observed that in those vessels which are connected with the posterior part of the liver, the stream of blood is directed from the meatus venosus into the network of the liver, and they are therefore known as the venæ advehentes. In those connected with the anterior part—the venæ revehentes—the reverse is the case; here the blood flows from the liver into the meatus venosus. The thick network of solid cylinders represents the hepatic parenchyma of the adult liver, while the hollow processes of the

Fig. 353.

Origin of the *Liver* from the intestinal wall in the embryo of the Fowl, on the fourth day of incubation: —*a*, heart; *b*, intestine; *c*, everted portion giving origin to liver; *d*, liver; *e*, portion of vitelline vesicle.

diverticula are the rudiments of the biliary ducts."* As this is going on, the hepatic mass is gradually removed to a distance from the wall of the alimentary canal; and the cæcum is narrowed and lengthened, so as to become a mere connecting pedicle, forming, in fact, the main trunk of the hepatic duct.—In the Human embryo, the formation of the Liver begins at about the third week of intra-uterine existence; the organ is from the first of very large size, when compared with that of the body; and between the third and fifth weeks it is one-half the weight of the entire embryo. It is at that period divided into several lobes. By the third lunar month the liver extends nearly to the pelvis, and almost fills the abdomen; the right side now begins to gain upon the left; the gall-bladder makes its first appearance at this time. The subsequent changes chiefly consist in the consolidation of the viscus, and the diminution of its proportional size. Up to the period of birth, however, the bulk of the liver, relatively to that of the entire body, is much greater than in the adult; the proportion being as 1 to 18 or 20 in the new-born child, whilst it is about 1 to 36 in the adult; and the difference between the right and left lobes is still inconsiderable. During the first year of extra-uterine life, however, a great change takes place; the right lobe increases a little or remains stationary, whilst the left lobe undergoes an absolute diminution, being reduced nearly one-half; and as, during the same period, the bulk of the rest of the body has been rapidly increasing, the proportion is much more reduced during that period than in any subsequent one of the same length. According to Meckel the liver of the newly-born infant weighs one-fourth heavier than that of a child eight or ten months old; and as the weight of the whole body is more than doubled during the same time, it is obvious that the change in the proportion of the two must be principally effected at this epoch. The liver seems to be engaged during fœtal life in the depuration of the blood (as appears from the accumulation of *meconium*, which is chiefly altered bile mixed with the secretion of the alimentary canal and a few desquamated epithelial cells in the intestinal canal at birth); but at the same time it is serving as a blood-making organ, containing many free nuclei and protoplasmic masses,† and this is probably its principal function before birth. The general history which has just been given of the development of the Liver, seems equally applicable to the other glands that are evolved from the mesoblast and hypoblast forming the parietes of the Alimentary canal, such as the *Pancreas*, mucous and Peptic glands;‡ as well as the salivary glands, although they are developed from the mesoblast and epiblast, since they all seem to commence in little masses of cells, formed by an increased development, at certain spots, of the layers of blastema which originally constituted its wall; and whilst the cells of the mesoblast give origin to the proper vesicles of each gland, its ducts and tubuli, those of the hypoblast or epiblast form their epithelial lining.—The development of the *Spleen* and of the *Adrenal*, *Thymus*, and *Thyroid* bodies, have been already described.

745. The *Lungs* are also developed from the mesoblast in immediate relation with the upper part of the Alimentary canal, their rudiments, which form the primary bronchi, shooting-forth as a pair of bud-like processes (Fig. 354, *a*) from the under or anterior surface of the œsophageal portion. These were originally and correctly described by Von Baer as hollow, and as

* Foster and Balfour's "Elements of Embryology" (1874), p. 132.

† Schenk, "Centralblatt," 1869, p. 865.

being in reality *diverticula* from the tube itself. Like it, they consist of mesoblast lined by hypoblast. They gradually increase in size, and frequently divide, extending downwards by the multiplication of their component cells in that direction; and their cavities at first communicate with the pharynx by separate apertures; these, however, as the channels are elongated into tubes, coalesce to form the trachea, and the pulmonary organs become removed to a distance from their point of exit (Fig. 354, *b*).—The first appearance of the Lungs in the Chick takes place towards the close of the third day, and in the Human embryo at about the sixth week. Their surface soon becomes studded with numerous little wart-like projections, which are caused by the formation of corresponding enlargements of their cavity; these enlargements speedily become prolonged, and develop corresponding bud-like enlargements from their sides; and in this manner the form of the organs is gradually changed, a progressive increase in their bulk taking place from above downwards, in consequence of the extension of the bronchial ramifications of the single tube at the apex. At the same time, however, a corresponding increase in the amount of the parenchymatous tissue of the lung is taking place; for this is deposited in all the interstices between the bronchial ramifications, and might be compared with the soil filling up the spaces amongst the roots of a tree. It is in this parenchyma that the pulmonary vessels are distributed; and the portion of it which extends beyond the terminations of the bronchial tubes seems to act as the nidus for their further extension. It can be easily shown that, up to a late period of the development of the lungs the dilated terminations of the bronchi constitute the only air cells (Fig. 354, *c*); but, as already mentioned, the parenchyma subsequently has additional cavities formed within it.—It is a fact of some interest, as an example of the tendency of certain diseased conditions to produce a return to forms which are natural to the fœtal organism, or which present themselves in other animals, that up to a late period in the development of the Human Embryo, the lungs do not nearly fill the cavity of the chest, and the pleura of each side contains a good deal of serous fluid.

Fig. 354.

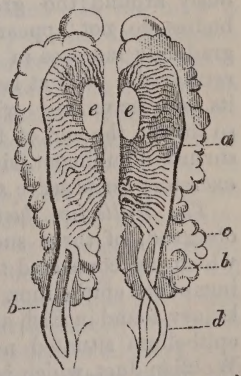
746. The embryological development of the *Urinary* organs in Vertebrate animals is a subject of peculiar interest;* owing to the correspondence which may be traced between the transitory forms they present in the higher classes, and their permanent condition in the lower. In this respect there is an evident analogy with the Respiratory system. The first appearance of any-

* Special attention has recently been devoted to this subject, more especially by Dr. Gasser, "Arch. f. Mikr. Anat.," vol. xiv. An abstract of this Paper will be found in the "Quarterly Journal of Microscop. Sci.," vol. xix. (1877), p. 16. Prof. Semper, "Centralbl. f. d. med. Wiss.," 1874, pp. 544, 817, 927 and 945. Dr. Alex. Schultz, *ibid.* 1874, p. 804; Dr. Sernoff, *ibid.* 1874, p. 481; an abstract of these Papers will also be found in the same Journal, vol. xv. (1875), pp. 91–94. Mr. Balfour 'On the Origin and History of the Urino-genital Organs of Vertebrates,' Humphry and Turner's "Journal of Anat. and Physiol.," vol. x. (1876), p. 17, where a bibliography of the subject up to that year is given; "Monograph of Elasmobranch Fishes;" 'On the existence of a head kidney in the embryo chick, and on certain points in the development of the Müllerian duct,' "Quart. Journ. Micros. Sci.," vol. xix. (1879), p. 1; Mr. Adam Sedgwick, 'Development of the kidney in its relation to the Wolffian body,' *ibid.*, vol. xx. (1880), pp. 146 and 373. From the latter Papers most of the statements in the text have been taken.

thing resembling a Urinary apparatus in the Chick is seen, according to Dr. Gasser, in an embryo with eight protovertebræ, as a slight projection from the intermediate cell mass towards the epiblast in the region of the three hindermost protovertebræ. In the next stage, with eleven protovertebræ, the solid rudiment of what will afterwards become a duct extends from the fifth to the eleventh protovertebra, from the eighth to the eleventh protovertebra it lies between the epiblast and mesoblast, and is quite distinct from both. In the region of the fifth protovertebra, where the duct was originally continuous with the mesoblast, it has now become free, but is still attached in the region of the sixth to the eighth protovertebra. In an embryo with fourteen protovertebræ the duct extends from the fourth to the fourteenth protovertebra, and is now free between the epiblast and mesoblast along its whole extent. It is still for the most part solid, though perhaps a small lumen is present in its centre. In the succeeding stages the lumen of the duct, which is formed by the cells assuming a radiating arrangement, and separating at their common point of junction, extends backwards and forwards. The duct itself also passes inwards till it acquires its final position close to the peritoneal epithelium, at the same time its hinder end elongates till it comes into connection with the cloacal section of the hind gut. On the second half of the third day, therefore, the duct appears as a long canal, extending on each side of the spinal column, from the region of the heart, towards the allantois (Fig. 352, *o*, *o*), seen also in transverse section in Fig. 339, *ung* ; on the sides of this are a series of elevations and depressions, indicative of the incipient development of cæca. On the fourth day the *Corpora Wolffiana*, as they are then termed, are distinctly recognized as composed of a series of cæcal appendages, which are attached along the whole course of the first-mentioned canal, opening into its outer side (Fig. 355, *a*). On the fifth day these appendages are convoluted, and the body which they form acquires increased breadth and thickness; they evidently then possess a secreting function, and the fluid which they separate is poured by their long straight canals (*b*, *b*) into the two horns of the cloaca; and between their component shut sacs numbers of small points appear, which consist of little clusters of convoluted vessels, exactly analogous to the Corpora Malpighiana of the true kidney. Mr. Sedgwick states that the Wolffian body develops first of all in the front portion of the embryo, and that it then passes gradually backwards. The tubules of the Wolffian body do not develop from serial involutions of the peritoneal epithelium, but from the cells of the intermediate cell mass, independently of the Wolffian duct, into which they only open at a later date. The cell mass is a group of cells stretching between the protovertebræ and the dorsal inner angle of the body cavity (Fig. 339); it is at first continuous with the peritoneal epithelium, but afterwards breaks away from it, and forms a cellular blastema, which lies just internal to the Wolffian duct, and may be called the Wolffian blastema. The Wolffian blastema almost directly breaks up into certain structures which represent the first rudiments of the Wolffian tubules. These tubules are formed by the appearance, just internal to the Wolffian duct, of a number of vesicles which are either oval or circular, and are lined by columnar cells. From the inner and dorsal wall of the vesicles a glomerulus

Fig. 355.



State of the *Urinary* and *Genital Apparatus* in the early embryo of the Bird :—*a*, corpora Wolffiana; *b*, *b*, their excretory ducts ; *c*, kidneys; *d*, ureter; *e*, *e*, testes.

is afterwards developed, the whole structure grows enormously, and gives rise to the Malpighian body, and to the complicated coils of the later Wolffian tubule, which opens into the Wolffian duct. At a slightly later stage, secondary, tertiary, &c., tubules arise in a similar manner, from small masses of cells, each being placed dorsally to the last formed tubule.

The Wolffian bodies remain as the permanent urinary organs of Fishes; but in the higher Vertebrata they give place to *the true Kidneys*, the development of which commences in the Chick about the sixth day, only a small part persisting in the male as the epididymis. The Wolffian blastema, already mentioned, gives rise, for a certain distance, to the Wolffian tubules. In the Chick this extends as far back as the thirtieth protovertebra, but beyond this point—*i.e.*, from the thirty-first to the thirty-fourth segments inclusive—the blastema gives origin to the epithelium of the permanent kidneys, and it is therefore known between these limits as the kidney blastema. During, and for some time after, the formation of the Wolffian body, the kidney blastema remains perfectly quiescent. About the 80-100th hour, however, the ureter or duct of the permanent kidney arises as a growth forward from the dorsal border of the enlarged end of the Wolffian duct. The kidney blastema is now found close to the body cavity, lying dorsally to its former position, just internal to the dorsal extremity of the dilated Wolffian duct. At the end of the fifth day the ureter acquires a greater development, and overlaps the hind end of the Wolffian body; the kidney blastema becoming completely separated from the Wolffian body, and investing the anterior extremity of the ureter. By the seventh day the ureter, which is now a small duct lying just dorsal to the Wolffian body, and opening separately into the cloaca, has increased in length, and has become dilated at intervals, whilst the kidney blastema has collected round these dilatations. The dilatations put out tubules which burrow into the kidney blastema, which thereupon arranges itself most conspicuously around the growing extremities of the tubules. The Malpighian bodies do not appear distinctly till after the eighth day. As the kidneys gradually increase in size and advance in development, the Wolffian bodies retrograde, until at last only the anterior or so-called sexual portion persists, its tubules uniting with the seminiferous tubules to form the epididymis, so that at the end of fœtal life, the only vestige of them is to be found as a shrunken rudiment, situated (in the male) near the testes, to which their excretory ducts serve as the outlets, becoming the 'vasa deferentia.'

The Müllerian duct consists, at the earliest period at which it has been observed, of three successive open involutions of the peritoneal epithelium, which are connected together by more or less well-defined ridge-like thickenings of the epithelium. It corresponds, according to Mr. Balfour,* to the head kidney found in Fish and Amphibia, and it arises from that layer of thickened epithelium situated near the dorsal angle of the body cavity, close to the Wolffian duct, which is known as the germinal epithelium. The anterior of the three open grooves is simply a shallow groove in the thickest part of the germinal epithelium, and lies some little distance behind the front end of the Wolffian duct; its walls become gradually continued into a slight ridge-like thickening of the germinal epithelium, and the same description applies to the second and third grooves. At a later stage the ridges separating these grooves become better marked, and are perforated to form ducts connecting the adjacent grooves. At a still more advanced period of development the ridges become more or less completely detached from the peritoneal epithelium, and the whole head kidney then consists of a slightly convoluted duct, with at

* Op. cit. p. 2.

least three peritoneal openings, which is continued posteriorly into the Müllerian duct. Still later the head kidney atrophies, its two posterior openings vanish, and its anterior opening remains as the permanent opening of the Müllerian duct. These changes are usually accomplished between the 90th and 120th hours of incubation. The head kidney of the Chick possesses also a paired glomerulus similar in its structure to that found in the head kidney of the Amphibia. Before the head kidney has disappeared, the rudiment of the Müllerian duct consists of a solid rod of cells continuous with the third groove of the head kidney, and terminating by a fine point of about two cells, wedged in between the Wolffian duct and the germinal epithelium. When the atrophy of the head kidney is almost complete, the Müllerian duct extends nearly to the cloaca, and the lumen is continued close to its terminal point, the duct terminating by fusing with the walls of the Wolffian duct. At the close of the sixth day the Müllerian duct, as it passes backwards, is in contact with the wall of the Wolffian duct on one side and with the germinal epithelium on the other. It gradually dilates; the external wall of the Wolffian duct becomes greatly thickened, and pushed in at its middle part so as to touch the opposite wall of the duct and form a bay, in which the Müllerian duct lies. No well-defined line of separation can then be traced between the walls of the Wolffian and those of the Müllerian ducts, but between the two there is a narrow clear space traversed by an irregular network of fibres, in some of the meshes of which nuclei are present. The Müllerian duct ultimately opens separately, and above the Wolffian duct, into the cloaca. If these observations be correct, it will be seen that the views previously held as to the origin of the Müllerian duct in a space between a portion of the thickened germinal epithelium and the Wolffian duct, but quite independently of both of them, is no longer tenable. The duct of Müller on the right side (in the Fowl, the left with the corresponding ovary disappearing) is never closed-in in front, and remains in the female as the oviduct. In the male it is almost entirely obliterated on both sides. The history of the development of the Urinary organs in the human embryo seems to correspond closely with the foregoing. The Wolffian bodies begin to appear towards the end of the first month; and it is in the course of the 7th week that the true Kidneys first present themselves. When at their greatest development, the Corpora Wolffiana are the most vascular parts of the body next to the liver; four or five branches from the aorta are distributed to each, and two veins are returned from each to the vena cava. The upper arteries and their corresponding veins are afterwards converted into the Renal or emulgent vessels; and the lower into the Spermatic vessels. From the beginning of the 3rd month, a diminution takes place in the size of the Wolffian bodies, *pari passu* with the increase of the Kidneys; and at the time of birth scarcely any traces of the former can be found. At the end of the 3rd month, the Kidneys consist of seven or eight lobes, the future pyramids; their excretory ducts still remain in the canal, the *sinus urogenitalis*, which receives those of the Wolffian bodies (subsequently to become the vasa deferentia), and of the Fallopian tubes;* and this opens, with the rectum, into a sort of *Cloaca*, analogous to

* Although it has been usually considered that the Vasa Deferentia of the male and the Fallopian tubes of the female are homologous organs, yet this is not really the case; for the former are derived from the excretory ducts of the Wolffian bodies, whilst the latter are independent formations, which are found to co-exist with seminal ducts at an early period of development, alike in male and in female embryos. (See Kobelt, "Der Nebeneierstock des Weibes," Heidelberg, 1847.) The ducts of the Wolffian bodies, although subsequently disappearing in the females of most Mammals, remain permanent as 'Gaertner's canals' in the female Ruminants and Pig.

that which is permanent in the oviparous Vertebrata. The Kidneys are at this time covered by the Adrenals, which equal them in size; about the 6th month, however, these have decreased, whilst the kidneys have increased, so that their proportional weight is as 1 to $2\frac{1}{2}$. At birth the weight of the Kidneys is about three times that of the Adrenals, and they bear to the whole body the proportion of 1 to 80; in the adult, however, they are no more than 1 to 240. The lobulated appearance of the kidney gradually disappears; partly in consequence of the condensation of the areolar tissue which connects its different portions, and partly through the development of additional tubuli in the interstices.—*The Urinary Bladder* is formed quite independently of the secreting apparatus, being an enlargement of the lower portion of the Allantois, a constricted part of the same fœtal organ, forming the commencement of the urethra in the male, and the whole length of that canal in the female (§ 748).

747. The essential parts of the *Generative Apparatus*—namely, the Testes in the male, and the Ovaria in the female—are first developed in such immediate proximity with the Corpora Wolffiana (Fig. 355, *e*, *e*), that they have been supposed to sprout forth from them; this, however, is not really the case, as they have an independent origin in the intermediate mass of mesoblastic blastema (termed by Foster and Balfour the *genital ridge*), from which the Wolffian body and Kidneys have successively been differentiated. They make their first appearance in the Chick, as delicate striæ on the Wolffian bodies, about the fourth day; at which period no difference can be detected between the Testes and the Ovaria, which originate in precisely the same manner. The superficial cells proceeding originally from the epiblast acquire special characters, and, as already described (§ 696), become invested and enclosed by an outgrowth of the stroma of the ovary, and constitute the primordial ova. In the Human embryo, the rudiments of the sexual organs—whether testes or ovaria—first present themselves soon after the kidneys make their appearance, that is, towards the end of the 7th week. They are originally much prolonged, and seem to consist of a kind of soft homogeneous blastema, in which the structure characteristic of each organ subsequently develops itself. The *Testis* gradually assumes its permanent form; the epididymis appears in the 10th week; and the gubernaculum (a membranous process from the filamentous tissue of the scrotum, analogous to the round ligament arising from the labium, and attached to the ovary in the female), which is originally attached to the vas deferens, gradually fixes itself to the lower end of the testis or epididymis. The Wolffian ducts remain as the vasa deferentia of the male (§ 746), the vesiculæ seminales being developed as diverticula from their posterior extremity. The Testes begin to descend at about the middle of pregnancy; at the seventh month they reach the inner ring; in the eighth they enter the passage; and in the ninth they usually descend into the scrotum. The cause of this descent is not very clear: it can scarcely be due merely, as some have supposed, to the contraction of the gubernaculum; since that does not contain any muscular structure until after the lowering of the testes has commenced. It is well known that the testes are not always found in the scrotum at the time of birth, even at the full period. Upon an examination of 97 new-born infants, Wrisberg found both testes in the scrotum in 67, one or both in the canal in 17, in 8 one testis in the abdomen, and in 3 both testes within the cavity. Sometimes one or both testes remain in the abdomen during the whole of life; but this circumstance does not seem to impair their function.* This condition is natural, indeed, in the Ram.

* A case occurred within the Author's knowledge, in which both testes remained in the abdomen until the tenth year, and then descended.

According to Waldeyer,* the first appearance of *the ovary* consists of a thickened germ epithelium, investing a small vascular outgrowth, rich in cells, which projects from the interstitial tissue of the Wolffian body on its median side, and which subsequently forms the stroma of the ovary. The germ epithelium itself is derived by direct proliferation from the columnar cells which invest the median side or surface of the Wolffian body, and which are continuous with the layer of columnar cells lining the pleuro-peritoneal cavity of the embryo in the early stages of development. In a fœtus of 7½ months, Dr. Foulis found that the germ epithelium thus formed consists of columnar cells lying side by side, and so arranged as to form an investment to the whole ovary. The germ epithelium rests upon a thin irregular layer of connective tissue, which forms part of the general stroma of the ovary, and is the forerunner of the tunica albicans. The ovary at this period consists of a stroma attached to a stalk of fibro-vascular tissue, which is covered by an epithelium continuous on the one side with the peritoneal epithelium, and on the other with the germ epithelium. If the germ epithelium be examined at this period, the cells which compose it will be found to consist of nucleated masses of protoplasm, varying in size, at first somewhat columnar, afterwards oval or spherical. As development proceeds, the nucleus of one of the larger germinal epithelium cells swells up, and becomes first oval, then spherical, and marked with a double contoured line, within which one or two nucleoli are generally seen, whilst around it is produced gradually that protoplasm which assumes such dimensions in this the primordial ovum. In contact with the primordial ova are small fusiform cells, some of which appear to have grown up amongst the germ epithelium from the stratum of connective tissue upon which this epithelium rests. The primordial ova are developed in groups, each group becoming enclosed in the connective tissue of which the stroma of the ovary is composed. After the cells have been included in meshes of the stroma, they increase in number and size, and thus results the formation of those large egg-clusters which are found under the germinal epithelium in all parts of the ovary. In each egg-cluster, however, certain cells are found to be much farther advanced than others, and these alone reach maturity, the smaller cells, although potentially ova, abort and disappear, some probably forming nourishment for the more vigorous and healthy ones, whilst others, as will be afterwards shown, give rise to the follicular epithelium. According to Balfour, whose observations are supported by Klein, the primordial ova are formed by a segregation taking place in the contents of the nucleus within the membrane, the granular contents passing to one side, where they form an irregular mass, whilst the remaining space within the membrane is perfectly clear. The granular mass gradually develops itself into a beautiful reticulum with two or three highly refracting nucleoli, one of which eventually becomes the largest and forms the germinal spot. At the same time the body of the ovum becomes slightly granular. While the above changes, more especially those involving the nucleus, are taking place, the protoplasm of two or more ova may fuse together, and multi-nucleated masses may thus be formed. The whole of such a multi-

* Foulis, 'On the Development of the Ova and Structure of the Ovary in Man and other Mammalia,' "Trans. Roy. Soc. Ed.," vol. xxvii., from whose monograph we take most of the account given in the text; and also in Humphry and Turner's "Journal," vol. xiii. (1879), p. 352, 'On the structure of the Ovary.' For recent Memoirs on the subject, see Balfour's Paper 'On the Structure and Development of the Vertebrate Ovary,' in the "Quart. Journ. Micros. Sci.," vol. xviii. (1878), p. 418, an abstract of which will be found in Klein and Noble's "Atlas of Histology," 1880, p. 291.

nucleated mass is sometimes connected into a single ovum, in which case all the nuclei except one, atrophy; in other cases, the mass gives rise by subsequent division to two or more ova, each with a single germinal vesicle. At a later period than the one above described, the stroma of the ovary grows into the egg-clusters, and separates the primordial ova, enclosing each in a separate capsule. The first *Graafian follicle* is thus formed, consisting at this stage of a young ovum, which completely fills the follicle of stroma surrounding it. Some of the smaller cells which accompanied the larger ones in the egg-clusters, and which like them originated from the cells of the germinal vesicle, surround the primordial ovum, and give rise to the follicular epithelium.* The cells constituting this epithelium are flat, circular, or oval plates, which appear to be fusiform in section, and which at first form a single layer surrounding the ovum as with a wreath. From these cells is derived the *membrana granulosa;* at first a single layer, it soon consists of several layers, owing to the rapid multiplication of the first cells by fission. At a later stage, some of the cells in the intermediate layer break down and dissolve. In this way a space is formed, which is afterwards filled with the *liquor folliculi.* This solution of cells does not take place throughout the whole circle of the ovum, which therefore remains attached at one point to the wall of the follicle, and from this point a layer of the membrana granulosa or follicular epithelium extends over the ovum as the *discus proligerus. The zona pellucida* or *vitelline membrane* is formed by a hardening of the outer portion of the yolk, and is not, as was supposed by Reichert, Pflüger, and Waldeyer, a product of the follicular epithelium. At birth, the most advanced ova are met with deep in the ovary. After birth, the cells of the germinal epithelium gradually become smaller and lose their columnar form, so that at the age of six years they present the appearance of small flattened hexagonal cells, which can readily be stripped off the surface of the ovary. After the age of two and a half years the ova are formed in the human ovary.—The *Ovary* undergoes much less alteration in its position than do the testes. Its efferent canal (which, as just stated, is *not* the representative of the vas deferens of the male, but is the duct of Müller) remains detached from it, presents a free terminal aperture, and constitutes the Fallopian tube. The *uterus* and *vagina* are formed by the coalescence of the lower portions of the Müllerian ducts, the upper portion of the ducts remaining permanently as the Fallopian tubes. By the subsequent absorption of the septum in the coalesced portions, the genital canal is formed. In the Female, this canal increases in size; and a marked separation is established about the fifth or sixth month by means of a transvere dismemberment between its lower or vaginal portion and its upper or uterine portion. The former opens into the uro-genital sinus, it commences at the vestibule, and receives the terminations of the urethra and of the Wolffian ducts, remaining permanently unclosed. In the Male, on the other hand, no such transverse dismemberment of the genital canal ever takes place; it makes no advance in development, and diminishes in relative size; so that at the period of fœtal maturity it is only discoverable as the *vesicula prostatica,* which has been supposed until recently to be an appendage to the prostate gland. A transverse con-

* Foulis is opposed to Waldeyer, Balfour, and other observers on this point, for he believes that "small fusiform cells belonging to the stroma of the ovary, and situated in the wall of the follicle, indent the protoplasm of the young ovum as it lies in its capsule," and that in a ripe Graafian follicle the stroma cells outside the membrana propria folliculi become converted into cells exactly similar to the true follicle cells, so that it is possible to trace the ordinary stroma cells outside the follicle through all stages of development into cells exactly resembling the follicle cells. This last observation affords to Dr. Foulis the most conclusive proof of the origin of the follicle cells from the ordinary cells of the stroma.

striction in this canal marks out its vaginal from its uterine portion; the former having exactly the same relation as in the female to the terminations of the urethra and of the Wolffian ducts (vasa deferentia) in the 'uro-genital sinus,' which is subsequently closed in, however, so as apparently to form a continuation of the urethral canal; and the latter, in those Mammals whose females have a 'uterus bicornis,' exhibiting a like divarication into two lateral halves.*

748. The history of the development of the *external Organs of Generation* in the two sexes presents matter of great interest, from the light which is thrown by a knowledge of it upon the malformations of these organs, which are among the most common of all departures from the normal type of Human organization.—Not only is the distinction of sexes altogether wanting at first, but the conformation of the external parts of the apparatus is originally the same in Man and the higher Mammalia as it permanently is in the Oviparous Vertebrata. For, about the fifth or sixth week of embryonic life, the opening of a *cloaca*, which is in connection with the sac of the allantois, may be seen externally, which receives the termination of the intestinal canal, the ureters, and the efferent ducts of the sexual organs; but at the tenth or eleventh week the anal aperture is separated from that of the genito-urinary canal, or 'uro-genital sinus,' by the development of a transverse band; and the uro-genital sinus itself is gradually separated by a like process of division into a 'pars urinaria' and a 'pars genitalis,' the former of which, extending towards the urachus, is converted into the urinary bladder. A partial representation of this phase of development is found in the permanent condition of the Struthious Birds and of the Implacental Mammalia. The external opening of this canal is soon observed to be bounded by two folds of skin, the rudiments of the labia majora in the female, and of the two halves of the scrotum in the male; whilst between and in front of these there is formed, as a bud from the anterior extremity of the pars genitalis, an erectile body, surmounted by a gland, and cleft or furrowed along its under surface. This body in the female is retracted into the genito-urinary canal, and becomes the clitoris, whilst the margins of its furrow are converted into the nymphæ or labia minora; and these bound the 'atrium vaginæ' or 'vestibule,' which receives the orifices of the urethra, of the vagina, and of Gaertner's canals when they are present. In the male, on the other hand, this sinus is nearly closed-in at a very early period, by the adhesion of the two folds of integument which bound it, forming that portion of the genito-urinary canal (improperly termed the 'urethra') which receives the orifices of the vesical or true urethra, of the genital sinus (vesicula prostatica), and of the vasa deferentia; the erectile body increases in prominence, and becomes the penis, whilst the margins of the furrow at its under surface unite (at about the fourteenth week), to form the anterior continuation of the contracted genito-urinary canal, which is commonly termed the spongy portion of the urethra. "In connection with the anterior and now distinct compartment of the cloaca or uro-genital sinus, and close to the junction of the latter with the base of the genital member, two glands are developed in each sex. These are the *glands of Bartholini* in the female, and those *of Cowper* in the male; opening as these glands do close to the base of the genital member, they form landmarks of first-rate importance in the determination of homologous parts of the uro-genital sinus, which

* See Prof. E. Weber's "Zusätze zur Lehre vom Baue und den Verrichtungen der Geschlechtsorgane," Leipzig, 1846; Dr. Leuckart's Art. 'Vesicula Prostatica' in "Cyclop. of Anat. and Physiol.," vol. iv.; and Prof. Watson 'On the Homologies of the Sexual Organs,' Humphry and Turner's "Journal," vol. xiv. (1879), p. 50.

differs widely in appearance in the two sexes. It will thus be found that the portion of the male uro-genital canal which intervenes between the point of entrance of the Wolffian ducts and the glands of Cowper must be homologous with that portion which in the female intervenes between the entrance of the Müllerian ducts and the glands of Bartholini. In other words, the short and wide vestibule of the human female must be homologous with the elongated and narrow lower half of the prostatic *plus* the membranous urethra in the male. Similarly, the genital members of the two sexes are strictly homologous, differing only in size. The margins of the lower or grooved surface remain apart in the female to form the vaginal bulbs, whilst in the male they coalesce to form the middle line, and complete the spongy portion of the urethra. The spongy portion of the urethra has therefore no representative in the human female. Finally, the labia majora are evidently homologous with the two halves of the scrotum."* The following Table, compiled from Banks,† Watson, and Allen Thomson,‡ gives clearly the origin and homologies of the several parts of the urino-genital system in the two sexes:—

I. COMMON BLASTEMA OF REPRODUCTIVE ORGANS.

Female.	*Embryonal.*	*Male.*
OVARY		BODY OF TESTICLE.
Furnishes the *ovigerms* and remains on the surface.	(1) Germ epithelial covering	Disappears and is replaced by serous covering of the tunica vaginalis.
Forms the *stroma* of the ovary and the Graafian follicles.	(2) Deeper blastema.	Forms glandular *seminal tubes* of testis.

II. WOLFFIAN BODIES.

Transverse tubes of *epoophoron*, or organ of Rosenmüller (parovarium).	(1) Upper tubular non-glomerular part.	*Vasa efferentia* and conivasculosi of the epididymis.
Paroophoron (Wald.)	(2) Lower glomerular part (primordial kidneys).	*Paradidymis* (Wald.) organ of Giraldès and vasa aberrantia.
Round ligament of the uterus.	(3) Ligament of the Wolffian body.	*Gubernaculum testis.*

III. WOLFFIAN DUCTS.

Tube of epoophoron.	(1) Upper and middle parts.	Convoluted tube of the *epididymis.*
Ducts of Gaertner (in cow and pig).	(2) Lower part.	*Vasa deferentia* and vesiculæ seminales.

IV. MÜLLERIAN DUCTS.

Fimbriated abdominal opening and terminal and occasional hydatids.	(1) Upper extremity.	*Hydatid of Morgagni.*
Fallopian tubes.	(2) Middle part.	Occasional tubular prolongation of the uterus masculinus.
Vagina and uterus.	(3) Lower single or median part.	Uterus masculinus (vesicula prostatica).

* Prof. Watson, loc. cit., p. 66.

† Prize Thesis, Edinburgh, 1864, "On the Wolffian Bodies of the Fœtus, and their remains in the Adult, including the Development of the Generative System."

‡ Quain's "Anat." ed. 8, vol. ii. p. 826.

External Organs.

V. SINUS URO-GENITALIS.

In the Female.	*Common Embryonal.*	*In the Male.*
Tissue uniting female urethra and vagina.	Substance surrounding genital cord.	Prostate gland, muscular and glandular tissue.
Female urethra.	Upper part of urinary pedicle	Upper portion of prostatic urethra.
Ostium vaginæ. Hymen.	Confluence of urinary and genital parts.	Verumontanum.
Vestibule.	Lower part of urinary pedicle	Lower part of prostatic and membranous urethra.
Glands of Bartholini.	Blastema.	Glands of Cowper.
Crura and corpus clitoridis.	Corpora cavernosa.	Crura and corpus penis.
Glans clitoridis and vaginal bulbs.	Corpora spongiosa.	Glans penis and corpus spongiosum urethræ.
Labia majora.	Genital ridges.	Scrotum and raphe.
Labia minora.		Cutaneous covering of the urethra.

749. In a large proportion of cases of so-called *Hermaphrodism*,* there has been either a want of completeness in the development of the Male organs, so that they present a greater or less degree of resemblance to those of the female; or the developmental process has gone on to an abnormal extent in the Female organs, so that they come to present a certain degree of resemblance to those of the male.—One of the most common malformations of the *male* organ is 'hypospadias,' or an abnormal opening of the urethra at the base of the penis, arising from incompleteness in the closure of the edges of its original furrow. But when the developmental process has been checked at an early period, the uro-genital sinus may retain more nearly its original character, and may have a wide external opening beneath the root of the penis, so as to resemble the female vagina, whilst the penis is itself destitute of any trace of the urethral canal; in some of these cases, again, the testes have not descended into the scrotum; whilst the absence of beard, the shrillness of the voice, and the fulness of the mammæ, have contributed to impart a feminine character to these individuals, their male attributes, however, being determined by the *seminiferous* character of the essential organs, the testes.†—In the *female* organs, on the other hand, a greater or less degree of resemblance to those of the male may be produced by the enlargement of the clitoris, by its furrowing or complete perforation by the urethra, by the closure of the entrance of the vagina and the cohesion of the labia, so as to present a likeness to the unfissured perineum and scrotum of the male, by the descent of the ovaries through the inguinal ring into the position of the male testes, and by the imperfect development of the uterus and mammæ; with these abnormalities are usually associated roughness of the voice and growth of hair on the chin, and a psychical character more or less virile.—*True* Hermaphrodism, in which there is an absolute combination of the essential male and female organs in the same individual, is comparatively rare. It may occur under the forms of *lateral* hermaphrodism, in which there is a genuine ovary

* See upon this subject, Prof. Watson, loc. cit., p. 73; Sam. Wood, "Dublin Quart. Journ. Med. Sci.," vol. xlvi. (1868), p. 52; Wieland in Fleetwood Churchill's "Practical Treatise on the Diseases of Women," 2nd ed., Paris, 1874.

† The *vesicula prostatica* has presented an unusual development in some of these cases; see Prof. Weber (loc. cit.), and Prof. Theile's 'Account of a Case of Hypospadias,' in Müller's "Archiv," 1847.

on one side and a testis on the other, in which case the external organs are usually those of a hypospadic male; *transverse* hermaphrodism, in which the external and internal organs do not correspond, the former being male and the latter female, or *vice versâ*;—and *double* or *vertical* hermaphrodism, in which the proper organs characteristic of one sex have existed, with the addition of some of those of the other; this is the rarest of all, and it is not certain that the coexistence of testes and ovaria on the same side has ever been observed in the Human species.*

750. We have now to follow the course of the development of the principal organs of *Animal* life; and shall first notice that of the *Skeleton*.† The first differentiation of parts that occurs in the mesoblast of the blastodermic vesicle (Fig. 356), is the formation of a solid cartilaginous rod, termed the notochord or chorda dorsalis (*ch*) which extends throughout the whole length of the future vertebral column, and along the base of the cranium as far as the space between the auditory capsules, or even to that point which subsequently becomes the pituitary fossa. The origin of the Notochord is still a subject of doubt; according to Kölliker‡ it is developed in Rabbits, and also in Birds from the mesoblast, appearing at first near the head, and then growing backwards at the expense of the middle layer. This is the generally received theory upon the subject. Balfour,§ however, tracing out the development of the Elasmobranchs, finds that this structure is developed originally from the hypoblast, and that it only secondarily becomes mesoblastic. This view is also supported by certain observations of Hensen‖ in regard to the development of Mammalia, whilst the drawings of Kölliker¶ seem also to lend support to the theory. Mihalkovics** is inclined to refer the origin of the notochord in all animals to the epiblast, since he believes it to be an epithelial product. The chorda dorsalis is originally composed of nucleated cells, that in the first instance lie in contact with one another, but are soon separated by the development of intercellular substance or matrix, the whole being enclosed by a delicate sheath. The chorda dorsalis, though permanent in the lowest Fishes, is only a transitory structure in Man and all the higher Vertebrata. Soon after the laying down of this cartilaginous rod, the portion of the mesoblast which immediately surrounds it (*uwp*, Fig. 356, *uw*, Fig. 357) becomes detached; and in the portion so separated the first rudiments of the vertebræ appear in the form of cubical masses on each side of the chorda dorsalis. The vertebræ appear at first as two masses of mesoblast, forming the vertebral plates, which run without interruption along each side of the notochord. Very soon, however,

** "Arch. f. Mikros. Anat.," xi. p. 389 *et seq.*

the vertebral plates are broken up by transverse lines which appear at short intervals and divide them into the quadrilateral masses known as the proto-vertebræ from which are developed, not only the permanent vertebræ, but also the episkeletal muscles. The first pair of proto-vertebræ to appear in the chick correspond with the third or fourth pair of cervical vertebræ in the adult. More externally, the mesoblast, passing outwards and downwards, and forming what is known as the Ventral Lamina, subdivides into two by a split or fissure (Fig. 357, *sp*), which is the first indication of the the pleuro-peritoneal cavity, the external or parietal layer (*hpl*) joining with the epiblast to form the *somatopleure* or walls of the abdomen with their contained structures, and ultimately meeting on the median line and enclosing the abdominal cavity in the same way that the dorsal laminæ enclose the spinal cord. The inner layer unites with the hypoblast (*df*), and forms the *splanchnopleure*, and developes the muscular and fibrous layers of the intestinal canal, the innermost layer or hypoblast (*dd*) producing the proper epithelium of the ducts and portions of the parenchyma of the several glands connected with the intestine. At this period the primitive aortæ (*ao*) and the first urinary organs or Wolffian bodies (*uwh*) begin to be formed. These, as just stated, are developed in the tissue situated externally to the chorda dorsalis, constituting a portion of the mesoblast (*uw*, Fig. 357), which now becomes separate and distinct from the remainder. The cubical masses of cells which form the original proto-vertebræ split longitudinally to form the muscle plates, and an inner portion which gives origin to the vertebral column. Soon after this period these inner portions of mesoblast (*uw*) extend themselves so as to embrace the chorda dorsalis below and the spinal cord above; the part where the two sides unite above being called by Rathke the *membrana reuniens superior*, or membranous vertebral arch. A portion of the proto-vertebræ also insinuates itself between the chorda dorsalis and the spinal cord, so that the former is entirely invested by it, and a complete vertebral column is formed, though still only *membranous*, presenting two tubes, the one posterior, formed by the arches, and enclosing the spinal cord, the other anterior, investing the chorda dorsalis. The membranous vertebral column then undergoes a process of secondary segmentation.* The transparent lines, indicating the limits of the proto-vertebræ, disappear, so that the whole vertebral column becomes fused into a homogenous mass, whose division into vertebræ is only indicated by the series of ganglia. This fusion, which does not extend to the muscle plates, is quickly followed by a fresh segmentation, the resulting segments being the rudiments of the permanent vertebræ. The new segmentation, however, does not follow the lines of the earlier division, but passes between the ganglionic and the vertebral portions, in fact through the middle of each proto-vertebra. In consequence, each spinal ganglion and nerve is attached to the hind part of the permanent ver-

* Foster and Balfour, "Elements of Embryology," pp. 153, 154.

tebra, immediately preceding. Similarly, the rudiment of each vertebral arch covering in the axial tube, no longer springs from the hinder part of the proto-vertebra from which it is an outgrowth, but forms the front part of the permanent vertebra to which it henceforward belongs. Each permanent vertebra is therefore formed out of portions of two consecutive proto-vertebræ. At the time when the fusion takes place, the mesoblast, which, in the form of processes from the proto-vertebral bodies, surrounds and invests the notochord, has not only increased in mass, but has also become cartilaginous; so that, as Gegenbaur points out, there is in the chick for a short period on the fifth day a continuous and unsegmented investment of the notochord. In the mammalian embryo it commences about the 6th or 7th week of fœtal life, and rapidly extends over the bodies of the future vertebræ, so that already in the 8th week a complete cartilaginous column with the membranous intervertebral ligament is formed; the chorda dorsalis now becomes attenuated and begins to disappear in the bodies of the vertebræ (Fig. 358), whereas it still remains distinct in the Ligamenta intervertebralia, and consequently presents a moniliform appearance. The formation of cartilage takes place much more slowly in the vertebral arches, not being more advanced at the 8th week than is shown in Fig. 359; so that at this period the medulla spinalis and its ganglia are only covered by the membrana reuniens superior. The arches first meet and enclose the medulla in the dorsal region; in the 4th month this is completed throughout the column, and, except in the coccygeal region, where no arches are developed, the form of the future vertebræ, in which ossification has already commenced, is perfect. The development of the atlas is irregular, its body, which is originally traversed by the chorda dorsalis, as shown by Rathke and Robin, becoming connected, not with its proper arch, but with the body of the axis forming the odontoid process of this vertebra. The ossification of the vertebræ begins at the end of the 2nd or the beginning of the 3rd month, with three centres for each vertebra, one for the body and one for the arch on each side. These parts, however, do not unite till the second year after birth. Accessory centres of ossification are subsequently formed at the tips of the spinous and transverse processes, and in the form of thin leaves at the upper and lower surfaces of the bodies, which resemble the epiphyses of the long bones. The cartilages of the *ribs* do not develop at once in their whole length, but gradually from the spine towards the sternum. Their ossification proceeds contemporaneously with those of the vertebræ from one centre for each rib, the anterior extremities of the upper seven uniting together to form a broad cartilaginous band, which constitutes one lateral half of the *sternum*, the two halves subsequently uniting from above downwards.

The morphological relations of the several parts constituting the shoulder girdle in man appear, according to the investigations of Mr. Parker,* to be as follows. Beginning with the scapula, the thin epiphysial ossification running along the vertebral border is the supra-scapular bone, well shown as segmented from the scapula in the ray and sturgeon, and large, but not quite segmented off from the scapula proper in the frogs. The whole infra-spinous portion of the bone represents the scapula proper, forming the greater portion of the scapula of the bird, but best differentiated as a distinct bone in the iguana and turtle. The acromion process, with the whole of the spinous process, constitutes the meso-scapula, which is seen partly segmented from the body of the scapula in the pangolins, but is well shown also in the iguana. The neck of the bone and the articular facet forming the glenoid region have a separate internal ossification in the frog and toad. The coracoid process forms a large separate bone in the ovipara, and in monotremes, of which only the part corresponding to the head is developed in the human subject, which speedily coalesces with the other elements forming the scapula. The portion of bone around the coracoid notch, with the fore part of the supra-spinous fossa, is the pre-scapula. It is well seen as a distinct bar above the glenoid cavity in certain lizards, and exists as a separate bone, even in the cat. The cartilaginous extremities of the clavicle are remnants of a primary rod of cartilage developed independently of the clavicles. The outer or meso-scapular segment becomes attached to the acromion by fibrous tissue, and an imperfect synovial articulation. The inner segment divides into two, of which the outer portion becomes attached to the true clavicle, whilst the internal portion, corresponding to the omo-sternum (or so-called episternum) of frogs, becomes converted into fibro-cartilage. The clavicle itself is a parosteal bar which has grafted itself on a delicate rod of cartilage.†

751. In order to facilitate the comprehension of terms now very generally employed both in Human and Comparative Anatomy in regard to the parts of a vertebra, the following description is here appended. The complete *typical vertebra* (Fig. 360, A) essentially consists, according to Prof. Owen,‡ of the *centrum*, around which are arranged four arches enclosed by processes in connection with it—viz., superiorly, the *neural* arch, which encloses the neural axis, and is formed by a pair of 'neurapophyses' (*n*, *n*) and a neural spine (*ns*); inferiorly the *hæmal* arch, which is in like special relation with the centres of the circulation, but may be expanded around the Visceral cavity generally, and which is formed of a pair of 'hæmapophyses' (*h*, *h*) and the 'hæmal spine (*h s*) and two *lateral* arches, enclosing vascular canals, which are bounded by the 'diapophyses' (*d*, *d*) and the 'parapophyses' (*p*, *p*), and are completed by the 'pleurapophyses' (*pl*, *pl*). Of these elements, the centrum is the most constant; and next to these are the neural arches, which we find in every part of the vertebral column through which the neural axis passes, and which are enormously developed in the cranial segments, in accordance with the high development of their nervous mass. The hæmal arches are

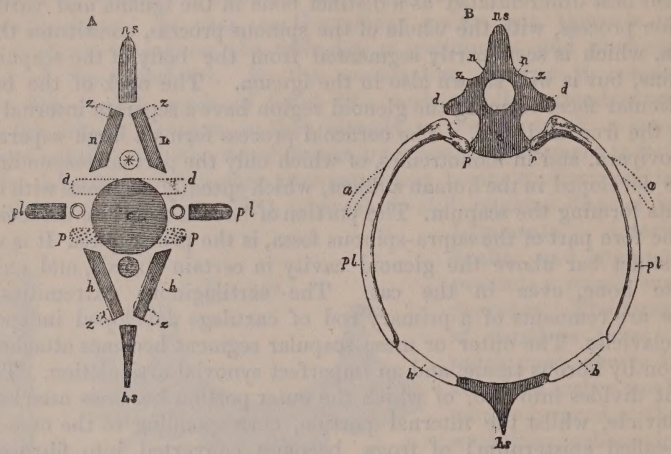
* See his important and extensive series of observations in the "Monograph on the Structure and Development of the Shoulder Girdle and Sternum in the Vertebrata," 1868, published by the Ray Society.

† Mr. Parker differentiates three kinds of ossification—"endostosis," occurring in the substance of hyaline cartilage; "ectostosis," when the bony deposit occurs in the almost structureless inner layer of the periosteum; and "parostosis," when the bone is formed in the skin, subcutaneous tissue, or in aponeuroses. Bones formed by parostosis are generally known as *membrane* or *splint* bones.

‡ See his "Archetype Skeleton," his "Lectures on Comparative Anatomy," and his "Discourse on the Nature of Limbs."

often almost entirely deficient, as in the cervical and lumbar vertebræ of Man and the Mammalia; but in the dorsal vertebræ they are very largely developed, and the elements of the lateral arches are brought into connection with them, so as to form the enclosure of the visceral cavity (Fig. 360, B). From the pleurapophyses are occasionally developed a pair of 'diverging

Fig. 360.



Elements of a *Vertebra* according to Prof. Owen:—A, ideal typical vertebra:—B, actual thoracic vertebra of a Bird:—*c*, centrum, giving-off *d*, *d*, the diapophyses, and *p*, *p*, the parapophyses; the neural arch, enclosing the spinal cord * is formed by *n*, *n*, the neurapophyses, and *n*, *s*, the neural spine; the hæmal arch, enclosing the great centres of the circulation, is formed by *h*, *h*, the hæmapophyses, and *h s*, the hæmal spine. From both the neurapophyses and hæmapophyses may be given-off the zygapophyses, *z*, *z*. The lateral arches, which may enclose the vertebral arteries, *o* o, are completed by the pleurapophyses, *pl*; these in B are bent downwards, so as to form part of the hæmal arch, and give-off the diverging appendages, *a*, *a*.

appendages' (*a*, *a*), which are well seen in the ribs of Birds; and these are considered by Prof. Owen to be the fundamental elements of the bones of the 'extremities' or 'limbs,' those of the anterior extremity being on his view the diverging appendages of the occipital vertebra, and those of the posterior extremity standing in the same relation to one of the sacral vertebræ. The number of the segments analogous to Vertebræ entering into the skull has been a subject of much discussion among those who adopt 'the vertebral theory' of its composition; but Prof. Owen agrees with Goethe and Oken (the original propounders of that theory) in fixing the number at *four*, which corresponds with the points of ossification, succeeding each other in a linear series, that, though absent in the earlier, are apparent in the latter stages of the development of the Encephalon, namely (proceeding from behind forwards), the Epencephalon, the Mesencephalon, the Prosencephalon, and the Rhinencephalon (Fig. 366); and also corresponding with the number of the nerves of special sense, the Auditory, Gustatory, Optic, and Olfactory, which issue from this part of the neural axis with the same segmental regularity that the ordinary sensori-motor nerves do elsewhere.

752. In the development of the *Skull* the same three stages may be traced as that in the Vertebral column—namely, the membranous, the cartilaginous, and the osseous; the result of the first two forming what is now called the Primordial Cranium. In the first stage, the membrane of the Cranium is formed of dense mesoblast from the anterior part of the proto-vertebral plates (*uwh*,

Fig. 357), which shoot forwards in front of the pointed extremity of the Chorda dorsalis or Notochord, arch upwards, and ultimately form a case for the brain.* An essential difference from those which, as we have just now seen, enclose the Spinal Cord, is however already very visible, in the perfect continuity and absence of any trace of segmentation in the basal mass. The form assumed by this deposit at a very early period is here diagrammatically shown (Fig. 361), *c* representing the atlas, or last segment of the true vertebral column, formed round the notochord, *a*, which terminates at the point *g*, where the pituitary body subsequently appears. In front of the atlas *c*, and also, like it, surrounding the notochord, a large quantity of blastema is laid down, which forms the investing mass, and to which is attached anteriorly a pair of cartilaginous rods, *g*, termed the trabeculæ cranii, that separate to enclose the pituitary fossa, and reunite in front of it to form a solid mass, the naso-frontal process which ultimately gives rise to the ali-nasal cartilages; owing to the cranial flexure, the trabeculæ at first lie in a plane different from the investing mass. From the margins of this great basal mass of the primordial cranium, a membranous investment rises up to cover the intra-cranial nervous centres. This membranous cranium, which accurately invests the rudimentary brain, is not long persistent, but soon becomes partially converted into cartilage; the change commencing at the base in the Human fœtus at least as early as the second month, whilst the upper part retains its membranous condition until a much later period. The primordial cranial axis of Man, therefore, consists of three parts—1. A membranous roof; 2. Chiefly membranous lateral walls; and 3. A cartilaginous base.

The third, or osseous stage of development, is attained by four different processes, namely—1. By direct ossification of a portion of the cartilage of the pri-

* The various parts of the Skull, and their relations, may be understood by reference to the accompanying Diagram:—

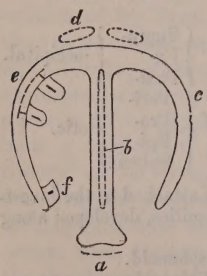
mordial cranium; 2. By part of the cartilage remaining unaltered; 3. By the disappearance of a small part of the primordial cartilage; and 4. By the deposition of new bone in the form of opercular, or splint bones, on the exterior of the primordial cranium. The first point of ossification appears immediately in front of the foramen magnum about the ninth week, and is the rudiment of the basilar portion of the occipital bone; a second (sometimes double) point forms in the third month at the fore part of the Sella turcica, and is the rudiment of the basi-sphenoid, or posterior portion of the sphenoid bone. Still more anteriorly, but a little later in point of time, a third double centre of ossification may be seen, which is the commencement of the pre-sphenoid, and in front of this again an ossification commences about the middle of fœtal life, which subsequently becoming greatly extended in a vertical direction, forms the perpendicular plate of the ethmoid. With each of these centres of ossification, situated along the floor or base of the skull, a superior arch is connected, composed of bones analogous to the laminæ and spines of the vertebræ, and, like them, enclosing and protecting the nervous mass within. The formation of the superior arch in connection with the basi-occipital centre commences at an early period, by the appearance of two additional ossifying points in the cartilage on either side of the foramen magnum, which develop into the condyloid and lateral portions of the occipital bone or ex-occipitals; whilst the crown of the arch, or supra-occipital bone, represented in the adult by the broad expanded plate, is formed by two osseous points in cartilage, and one or two in the membrane immediately above the cartilage that subsequently coalesce. The upper arch of the basi-sphenoid begins as a bony deposit in the cartilage representing the great wings of the sphenoid bone, or ali-sphenoids (*i*, Fig. 361); and the crown of this arch, formed by the parietals, is exclusively produced, not by intra-cartilaginous, but by intra-membranous ossification. A third upper arch is connected with the pre-sphenoid by the ossification of the projections of the pre-sphenoid (*k*), representing the alæ minores of the sphenoid or orbito-sphenoids, the crown of this arch also, the frontal bone, developing by intra-membranous ossification, like the parietal and upper part of supra-occipital bones. The most anterior of the centres of ossification that appears in the basal cartilage of the skull, forms the lamina perpendicularis of the ethmoid (*b*, Fig. 362), and is seen in vertical section in Fig. 362. At an early period the cartilage sends out two processes, *c*, *e*, which enclose the nasal fossæ. The superior and middle turbinals (opposite *e*) are developed as outgrowths from this cartilage. The inferior turbinal (*f*) is of later date. The nasal bones, *d*, *d*, are developed as opercular bones in the membrane covering the primitive cartilage, and overlie the nasal cartilage; whilst at the base of the cartilage, but developed in membrane, is the vomer (*a*). The remaining bone which enters into the formation of the skull is the Temporal, the development of which, formerly much misunderstood, has been very carefully investigated by Prof. Huxley, Mr. Parker, and others; from whose inquiries it appears that the squamosal portion, like the parietal and frontal bones, is developed from membrane. Below this, and developed from fibrous tissue, a ring of bone appears incomplete above, forming the auditory meatus, and termed the tympanic bone. Finally, there are three centres of ossification, for which Mr. Huxley proposes the terms, *prootic*, *epiotic* and *opisthotic*. The prootic lies behind the foramen

Fig. 362.



Vertical transverse section of anterior portion of the *Primordial basis cranii*: —*a*, position of vomer; *b*, perpendicular lamina of ethmoid; *c*, right ala of the cartilage, from which the turbinal bones, *e* and *f*, are seen projecting on the opposite side; *d*, nasal bones.

ovale, and forms the petrosal bone or petrous portion of the temporal. The epiotic surmounts the posterior vertical semicircular canal, and forms part of the mastoid portion of the temporal; whilst the opisthotic is continuous with the ossification which primitively surrounds the fenestra rotunda, and forms the floor of the Tympanum, lying in front of the point of exit of the 8th pair of nerves. The primary of the three principal sense organs, the nose, eye, and ear, are formed in connection respectively with the cerebral hemispheres, the thalamencephalon and the third primary vesicle. They are interpolated between the rudimentary parts of the head as follows:—1. The nose between the frontal, inter-maxillary and ethmoid; the eye between the frontal, sphenoid, ethmoid and maxillary; and the ear between the basi-occipital, ex-occipital, and ali-sphenoid.*

Fig. 363.

Human Embryo at the end of the third week:—1, 2, 3, 4, the visceral arches; *a*, the maxillary process; *b*, the eye.

753. The development of the *Face* next claims our attention. It proceeds from three parts, two of which are symmetrical and the third single. The former are the first pair of visceral arches (*a*, Fig. 363), sometimes termed the mandibular arch, from which the superior maxillary process is budded off on each side. The asymmetrical part is the frontal process, with its alæ or internal nasal processes (seen on each side of *nf*, Fig. 364), the development of which into the turbinals, covered by the nasals, has been already alluded to. The two lateral halves of the *first visceral arch* (1, Fig. 363) uniting in the middle line, form the rudiment of the lower jaw, and originally consist of two parts on each side, one of which, the inferior maxillary process, is cartilaginous, and becomes converted at its base into the malleus (*b*, Fig. 365), whilst its distal portion is prolonged downwards and forwards in the form of a slender rod, known under the name of Meckel's Cartilage, on the outer side of which the lower jaw (Fig. 365, *d*) is developed as a splint bone. The lower jaw thus stands in the same relation to Meckel's Cartilage that the opercular bones do to the primitive cranial bones; and it originally consists of two halves, united by a kind of synchondrosis, which does not ossify till after birth.—The malleus, which is the homologue of the quadrate bone of Birds, ossifies in the fourth month from the surface inwards, whilst Meckel's cartilage dies away, except near its root, which ossifies into the processus gracilis, or long process of the malleus. The superior maxillary process (*a*, Fig. 364) of the first visceral arch furnishes near its base the Pterygoid (*k*, Fig. 365) and distally the Palatine (*i*) bones, which begin to ossify in nascent or simple cartilage at about the close of the second month. The superior maxillary and zygomatic bones each ossify from one centre, at the end of the second month; and these, together with the lachrymals, are to be regarded as opercular bones. With regard to the inter-maxillary bone, it is probable that this is developed from two ossific centres in the membrane, independently of the superior maxilla, though they join with it about the middle of the third month.† Kollmann,‡ however, describes it as originating from the frontal process by two halves, which subsequently unite. The Vomer bears the same relation to

‡ "Zeits. f. Biolog.," Band iv. 1868, p. 274.

the base of the septum nasale, it appears in the third month, and has then the form of a semi-canal. At first, the mouth is a wide cavity, which is subsequently divided into a respiratory and digestive cavity by the lateral growth of the superior maxillary processes of the first visceral arch; thus constituting partitions on either side, called Palate plates, which after the eighth week begin to coalesce from before backward. An arrest of development at this period produces the deformity termed Cleft-palate. The *second visceral or hyoid* arch is originally in connection with the base of the skull, near the posterior sphenoid bone, but subsequently becomes segmented off, its apex or proximal portion remaining as the incus and os orbiculare in Man (which represent the hyo-mandibular of Fish), whilst its distal portion is converted into the styloid process of the temporal bone and cornu minus of the hyoid with the intervening membranous part (Fig. 365, *g*, *m*, *i*). The stapes proceeds from a cartilage developed in the fenestra ovalis, and is probably a periotic element. In the third visceral arch, which corresponds with the first branchial arch of Ichthyopsida, the cornu majus of the hyoid bone is developed on each side, ossifying in the eighth month. The basal plate is a common basi-hyobranchial.

754. From the foregoing brief outline of the development of the skull, it will be seen that no segmentation of the *cartilaginous* basis takes place at all analogous to that which occurs in the vertebral column at the same period of its development; and therefore, as Mr. Huxley observes, it is impossible to admit the existence of a series of cranial vertebræ, and still less to define their several parts by means of terms especially adapted to the description of those bones which constitute the spinal column. At the same time, a very superficial investigation of the process of ossification leads to the conclusion that this takes place in such a manner as to produce a series of segments which are the more closely analogous to those of the vertebral column the more posteriorly they are situated, as we see in the occipital and sphenoid segments; whilst in those that are more anterior, the modification of structure is so great, that scarcely any trace of the form of a vertebra remains, as appears in the case of the pre-sphenoid and ethmoidal segments.

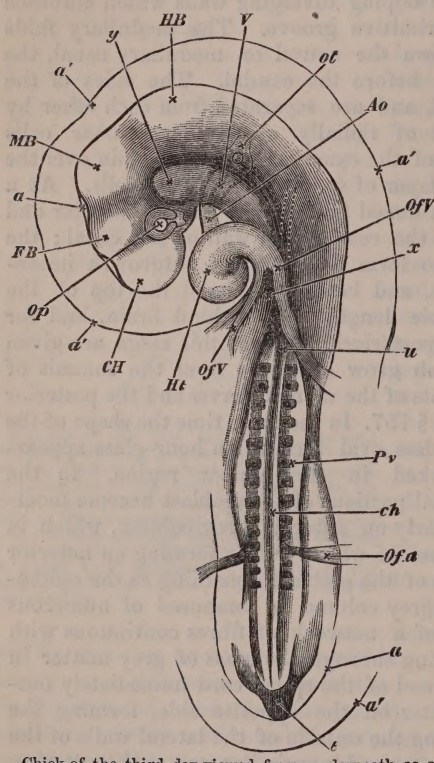
755. Within the Cranio-spinal canal thus formed, the rudiment of the Cerebro-spinal axis is found, at first under a very different aspect from that which it subsequently presents, especially as regards the relative proportion of its different segments. According to the investigations of Bidder, Kupffer, and Kölliker, in Man and Birds, the spinal cord consists, after the closure of the laminæ dorsales, of a canal surrounded by cells arranged in a radiating manner. These separate into an external layer composed of grey matter, and into an inner layer constituting the epithelium of the canal. The white substance appears later than the grey, and is unquestionably developed from it. In the first instance it consists of four cords or strands arranged in pairs,

which subsequently become connected in front by a white commissure.* According to the researches of Lockhart Clarke and Foster and Balfour, in Man, Mammalia, and Birds,† the spinal cord, in its earlier stages of development, consists of the medullary groove, which becomes narrower and deeper as it passes forwards until it reaches the head-fold, where it terminates by the medullary folds curving to meet each other and form a rounded end. Posteriorly, the medullary groove has sloping diverging walls which embrace between them the remains of the primitive groove. The medullary folds coalesce along the middle line to form the neural or medullary canal, the cervical portion of which is formed before the caudal. The sides of the neural canal are at first nearly parallel, and are separated from each other by a considerable interval, they consist of radially arranged columnar cells derived from the epiblast. The wall of the canal is exceedingly thin over the summit, where it consists of a single layer of somewhat flattened cells. At a later period the cells along the median dorsal line become slightly smaller and more spherical than those making up the rest of the wall of the canal; the spherical cells then grow upwards to form a prominent outgrowth immediately beneath the external epiblast, and between it and the top of the brain, which extends along the whole length of the hind brain, and for some distance anteriorly as well as posteriorly. From this ridge are given off at intervals paired processes which grow outwards from the summit of the cord to form the earliest rudiments of the cranial nerves and the posterior roots and ganglia of the spinal nerves.‡ § 757. In the mean time the shape of the neural canal changes from a more or less oval form to an hour-glass appearance which is more especially marked in the lumbar region. In the anterior region of the cord the external portions of the epiblast become modified into grey matter, forming anteriorly an anterior grey column, which in time is covered superficially by a mass of white matter forming an anterior white column. The internal portions of the epiblast remaining as the epithelium lining the spinal canal. The grey column is composed of numerous small nuclei which lie in the meshes of a network of fibres continuous with the fibres of the nerve root, and passing through the mass of grey matter in two directions (1) round the anterior end of the spinal cord immediately outside its epithelium, to the grey matter on the opposite side, forming the anterior commissure (2) upwards along the outside of the lateral walls of the canal. The posterior grey columns are formed in a similar way to the anterior. The walls of the constricted portion of the hour-glass shaped canal soon come into absolute contact, so that for a time two elliptical cavities are present. The roof of the posterior of these cavities is subsequently absorbed, thus transforming the canal into a wedge-shaped fissure—the posterior fissure. The anterior fissure is formed by the growth downwards of the anterior columns of the cord, which enclose between them a linear space. At a later period the posterior grey commissure and the anterior white commissure appear. As development progresses, a diversity of structure ensues in the grey substance; the cells or nuclei of the anterior grey substance becoming much larger than those of the posterior, and being connected by a coarser and more granular network. From these nuclei are developed a number of large roundish or irregular cells, with thick nucleated walls which are connected with the surrounding network, and have precisely the same appearance as the connective tissue of parts external to the cord. It appears, then, that in these early stages of development, there are at least two kinds of free

* Kölliker, "Entwick.," pp. 259, 260. † "Phil. Trans.," 1862, p. 911 *et seq.*
‡ Milnes Marshall, Humphry and Turner's "Journal," vol. xi. 1877, pp. 495, 496.

nuclei in the grey substance of the cord. One of these kinds appear to develop the general network of tissue which pervades the entire structure, but proceeds no farther; whereas each nucleus of the other kind, while connected with this network as well as with nerve-fibres, develops a nucleated cell, with a nucleated wall which is still connected, and ultimately blended, with the surrounding reticular structure. Through the medium of this intervening reticular structure, the walls of the nerve-cells, the walls of the blood-vessels, the processes of the epithelium, and the pia mater on the surface of the cord, are all uninterruptedly continuous with each other; and since the processes of nerve-cells constitute the axis-cylinders of the vaso-motor nerves distributed to parts external to the cord, Lockhart Clarke thought it probable that some of those processes which are lost by subdivision in the intervening nucleated and reticular tissue *within* the cord, were the means of transmitting nerve-power to that tissue, and through it, to the coats of its blood-vessels, from which, by their direct connection with them, the nerve-cells, in return, receive their supply of nutriment.

Fig. 366.



Chick of the third day viewed from underneath as a transparent object. *a'*, The outer amniotic fold or false amnion; *a*, the true amnion; *t*, tail; *CH*, cerebral hemisphere; *FB*, fore-brain or vesicle of the third ventricle; *MB*, mid-brain; *HB*, hind-brain; *op*, optic vesicle; *ot*, otic vesicle; *OfV*, omphalo-mesaraic veins forming the venous roots of the heart; *Ht*, heart, now completely twisted on itself; *Ao*, bulbus arteriosus, the thin aortic arches dimly seen uniting into the aorta, which is still more dimly seen as a curved dark line running along the body; the other curved dark line by its side ending near the reference *y* is the notochord, *ch*; *Ofa*, omphalo-mesaraic arteries; *Pv*, protovertebræ; *x*, is placed at the point of divergence of the splanchnopleure folds. The blind foregut begins here, and extends about up to *y*.

756. In the Bird, the medullary folds become closed in front, during the early part of the second day the posterior part remaining open for a short time, as the 'sinus rhomboidalis' which never completely closes in this class. The anterior extremity is dilated into a bulb, and forms the first cerebral vesicle. Two projections are formed at the sides which gradually become stalked, and constitute the optic vesicles. At the close of the second day the medullary canal presents two more dilatations separated from each other, and from the first cerebral vesicle by constrictions, so that instead of a single cerebral vesicle there are now, in addition to the optic vesicles, a series of them one behind the other. The most anterior of these, or the first cerebral vesicle, is developed into the fore-brain, the second into the mid-brain, and the third into the hind-brain. Before the end of the second day the first cerebral vesicle has begun to bud-off two small vesicles in front; these are the vesicles of the cerebral hemispheres, which subsequently become the most conspicuous part of the brain. As these are formed, owing to the more rapid growth of the upper surface of the body, the fore-brain, with the cerebral and optic vesicles, becomes slightly bent downwards over the anterior extremity

of the notochord, and this is the commencement of the cranial flexure. The cavity in the interior of each of the two vesicles of the cerebral hemispheres originating in the manner just described, constitutes the lateral ventricle, whilst the cavity of the fore-brain from which they were budded-off, remains as the cavity of the third ventricle, or, as Foster and Balfour term it, the "'tween-brain." On the summit of the 'tween-brain the rudiment of the pineal gland makes its appearance, whilst the floor is produced into the 'infundibulum,' which joins a process of the alimentary canal to form the pituitary body. The roof of the *mid-brain* becomes developed into the corpora bigemina or optic lobes in Birds, but into the corpora quadrigemina in Mammals; its floor is formed by the crura cerebri, and its cavity becomes reduced to the iter a tertio ad quartum ventriculum. In the *mid-brain* or third cerebral vesicle a constriction appears in the course of the third day, which indicates a division into the *cerebellum* in front, and the medulla oblongata behind. The fundamental parts of the brain are thus fairly mapped out in Birds on the third day. In Mammals the series of vesicles above described are distinctly visible at about the sixth week, and in the small proportion which the Cerebral Hemispheres bear to the other parts, in the absence of convolutions, in the deficiency of commissures, and in the general simplicity of structure of the whole, there is a certain correspondence between the brain of the Human embryo at this period and that of a Fish; but the resemblance is much stronger between the *fœtal* brain of the Fish and that of the Mammal; indeed, at this early period of their formation, the two could scarcely be distinguished; and it is the large amount of change which the latter undergoes, as compared with the former, that causes the wide dissimilarity of their adult forms. At about the twelfth week, we find the Cerebral Hemispheres much increased in size, and arching back over the Thalami and Corpora Quadrigemina (Fig. 367); still, however, they are destitute of convolutions, and are imperfectly connected by commissures; and there is a large cavity yet existing in the Corpora Quadrigemina, which freely communicates with the Third Ventricle. In all these particulars, there is a strong analogy between the condition of the brain of the Human embryo at this period and that of the Bird.—Up to the end of the third month, the Cerebral Hemispheres present only the rudiments of *anterior* lobes, and do not pass beyond that grade of development which is permanently characteristic of the Marsupial Mammalia, the Thalami being still but incompletely covered in by them. During the fourth and part of the fifth months, however, the middle lobes are developed from their posterior aspect, and cover the Corpora Quadrigemina; and the posterior lobes, of which there was no previous rudiment, subsequently begin to sprout from the back to the middle lobes, remaining separated from them, however, by a distinct furrow, even in the brain of the mature fœtus, and sometimes in that of older persons. In these and other particulars there is a very close correspondence between the progressive stages of development of the Human Cerebrum, and those which we encounter in the ascending series of Mammalia.*

757. The development of the *cranial and spinal nerves* has been recently

* See an account of the observations of Prof. Retzius on the Development of the Cerebrum, in the "Archives d'Anatomie Générale et de Physiologie," 1846.

studied by Prof. Milnes Marshall,* who finds that the earliest indications of nerves in the chick occurs about the twenty-second hour in the form of a longitudinal ridge of spherical cells to which the term "*neural ridge*" has been applied (§ 755). Previous to the coalescence of the medullary folds this ridge is situated on either side of the angle of reflexion of the epiblast: at a later period it coalesces with its fellow of the opposite side, and then lies upon the top of the neural canal, forming the "*neural crest.*" It first appears opposite the widest part of the mid-brain, and gradually extends backwards and forwards. The first commencement of the individual nerves are seen as lateral outgrowths of the neural crest, which thus appears to become specially prominent at certain points. In regard to the cranial nerves, Prof. Milnes Marshall finds that the olfactory (§ 760) and third nerves are both derived from the neural crest, and he therefore believes that they are morphologically equivalent to the hinder cranial or to the spinal nerves. The auditory nerve is developed as a branch of the seventh, which in turn is derived from the neural crest. The combined seventh pair is at first continuous with its fellow across the top of the neural canal, being connected with the hind-brain at its extreme summit. This attachment is preserved, however, for only a short period, as in the later stages the nerves become connected with the sides of the brain. The sixth nerve resembles the anterior roots of the spinal nerves in arising from the sides of the neural canal, and not from the neural crest, as well as in its comparatively late appearance. The glosso-pharyngeal and vagus nerves arise as a single outgrowth on either side from the neural crest in the posterior part of the hind-brain, and behind the auditory involution. The origin of the ophthalmic fourth and fifth nerves, has not yet been accurately determined. Certain of the cranial nerves, *e.g.*, the third, the facial, and glosso-pharyngeal possess a segmental value. The mode of development of these segmental cranial nerves agree among themselves and differ sharply from other nerves or branches of nerves in the following embryological characters :—(1.) They appear very early. (2.) They appear, at least in the chick, from the neural crest on the mid-dorsal surface of the brain. (3.) Shortly after their appearance their roots undergo a shifting downward of their points of attachment, so that they no longer arise from the dorsal surface, but from the sides of the brain. (4.) They present, at least in their early stages, ganglionic enlargements on or close to their roots of origin. (5.) Their course is at right angles to the longitudinal axis of the head. (6.) Finally they have very definite relations to the segments of the head as indicated by the visceral clefts, each nerve supplying the two sides of a cleft. Of these visceral clefts, Prof. Marshall considers the olfactory as the most anterior, the olfactory being the segmental nerve in connection with it. The lachrymal or cleft in front of the maxillary arch is the second, the third nerve which divides beyond its distal ganglionic swelling being in connection with its two sides. The buccal or mouth cleft is the third visceral, it lies between the maxillary and mandibular arches, and is in connection with the fifth nerve. Behind this is the hyo-mandibular or spiracular cleft supplied by the facial nerve and constituting the fourth visceral cleft; and then the branchial clefts which are early closed, but remain in Branchiate vertebrates. The branchial clefts are seven in number, and are supplied by the glosso-pharyngeal and by the several branches of the vagus. Mr. Parker, however, does not agree with the views here adopted, chiefly on the grounds that the nasal lachrymal and oral clefts contain no hypoblast, while they are involutions and not clefts in the strict sense of the word.

The relations of the segmental nerves as determined by Mr. Balfour (Table A.) and Prof. Marshall (Table B) are well shown in the two following Tables:*—

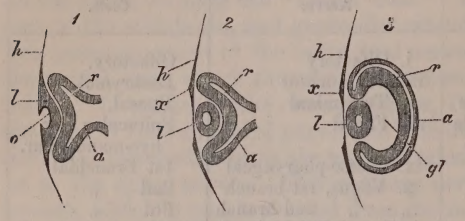
,, 8	8th ,, ,,	4th ,, ,,	5th ,, ,,

The posterior roots and ganglia of the spinal nerves are like the cerebral nerves derived from lateral outgrowths of the neural crest, a pair of processes being given off opposite the posterior part of each proto-vertebra. The processes at first grow outwards beneath the external epiblast, but subsequently, owing to changes in the shape of the embryo, they pass downwards between the muscle-plates and the spinal cord. The proximal extremity of each process becomes more slender, and its point of attachment shifts outwards: whilst the distal portion enlarges considerably and becomes a spinal ganglion. Finally, as development proceeds, the spherical cells which form the processes become elongated and fibrillar, and somewhat resemble the cells of the mesoblast which surround them. The anterior roots of the spinal nerves appear later than the posterior roots, arising as slender outgrowths from the lower part of the sides of the spinal cord: they are composed of elongated fusiform cells, except at their points of attachment to the cord, where the cells are small and spherical The anterior roots subsequently grow out to meet the posterior, and so form the spinal nerves which run downwards on the inner side of the muscle-plate.

* Prof. Marshall, 'Morphology of the Vertebrate Olfactory Organ,' "Quart. Journ. Micros. Sci.," vol. xix. (1879), p. 334; Mr. Balfour 'Development of Elasmobranch Fishes, "Humphry and Turner's Journal," vol. xi. 1877, p. 482; "Monograph," p. 216.

758. The development of the *Eye** commences by a protrusion from the lower and posterior part of the anterior cerebral vesicle (§ 756), the cavity of the protrusion being continuous with that of the vesicle itself; very soon, however, it loses all connection with the Cerebral Hemispheres, and opens exclusively into the 'third ventricle.' As soon as the primitive optic vesicle has assumed its permanent position, the Epiblast over it becomes thickened (Fig. 368, 1), whilst the subjacent wall of the optic vesicle becomes indented, and at length so far pushed in as to form a sac composed of two layers, the edges of which surround the lens (Fig. 368, 2). This sac is the 'secondary optic vesicle' or 'cup.' The anterior thicker layer (Fig. 368, 3 *r*) is developed into the retina, the posterior (*a*) becomes the hexagonal tessellated pigment layer. The doubling-in of the primary optic vesicle is so conducted that a slit remains for a short time, termed the choroidal fissure, through which a portion of mesoblast gains entrance into the interior of the vesicle. The thickened layer of the epiblast (*e*) becoming detached constitutes the lens, a thin layer of the epiblast still remaining, which forms the epithelium of the cornea. The mesoblast surrounding the optic vesicle gradually forms a distinct investment for it, of which the outer part constitutes the sclerotic and cornea, and the inner the proper tissues and vessels of the choroid, whilst another portion penetrating more deeply constitutes the suspensory ligament and capsule of the lens, and the vitreous. The choroid only reaches as far as the edge of the lens at first, and no trace of Iris can at that time be discovered. At the end of the second month the iris, at first represented by a colourless lamina in which pigment is afterwards deposited, grows out from the edge of the choroid, and insinuates itself between the lens and the cornea. The development of the anterior half of the Retina ceases during the latter part of fœtal life, and this part is gradually transformed into the Pars ciliaris, which in the adult does not contain any nervous element. The Macula lutea is not present in the embryo, nor in the new-born infant. The optic nerve, which is at first hollow, gradually becomes solid by the growth of fibres which fill its cavity. The *Chiasma* appears at an early period, and results from the fibres of the one stalk growing over into the attachment of the other. This takes place soon after the deposition of pigment in the outer wall of the optic cup, and about the same time the fibres at the neck of the optic cup grow forward and become connected with the retina, over whose internal surface they spread.†

Fig. 368.



Longitudinal section of the *Eye of Embryo Fowl*:—1, from an embryo at about the 65th hour of incubation; 2, from an embryo a few hours older; 3, from an embryo at the 4th day of incubation:—*h*, epiblast; *l*, lens in Fig. 1, still connected with the epiblast, and possessing a small cavity (*o*) in its interior,—in Figs. 2 and 3 it is seen detached but still hollow; *r*, introverted portion of the primitive optic vesicle, subsequently becoming the retina; *a*, posterior part of the optic vesicle, which, according to Remak, probably becomes the choroid coat, ciliary processes, and iris, and in Figs. 1 and 2 is still connected with the brain by the hollow optic nerve; *x*, thickening of the epiblast around the spot from which the lens has detached itself; *gl*, vitreous body.

759. *Development of the Ear.*—The Ear makes its first appearance in the Fowl on the second day, as an involution of the Epiblast over the hind-brain;

* See the excellent Memoir of the late Mr. H. Gray in the "Philosophical Transactions," 1850; Kölliker, "Entwickel. des Menschen," 1879, pp. 623–703, et auct. ib. cit.; Peter Young, 'On the Development of the Eye in the Chick,' "Med.-Chir. Rev.," 1858, vol. xxii. p. 187; and Klebs in Virchow's "Archiv," Band xxviii.

† Foster and Balfour, "Elements of Embryology," 1874, pp. 94–111.

and the pit thus formed becomes converted into a sac by the narrowing and closure of its mouth. This sac is the 'otic vesicle,' and is lined by epiblast and surrounded by mesoblast. By the outgrowth of the vesicle in different directions, the semi-circular canals and cochlea are developed, the mesoblast forming both their membranous and osseous walls, whilst the epiblast remains as their epithelial investment, and consequently forms the proper auditory apparatus of hair cells, &c. The auditory nerve rises, as has been already stated (§ 757), in common with the facial; that portion of the combined root which becomes the auditory nerve is considerably larger than that from which the facial is derived. It passes downwards and backwards as a large ganglionic mass closely applied to the anterior wall of the auditory vesicle, with the epithelium of which it comes into contact at a very early period, and subsequently completely fuses with it. In Man the vesicles are first found about the 4th week, possessing an epithelial lining derived from the epiblast; these are the Vestibula. The vesicles or vestibules then close and become pyriform; and the small end pushes out a hollow, club-shaped process, 'processus vestibuli,' which is connected with the dura mater, its peduncle passing through the Aquæductus vestibuli to the Atrium. Dr. Urban Pritchard* finds that *the organ of Corti* is developed from a certain number of the epithelial cells lining the rudimentary ductus cochlea, which itself starts as a bud from the vestibular labyrinth. The bud elongates and assumes a spiral form, so that at an early period of development the cochlea is represented by a spiral tube lined with epithelium, and surrounded by stellate embryonic tissue. During the further development of the organ of Corti, the rods, membrana reticularis and vertical trabeculæ are formed from the walls of the original epithelial cells, whilst the ciliated and other cells are formed from their contents. The membrana tectoria is a secretion from the same original epithelium. The Semicircular Canals are at first straight tubes, receiving their characteristic curvature and ampullæ at a later period. The remaining portion of the vestibule forms the Fovea hemispherica and the Fovea hemi-elliptica. The petrous portion of the temporal bone is developed from the mesoblast surrounding the labyrinth, which subsequently becomes cartilaginous (8th week). In Man the cochlea makes one entire turn in the 8th week; at the end of the 3rd month the canal is complete. The spiral lamina is not completed till after the 6th month.—The modiolus and the spiral lamina only ossify in the last months. The Middle Ear (including the external meatus, tympanum, and Eustachian tube) is formed by the partial closure of the first branchial cleft at the 4th week. At the 3rd month the ossicula are formed, and are then seen lying *over*, not in, the tympanic cavity, imbedded in gelatinous tissue. The Eustachian tube remains closed during the whole of fœtal life by gelatinous tissue, the cartilaginous portion being formed at the 4th month. The mastoid cells only appear at puberty. The membrana tympani is at first very thick, and horizontal in position.—The *External Ear* is developed from the Annulus tympanicus, § 752, a small bone which can be separated at birth, and gradually elongates. The cartilage and auricle are formed from the skin that surrounds the outer opening of the first branchial cleft. The auditory capsule is developed, according to Huxley, from three separate ossifications arising in the periotic cartilaginous mass;—an anterior ossification, the prootic, a superior and posterior one, the epiotic, and an inferior and posterior one, the opisthotic. These ossifications unite with each other, with the squamosal and with the tympanic bone to form the temporal. Of the three

* Humphry and Turner's "Journ. of Anatomy and Physiology," vol. xiii. 1879, p. 99; "Proc. Roy. Soc.," vol. xxiv.

ossicula auditûs,* according to Prof. Parker,† the stapes is a cartilage developed in the fenestra ovalis, it is a periotic element and cannot be proved to be hyoid. It is the equivalent of the base of the columella of air-breathing ovipara. The incus is part of the hyoid arch and not of the mandibular. The mandibular is divisible into antero-superior and postero-inferior portions; the antero-superior being the pterygo-palatine. The postero-inferior part of the hyoid in Man is the styloid and cornu minus with the intervening membranous portion, the cornu majus being a rudiment of the first branchial arch of an osseous Fish. The malleus is the proximal portion of the first visceral arch, and is the modified os quadratum of fish, reptiles, &c. The processus gracilis, at an early period of fœtal life, is the cartilage of Meckel, and meets its fellow in the middle line below the mouth, forming a perfect primordial lower jaw.

760. *Organ of Smell.*—According to von Baer, the nasal fossæ are at first distinct from the oral cavity, subsequently communicate with it, and are finally divided into two portions, of which one becomes the respiratory portion of the nasal cavity, whilst the other forms the true olfactory portion and labyrinth of the Nose. In the development of the Olfactory nerve and organ,‡ the nerves arise as solid rods from the upper part or neural crest of the fore-brain before any trace of the cerebral hemispheres. With the development of the hemispheres the olfactory nerves become pushed down towards the ventral surface of the brain, and acquire a secondary connection with the hemispheres. The olfactory lobe first appears as a depression on the inner side of the fore-brain some time after the nerves are visible. The olfactory organs make their first appearance as a pair of slight thickenings of the external epiblast on the under surface of the fore-brain immediately in front of the mouth. Each thickened patch of skin soon becomes involuted as a shallow pit. Prof. Marshall points out the close analogy of the pit to a visceral cleft, and of the folds that subsequently form in it to a gill, and he concludes that the olfactory organ is the most anterior visceral cleft; that the olfactory nerve is the segmental nerve supplying the two sides of the cleft in a manner precisely similar to that in which the hinder clefts are supplied by their respective nerves; and that the Schneiderian folds are homologues of the gills. In the Human subject two depressions, the nasal fossæ, are well marked at the end of the 4th week. In the 6th week these fossæ communicate below with the oral cavity by a groove. At the end of the 2nd month the groove closes, and the labyrinth communicates with the most anterior part of the oral cavity by means of two narrow orifices, which are themselves rapidly closed by the formation of the palate dividing the nose from the mouth, slight traces of them remaining in adult life in the Naso-palatine foramen. At the 10th week the posterior nasal orifices are formed on either side of the Septum. The Labyrinth is wholly developed from the epiblast investing the nasal fossæ. It is fully formed at the close of the 3rd month, though the accessory cavities of the frontal, sphenoidal, and ethmoidal sinuses, with the antrum of Highmore, are still absent, and are not completed till after the 6th month. The outer nose begins to grow out of the nasal part of the primordial cranium about the end of the 2nd month. In the 3rd month the nasal orifices are closed by a gelatinous plug, which disappears after the 5th

† Note to the Editor.

‡ Which has been carefully worked out by Dr. Milnes Marshall, "Quart. Journ. of Mic. Sci.," 1879, p. 300; and 1878, p. 17; and "Journ. of Anat. and Phys.," vol. xi.

month, and seems to consist of mucus and epithelial plates. The several steps of the development of this organ are met with in the various classes of animals: the small closed fossæ remind us of Fishes; the short nasal ducts opening into the anterior part of the mouth, of Batrachians, &c.

761. *The extremities* (Fig. 346, *qq*, *rr*) appear in Man about the fourth week, as small and undivided stumps from the lateral plate; those of the upper extremity appearing first: a division into two principal parts takes place in the fifth week; one of which is broad, and shows about the fifth week four indentations; the other is more cylindrical, and subdivides into a fore and upper arm about the eighth week. The two extremities are very similar in form up to this period, their distinctive characters only appearing well marked at the third month. All the bones which enter into their composition pass through stages of development similar to those that have been already described as occurring in the bones of the vertebral column and skull. In the first instance only a soft blastema or indifferent tissue appears in the place of the future bone: but this gradually develops into cartilage, the conversion being complete about the end of the second or the commencement of the third month, and in the cartilage again points of ossification make their appearance, with great though not absolute precision, for each bone, not only as regards number, but also as to time and position.* The fore and hind limbs also undergo certain changes in their position, which adapt them to their future functions.

762. *Of Sex.*—The conditions on which the differentiation of sex immediately depend are yet extremely obscure. M. Marc Thury,† who has paid great attention to this subject in cattle, has arrived at the conclusion (which, however, demands much confirmatory evidence for its establishment) that the sex of the progeny of a particular act of sexual intercourse is dependent upon the period of menstruation (in women) or of rut (in animals), at which the impregnation of the ovum takes place. If this occur at the commencement of the period, the offspring will invariably be a female; if towards the close, a male: the cause of the difference being the more advanced stage of maturation of the ovum in the latter case, owing to its having been for a longer period exposed to the warmth of the body of the mother. Ploss‡ attributes the sex of the child to the quantity and quality of the nutriment received by the mother during pregnancy, since from a review of various countries, and a comparison of the relative numbers of males and females born, he finds that when the food is abundant and plentiful, the proportion of females rises; whilst, under opposite conditions, males are most frequent. In mountainous countries the number of males also increases relatively. Preussen (loc. cit.), however, on the other hand, considers that better and more abundant food is required by the mother for the production of males; whilst other observers have supposed that the child will be of the sex of the parent who has the strongest constitution.§—There is strong statistical evidence that the relative numbers of Males and Females are in some way influenced by the relative *ages* of the parents. The following Table expresses the average results collected by M. Hofacker‖ in Germany, and by Mr. Sadler¶ in Britain; between which it will be seen that there is a very striking general correspondence, although both were drawn from a too limited series of observa-

From this it appears that the more advanced age of the Male parent has a very decided influence in occasioning a preponderance in the number of Male infants; and this tallies with the fact, that taking the average of the whole of Europe, over which (as a general rule) the state and customs of society bring about a decided preponderance of age, among married couples, on the side of the husband, the proportion is about 106 males to 100 females. This does not hold good, however, in regard to *illegitimate* offspring, the parents of which may generally be presumed to be more nearly on an equality in this respect; and it is curious that the proportion of these has averged 102·5 males to 100 females, in places where the proportion of *legitimate* births was 105¾ males to 100 females.—We are not likely to obtain data equally satisfactory in regard to the influence of more advanced age on the part of the Female parent; as a difference of 10 or 15 years on that side is not so common. If it exist to the same extent, it is probable that the same law would be found to prevail in regard to Female children born under such circumstances, as will be stated (§ 763) with respect to the Male—namely, that the mortality is greater during embryonic life and early infancy, so that the preponderance is reduced. Even at birth, there is a manifest difference in the physical conditions of infants of different sexes; for, in the average of a large number, there is a decided preponderance on the side of the Males, both as to the length and the weight of the body. And it seems not improbable that this difference has a decided influence upon the greater loss of life in the act of parturition which occurs among Male infants.

I. The *Length** of the body in fifty new-born infants of each sex showed an *average* difference of 4½ lines in favour of the Male.

II. The average Weight of infants of both sexes, as determined by Quetelet, is 3·05 kilog. or 6·77 lbs.; and this corresponds almost exactly with the statement of Chaussier, whose observations were made upon more than 20,000 infants. The mean obtained by him, without reference to distinction of sex, was 6·75 lbs.; the maximum being 11·3 lbs., and the minimum 3·2 lbs.† The average in this country is probably rather higher; according to Dr. Joseph Clarke,‡ whose inquiries were made on 60 males and 60 females, the average weight of Male children is 7⅓ lbs., and that of Females 6⅔ lbs. He adds that children which at full time weigh less than 5 lbs. rarely thrive; being generally feeble in their actions, and dying within a short time. Several instances are on record of infants whose weight at birth exceeded 15 lbs. It appears that healthy females, living in the country, and engaged in active but not over-fatiguing occupations, have generally the largest children; and this is what might be expected *à priori*, from the superior energy of their nutritive functions. A fœtus which has been full 40 weeks in utero, the

* For details of fifty cases, see Quetelet, "Sur l'Homme," tom. ii. pp. 8 and 35.

† These numbers have been erroneously stated in many Physiological works, owing to the difference between the French and English pound not having been allowed-for.

‡ "Philosophical Transactions," vol. lxxvi.

mother and father being healthy and well nourished, should measure 20 inches at birth; the *average* is 18 inches. It takes three years to grow the next 18 inches, which is four times as long as the nine months in utero, and it takes about eight years to grow the third 18 inches. After this, 2, $2\frac{1}{2}$, or 3 inches a year goes on up to the time of final retardation at puberty.*

	Ft.	In.		Ft.	In.		Ft.	In.
Birth . .	1	6	4 years . .	3	$2\frac{1}{2}$	8 years . . .	4	$0\frac{1}{2}$
1 year . .	2	4	5 „ . .	3	5	9 „ . . .	4	3
2 years . .	2	8	6 „ . .	3	$7\frac{1}{2}$	10 „ . . .	4	$5\frac{1}{2}$
3 „ . .	3	0	7 „ . .	3	10	11 „ . . .	4	8

This rate goes on up to puberty, so that at 14 the height should be 5 ft. $3\frac{1}{2}$ in. Females rarely grow much after this, but males continue to grow at the rate of 1 inch a year for 3 or 4 years, stopping at $5 \cdot 7\frac{1}{2}$. This is the rate of average English growth.

763. There appears to be, from the first, a difference in the *Viability* (or probability of life) of Male and Female children; for, out of the total number born dead, there are 3 Males to 2 Females; this proportion gradually lessens, however, during early infancy; being about 4 to 3 during the first two months, and about 4 to 5 during the next three months; after which time the deaths are nearly in proportion to the numbers of the two sexes respectively, until the age of puberty. The viability of the two sexes continues to increase during childhood; and attains its maximum between the 13th and 14th years. For a short time after this epoch has been passed, the rate of mortality is higher in Females than in Males; but from about the age of 18 to 28, the mortality is

FIG. 369.

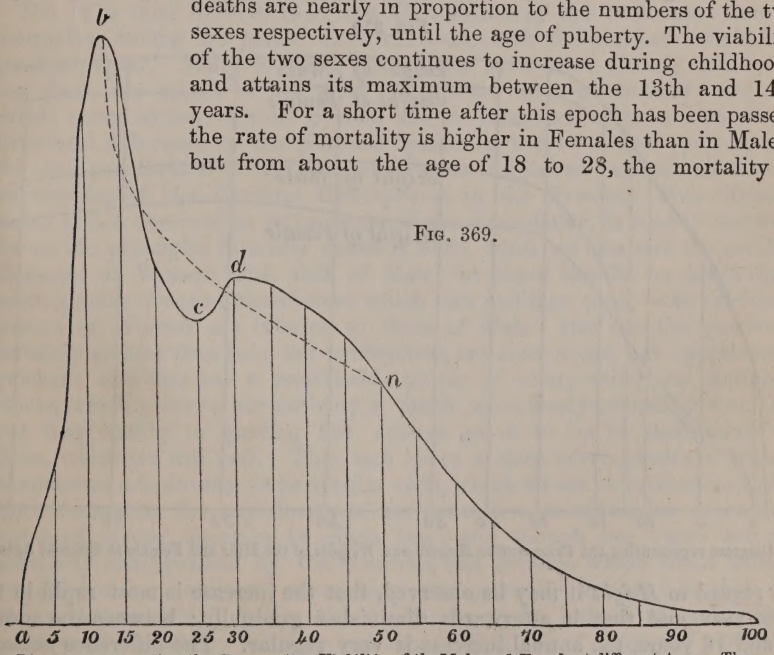

Diagram representing the *Comparative Viability of the Male and Female* at different Ages. The dotted line represents the viability of the female.

much greater in Males, being at its maximum at 25, when the viability is only half what it is at puberty. The fact is a very striking one; and shows most forcibly that the indulgence of the passions not only weakens the health, but in a great number of instances is the cause of a very premature death. From the age of 28 to that of 50, the mortality is greater and the

* 'On the Physical Development of Children,' by Percy Boulton, M.D., "The Lancet," 1880, vol. ii. p. 610.

viability less on the side of the Female; this is what would be anticipated from the increased risk to which she is liable during the parturient period. After the age of 50, the mortality is nearly the same for both.—These facts have been expressed by Quetelet* in a form which brings them prominently before the eye (Fig. 369). The relative viability of the Male at different ages is represented by a curved line; the elevation of which indicates its degree, at the respective periods marked along the base line. The dotted line, which follows a different curve, represents the viability of the Female. Starting from *a*, the period of birth, we arrive at the maximum of viability for both at *b*: from this point, the Female curve steadily descends towards *n*, at first very rapidly, but afterwards more gradually; whilst the male curve does not descend quite so soon, but afterwards falls much lower, its minimum being *c*, which corresponds with the age of 25 years. It afterwards ascends to *d*, which is the maximum of viability subsequently to the age of puberty; this point is attained at the age of 30 years, from which period, up to 50, the probability of life is greater in the Male than in the Female. In the decline of life, there seems little or no difference for the two sexes.

764. Similar diagrams have been constructed by Quetelet, to indicate the relative Heights and Weights of the two sexes at different ages (Fig 370).—

Fig. 370.

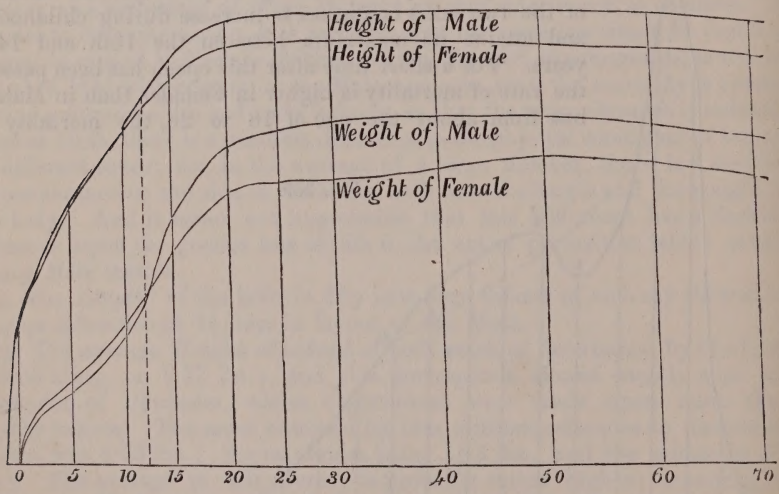

Diagram representing the *Comparative Heights and Weights* of the Male and Female at different Ages.

In regard to *Height* it may be observed, that the increase is most rapid in the first year, and that it afterwards diminishes gradually; between the ages of 5 and 16 years, the annual increase is very regular. The difference between the Height of the Male and Female, which has been already stated to present itself at birth, continues to increase during infancy and youth; it is not very decided, however, until about the 15th year, after which the growth of the Female proceeds at a much diminished rate, whilst that of the Male continues in nearly the same degree, until about the age of 19 years. It appears, then, that the Female comes to her full development in regard to Height, earlier than does the Male. It seems probable, from the observations of Quetelet, that the full Height of the Male is not generally attained until the age of

* Op. cit.

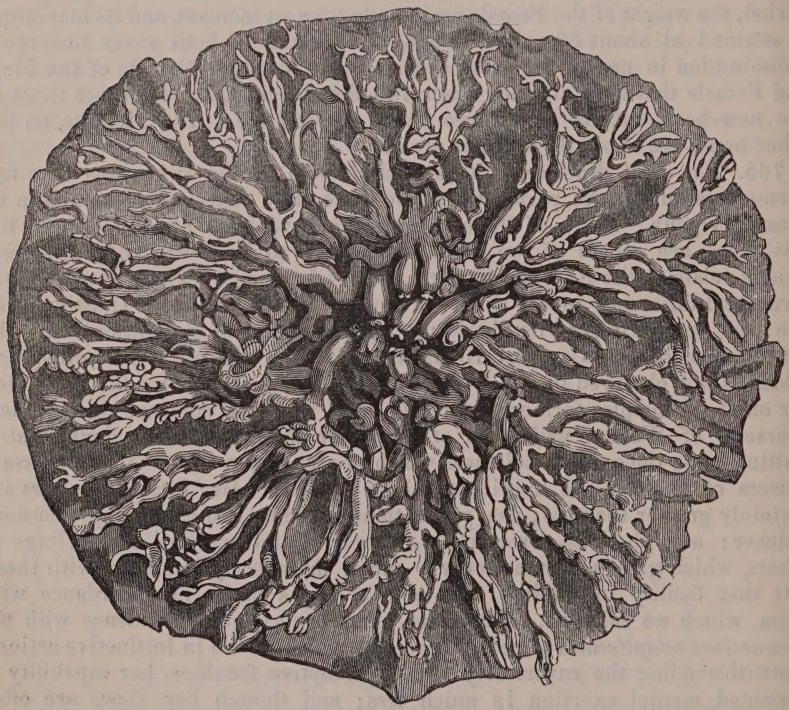
25 years. At the age of 50, both Male and Female undergo a diminution of their stature, which continues during the latter part of life.—The proportional *Weight* of the two sexes at different periods, corresponds pretty closely with their height. Starting from birth, the predominance then exhibited by the Male gradually increases during the first few years; but towards the period of puberty, the proportional weight of the Female increases; and at the age of 12 years there is no difference between the two sexes in this respect. The weight of the Male, however, then increases much more rapidly than that of the Female, especially between the ages of 15 and 20 years; after the latter period there is no considerable increase on the side of the Male, though his maximum is not attained until the age of 40; and there is an absolute diminution on the part of the Female, whose weight remains less during nearly the whole period of child-bearing. After the termination of the parturient period, the weight of the Female again undergoes an increase, and its maximum is attained at about 50. In old age, the weight of both sexes undergoes a diminution in nearly the same degree. The average Weights of the Male and Female that have attained their full development, are 20 times those of the new-born Infants of the two sexes respectively. The Heights, on the other hand, are about $3\frac{1}{4}$ times as great.*

765. The chief differences in the *Constitution* of the two sexes manifest themselves during the period when the Generative functions of each is in its greatest vigour. Many of these distinctions have been already alluded to; but there are others of too great importance to be overlooked; and these chiefly relate to the Nervous System and its functions. There is no obvious structural difference in the Nervous System of the two sexes (putting aside the local peculiarities of its distribution to the organs of generation), save the inferior size of the Cerebral Hemispheres in the Female. This difference, which is not observed in other parts of the Encephalon, is readily accounted for on the principles formerly stated (§ 506), when we compare the psychical character of Woman with that of Man; for there can be no doubt that—putting aside the exceptional cases which now and then occur—the *intellectual* powers of Woman are inferior to those of Man. Her *intuitive* powers are certainly greater than his; her perceptions are more acute, her apprehensions quicker; and she has a remarkable power of interpreting the feelings of others, which gives to her not only a much more ready sympathy with them, but that facility in guiding her actions so as to be in accordance with them, which we call *tact*. This tact bears a close correspondence with the *unconscious adaptiveness* to particular ends, which we see in Instinctive actions. Notwithstanding the superiority of her perceptive faculties, her capability of sustained mental exertion is much less; and though her views are often peculiarly distinguished by the clearness and decision which result from the strength of her intuitive sense, they are generally deficient in that comprehensiveness which brings the *whole* case to be judged of, and which is consequently necessary for their stability. With less of *volitional* power than Man possesses, she has the *emotional* in a much stronger degree. The emotions, therefore, predominate; and more frequently become the leading springs of action than they do in Man. By their direct influence upon the bodily frame they produce changes in the Organic functions, which far surpass in degree anything of the same kind that we ordinarily witness in Man; and they thus not unfrequently occasion symptoms of an anomalous kind, which are very perplexing to the Medical practitioner, though very interesting

* For an excellent Treatise on "The Stature and Bulk of Man in the British Isles," see John Beddoe, Pamphlet, 187 0, p. 191.

to the Physiological observer. But they also act as powerful motives to the Will; and, when strongly called forth, produce a degree of vigour and determination which is very surprising to those who have usually seen the individual under a different aspect. But this vigour, being due to the strong excitement of the Feelings, and not to any inherent strength of Intellect, is only sustained during the persistence of the motive, and fails as soon as this subsides. The feelings of Woman, being frequently called forth by the occurrences she witnesses around her, are naturally more disinterested than those of Man; *his* energy is more concentrated upon one object; and to this his Intellect is directed with an earnestness that too frequently either blunts his feelings, or carries them along in the same channel, thus rendering them

Fig. 371.



Distribution of the *Milk-ducts* in the Mamma of the Human Female, during lactation; the ducts injected with wax.

selfish.—In regard to the inferior development of her Intellectual powers, therefore, and to the predominance of the Instinctive, Woman must be considered as ranking below Man; but in the superior purity and elevation of her Feelings, she is as highly raised above him. Her whole character, Psychical as well as Corporeal, is beautifully adapted to supply what is deficient in Man; and to elevate and refine those powers which might otherwise be directed to low and selfish objects.

5. *Of Lactation.*

766. The new-born Infant in the Human species, as in the class of Mammalia generally, is supplied with nourishment by a secretion elaborated from the blood of its maternal parent, by certain glandular organs known as the

Mammary. The structure of these, which has been thoroughly investigated by Sir A. Cooper* and Mr. Birkett,† is extremely simple. Each gland is composed of a number of separate lobules which are connected together by connective tissue containing a few elastic fibres, in such a manner as to allow a certain degree of mobility of its parts, one upon another, which may accommodate them to the actions of the Pectoralis muscle whereon they are bound down; and the lobules are also connected by the ramifications of the lactiferous tubes, which intermingle with one another in such a manner as to destroy the simplicity and uniformity of their divisions, although they rarely inosculate. The galactophorous or terminal ducts contained in the nipple are usually about ten or twelve in number; they are straight, but of somewhat variable size; and their orifices, which are situated in the centre of the nipple, and are usually concealed by the overlapping of its sides, are narrower than the tubes themselves. At the base of the nipple, these tubes dilate into reservoirs, which extend beneath the areola and to some distance into the gland, when the breast is in a state of lactation. These are much larger in many of the lower Mammalia than in the Human female, in whom their use is to supply the immediate wants of the child when it is first applied to the breast, so that it shall not be disappointed, but shall be induced to proceed with sucking until the 'draught' be occasioned (§ 681). From each of these reservoirs commence five or six branches of the *lactiferous tubes*, each of which speedily subdivides into smaller ones; and these again divaricate, until their size is much reduced, and their extent greatly increased (Fig. 371). These, like the reservoirs and galactophorous tubes, are composed of a connective tissue sheath lined by short polyhedral or columnar epithelium cells, they differ, however, in possessing no unstriped muscular fibres; the epithelium forms a secretion of its own, which sometimes collects in considerable quantity when the milk ceases to be produced. The smaller subdivisions of the lactiferous tubes proceed to distinct lobules; so that when a branch of a galactophorous tube has been filled with injection, its attached lobules, if separated from each other by long maceration, are like a bunch of fruits clustered upon a stalk (Fig. 372). When the lactiferous tubes are pursued to their ultimate distribution, they are found to terminate in follicles, whose size, in full lactation, is that of a hole pricked in paper by the point of a very fine pin, so that, when distended with quicksilver or milk, they are just visible to the naked eye; at other times, however, the follicles do not admit of being injected, though the lactiferous tubes may have been completely filled. They consist of longer or shorter wavy and convoluted tubes possessed of cylindrical or saccular lateral branchlets. The diameter of the follicles is larger than that of the terminal ducts, each is limited by a membrana propria lined with an epithelium consisting of a single layer of granular-looking epithelium cells each with a spherical nucleus. In the centre of each follicle is a distinct lumen; in the follicles which are secreting milk the lumen is very conspicuous, and is bounded by polyhedral or cubical epithelial cells, some of

Fig. 372.

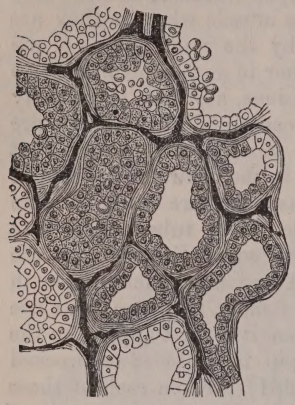
* "On the Anatomy of the Breast," 1840.

† "The Diseases of the Breast, and their Treatment," 1850. See also Giannuzzi, "Rivista Scientif. del. Akad. de Fisiocritici," ii. p. 38; Creighton, 'On the Development of the Mamma and of the Mammary Function,' Humphry and Turner's "Journal," vol. xi. 1877, p. 1; and Klein and Noble Smith's "Atlas of Histology," 1880, p. 300.

which contain larger or smaller milk globules (Fig. 373); whilst in those in which no secretion is taking place, the lumen is minute, and the epithelial cells are uniform and more or less columnar. The milk globules contained in the epithelium cells are each distinctly contained in a vacuole in the substance of the cell, but they possess their own delicate albuminous membrane. The arteries which supply the lobules with blood, become very large during lactation; and their divisions spread themselves minutely on the follicles. From the blood which they convey the milk is secreted by the epithelium and discharged into the follicles, whence it flows into the ducts. Absorbent vessels are seen to arise in large numbers in the neighbourhood of the follicles; their function appears to be to absorb the more watery part of the milk contained in the follicles and tubes, so as to render it more nutrient than it is when first secreted; and also to relieve the distension which would occur, during the absence of the child, from the continuance of the secreting process.

Fig. 373.



Section of Mammary gland.

767. The Mammary gland may be detected at an early period of fœtal existence; being easily distinguishable from the surrounding parts by the redness of its colour and its high vascularity, especially when the whole is injected. According to Dr. Creighton's observations (loc. cit.) it is first seen as a whitish strip of tissue running through a large body of fat. From the long central tract, short and inconspicuous offshoots project into the surrounding fat. The lobules develop at many separate points in this the matrix tissue, the embryonic cells from which they develop being of the same kind as those which give rise to the surrounding fat tissue. The ducts of the mamma develop from the same matrix tissue by direct aggregation of the embryonic cells along predetermined lines. In the guinea-pig, upon which these observations were conducted, the ducts develop before the lobules. The homologue of the mamma is not, therefore, a cutaneous gland of the type which is developed as an invagination of the ectoderm, but it is a fat body. At first the gland presents no difference in the male and female; and it is not until near the period of puberty that any striking change manifests itself, the gland continuing to grow, in the one sex as in the other, in proportion to the body at large. At about the age of thirteen years, however, the enlargement of the gland commences in the Female: and by sixteen, it is greatly evolved, and some of the lactiferous tubes can be injected. At about the age of twenty, the gland attains its full size previous to lactation; but the milk-follicles cannot even then be injected from the tubes. During pregnancy, the mammæ receive a greatly increased quantity of blood. This determination often commences very early, and produces a feeling of tenderness and distension, which is a valuable sign (where it exists in connection with others) of the commencement of gestation (§ 717). A true lacteal secretion* usually

* De Sinéty ("Journ. de Physiol.," July, 1875) confirms the well-known fact that the mammæ of new born infants of both sexes, especially at the third and fourth day after birth, secrete milk. The Author finds that the milk thus obtained is the result of a true secretion, and that the anatomical and physiological state of the gland is in many respects comparable to that which is to be observed during lactation in the adult female.

commences about the third or fourth month of pregnancy, and may be obtained by pressure carefully applied. This may be turned to useful account in diagnosing cases of concealed or doubtful pregnancy from cases of simple suppression of the catamenia; but it will not serve to distinguish true pregnancy from spurious, or from the distension of the uterus by tumours.* The vascularity of the gland continues to increase during pregnancy; and at the time of parturition its lobulated character can be distinctly felt. After the cessation of the catamenia from age, so that pregnancy is no longer possible, the lactiferous ducts continue open, but the milk-follicles become much reduced in size. The substance of the lobules gradually disappears, so that in old age only portions of the ducts remain, which are usually loaded with mucus; but the place of the lobules is commonly filled up by adipose tissue, so that the form of the breast is preserved. Sir A. Cooper notices a curious change, which he states to be almost invariable with age—namely, the ossification of the arteries of the breast, the large trunks as well as the branches, so that their calibre is greatly diminished or even obliterated.

768. The Mammary gland of the Male is a sort of miniature picture of that of the Female. It varies extremely in its magnitude; being in some persons of the size of a large pea; whilst in others it is an inch, or even two inches, in diameter. In its structure it corresponds exactly with that of the female, but is altogether formed on a smaller scale. It is composed of lobules containing follicles, from which ducts arise; and these follicles and ducts are not too minute to be injected, although with difficulty. The evolution of the gland goes on *pari passu* with that of the body, not undergoing an increase at any particular period; it is sometimes of considerable size in old age. A fluid, which is probably mucus, may be pressed from the nipple in many persons; and this in the dead body with even more facility than in the living. That the essential character of the gland is the same in the male as in the female is shown by the instances, of which there are now several on record, in which infants have been suckled by men (§ 748).†

769. Although the state of functional activity in the Mammary gland is usually limited to the epoch succeeding Parturition, yet this is not invariably the case; for numerous instances are on record, in which young women who

* See a valuable Paper by Dr. Peddie, 'On the Mammary Secretion,' in the "Edinb. Monthly Journal," Aug. 1848.

† The most curious fact, however, is, that even *Men* should occasionally be able to perform the duties of nurses, and should furnish an adequate supply of infantile nutriment. Several cases of this kind are upon record—see the case described by the Bishop of Cork, in the "Philosophical Transactions," vol. xli. p. 813: one mentioned by Sir John Franklin ("Narrative of a Journey to the Polar Sea," p. 157): and one which fell under the notice of the celebrated traveller Humboldt ("Personal Narrative," vol. iii. p. 58)—but one of the most recent and authentic is that given by Dr. Dunglison ("Human Physiology," 7th edit., vol. ii. p. 514.)—Dr. Dunglison also mentions that in the winter of 1849–50, an athletic man, twenty-two years of age, presented himself at the Jefferson Medical College at Philadelphia, whose left mamma, *without any assignable cause*, had become greatly developed, and secreted milk copiously.—It may be added that a lactescent fluid, apparently presenting the character of true milk, may frequently be expressed from the mammary glands of infants. (See "Dublin Medical Press," April 17, 1850.) "Professor Hall, of the University of Maryland, exhibited to his Obstetrical class, in the year 1837, a coloured man, fifty-five years of age, who had large, soft, well-formed mammæ, rather more conical than those of the female, and projecting fully seven inches from the chest; with perfect and large nipples. The glandular structure seemed to the touch to be exactly like that of the female. This man had officiated as wet-nurse for several years in the family of his mistress; and he represented that the secretion of milk was induced by applying the children entrusted to his care, to the breasts during the night. When the milk was no longer required, great difficulty was experienced in arresting the secretion. His genital organs were fully developed." Corresponding facts are also recorded of the male of several of the lower animals.

have never borne children, and even old women long past the period of child-bearing, have had such a copious flow of milk as to be able to act as efficient nurses.* In these cases, the strong desire to furnish milk, and continued irritation of the nipple by the infant's mouth, seemed to have furnished the stimulus requisite for the formation of the secretion, and it has been found that this is usually adequate to *restore* the secretion, after it has been intermitted for some months during the ordinary period of lactation, in consequence of disorder or debility on the part of the mother, or any other cause; so that where her condition renders it advisable that she should discontinue nursing for a time, the child may be withdrawn and the milk 'dried up,' with a confident expectation that the secretion may be reproduced subsequently.† Dr. M'William mentions in his Report of the Niger Expedition,‡ that the inhabitants of Bona Vista (Cape de Verde Island) are accustomed to provide a wet nurse in cases of emergency, in the person of any woman who has once borne a child and is still within the age of child-bearing, by continued fomentation of the mammæ with a decoction of the leaves of the *jatropha curcas*, and by suction of the nipple.

770. The secretion of *Milk* consists of Water holding in solution Sugar, various Saline ingredients, and the peculiar albuminous substance termed Casein; and having Oleaginous particles suspended in it. Its reaction is sometimes alkaline, sometimes neutral, and sometimes acid. Cows' milk is usually, and the milk of Carnivora always, acid,§ from the presence of free lactic acid. Human milk appears, however, to have a decidedly alkaline reaction when it is perfectly fresh; it soon, however, becomes acid. Its sp. gr. is 1032. Its index of refraction for light was found by Valentin‖ to be in different women 1·3494 on the third day after delivery, 1·3483 on the sixth day, and 1·3475 on the fifteenth day. The constitution of this fluid is made evident by the ordinary processes to which it is subjected in domestic economy. If it be allowed to stand for some time, exposed to the air, the greater part of the oleaginous globules come to the surface, being of less specific gravity than the fluid through which they are diffused: this is especially the case with the larger facetted globules, which have been hence distinguished as 'cream globules.' The *cream* thus formed does not, however, consist of oily particles alone; but includes a considerable amount of casein, with the sugar and salts of the milk. It has a sp. gr. of 1·024. These are further separated by the continued agitation of the cream; which, by rupturing the envelopes of the oil-globules separates it into *butter*, formed by their aggregation, and *buttermilk*, with a sp. gr. of 1034, containing the casein, sugar, &c. A considerable quantity of casein, however, is entangled with the oleaginous matter, and this has a tendency to decompose, so as to render the butter rancid; it may be separated by keeping the butter melted at the temperature of 180°, when the casein will fall to the bottom, leaving the butter pure and much less liable to change.—The milk, after the cream has been removed, still contains the greatest part of its casein and sugar. The amount of casein and of fat increases when milk is allowed to stand for twenty-four hours,

* A collection of such cases is given in Dr. Dunglison's "Human Physiology," 7th edit., vol. ii. p. 513.

† See an account of M. Trousseau's experience on this point, in "L'Union Médicale," 1852, No. 7; and Paper by Dr. Ballou in the "Amer. Journ. of Med. Sci.," Jan. 1852.

‖ Pflüger's "Archiv," Band xix. 1879, p. 85.

the former at the expense of the albumin,* and the latter under the influence of fungi. Thus Kemmerich found in colostrum (§ 772), immediately after withdrawal, 31¼ parts of casein, and 43½ parts of albumin, but after the lapse of 24 hours these proportions were reversed, the quantities being 42·4 of casein and 30·6 of albumin.† If it be kept long enough, a spontaneous change takes place in its composition; the milk sugar or lactose is converted into lactic acid by a process of fermentation induced by a small particular ferment, the Bacterium lactis, and this coagulates the casein, precipitating it in small flakes.‡ Hammarsten§ believes that the presence of milk sugar is not necessary to the change, and that the ferment itself does not give rise to a lactic acid fermentation. He holds that the curdling of milk is due not to the mere precipitation of casein, but to the formation of an insoluble casein by the splitting up of a previously soluble form. The same precipitation may be accomplished at any time by the addition of an acid; all the acids, however, which act upon albumin, do not precipitate casein, as will presently be pointed out in detail. The most effectual means of effecting this is by the dried stomach of a calf, known as *rennet*. This peculiar property of curdling milk is due to the presence of a distinct ferment, and does not depend upon the acid of the gastric juice, since it takes place when the milk is neutral or faintly alkaline. Neither is it due to the pepsin of the stomach, for infusions may be prepared which have no digestive action on albumin, whilst they possess powerful milk curdling properties. The power of curdling milk is not confined to the stomach of the calf, as it exists in a greater or less degree in the stomachs of a great number of the domestic animals. A similar ferment has recently been found in the pancreas and in the succus entericus by Dr. Roberts of Manchester.‖ In the case of the pancreas the rennet ferment exists in the pig, sheep, calf, ox, and fowl, and is distinct from Trypsin. The whey left after the curd has been separated contains a large proportion of the saccharine and saline matters which entered into the original composition of the milk; this may be readily separated by evaporation.

Fig. 374.

771. When Milk is examined with the Microscope, it is seen to be an emulsion, consisting of a large number of particles, of irregular size and form, suspended in a somewhat turbid fluid (Fig. 374); these particles vary in size from about the 1–12,700th to the 1–3040th of an inch; and they are termed 'milk-globules.' They are not affected by the mere contact of ether

or alkalies; but if these reagents are shaken with them, an immediate solution is the result. The same effect happens if they are first treated with acetic acid. Hence it is evident that the globules consist of oily matter, enclosed in an envelope of some kind; and an extremely delicate pellicle may, in fact, be distinguished, after the removal of the oily matter by ether, or after the globules have been ruptured and their contents pressed out, by rubbing a drop of milk between two plates of glass. No proof of the organization of this pellicle has, however, been detected; and it is probably to be regarded as the simple result of the contact of oil with albuminous matter.* —Besides these milk-globules, other globules of much smaller size are seen in milk; and these present the peculiar Brownian movement which is exhibited by molecules in general. Most of them seem to consist of oily matter not enclosed in an envelope, as they are at once dissolved when the fluid is treated with ether, but, according to the statements of Donné, it would seem that a portion of them are composed of casein, suspended, not dissolved, in the fluid.

772. The *Colostrum*, or milk secreted during the first week after delivery, is of a rich yellow colour, less fluid than the milk of a later period, of a higher specific gravity (1075), strongly alkaline, and containing large oil globules, a few irregular flakes, probably epithelium scales, a little granular matter like curd, and a small number of granular corpuscles, *the colostrum corpuscles* (Fig. 374, *a a*), the largest of which are about 1–500th part of an inch in diameter, an excess of milk sugar, and very little casein. It coagulates on being heated to about 163° F.† The granular corpuscles, when maintained at a temperature of 100° F., exhibit feeble amœboid movements (Stricker and Schwartz). They are probably epithelial cells of the mammary ducts, since they are nucleated cells more or less filled with milk globules, which they are capable of ejecting whilst they move. The chemical composition of the solids of the colostrum in the human female, as compared with the milk of a subsequent period, is well given in the following percentage Table by Dr. Tolmatscheff:‡—

	Age.	Temperament.	Casein & Album.	Fat.	Sugar.
On 4th day after delivery	23 ...	Fair, middle stature	... 4·188 ...	2·471 ...	4·33
„ 6th „ „	22 ...	Large, fair, strong	... 2·050 ...	3·177 ...	5·76
„ 15th „ „	22 ...	Large, dark, strong	... 2·077 ...	2·939 ...	5·90
„ 36th „ „	34 ...	Large, fair, strong	... 1·104 ...	1·713 ...	6·26

Physiologically considered,§ the most marked peculiarities of the colostrum in the cow are the concentration of nutritive matter in it; the greater facility with which it coagulates by rennet as compared with older milk, and its greater power of resisting change when exposed to the action of air. All of these are qualities which may be eminently servicable, viewing it as the first food of the young animal. Thus its easy coagulability may be adapted to the comparatively weak gastric juice of the young animal. The excess of sugar and inorganic salts which it contains, together with its power of remaining semi-fluid, may promote the removal of the meconium by causing it to act as a laxative, whilst its concentration as nutritive matter may permit it to fulfil the same office for the young mammal as the food-yolk for the oviparous vertebrate. According to Bernard,‖ the Colostrum of the Human female contains a very large quantity of albumin, since it coagulates *en masse* when it is heated. At a later period

* The presence of an albuminous envelope to the oil globules floating in milk has been called in question by Kehrer, "Archiv f. Gynæcol.," Band ii. 1871, p. 1 (see also Zahn, Pflüger's "Archiv," 1869, p. 598), but it is maintained by Schwalbe, Max Schultze's "Archiv," Band viii. p. 269.

† See also Bernard, "Leçons," vol. ii. 1859, p. 224.

‖ "Leçons," vol. ii. 1859, p. 224.

none can be discovered by this method; but if sulphate of magnesia be added, all the casein and the butter will be thrown down, and on filtration will be left on the filter with the sulphate of magnesia; the filtrate will then contain the albumins and the sugar of milk, and will coagulate on heat. All the larger globules of oil may be removed by repeated filtration; and the fluid is then nearly transparent. This, in fact, is the simplest way of separating the oleaginous from the other constituents of the milk, as but little casein then adheres to the former. The transparent fluid, which has passed through the filter, contains nearly the whole amount of the casein of the milk; but even in this fluid there are found globules too minute to be kept back by the filter, whose chemical reactions mark them as oleaginous.

773. We shall now consider the chemical characters of each of the foregoing ingredients.—The *Oleaginous* matter of milk principally consists of the ordinary components of fat—viz., palmitin, stearin, and olein; but it also contains another substance peculiar to it, designated as *butyrin*, to which the peculiar smell and taste of butter are due; this yields on saponification several volatile acids, of strong animal odour, to which Chevreul has given the names of butyric, caproic, caprylic, and capric acids. These peculiar acids are not only formed when the butyrin is treated with alkalies, but are produced by the ordinary decomposition of this principle, which is favoured by time and moderate warmth.—The *Casein** of Human milk, however, by some chemists regarded as only a combination of albumin with soda, and therefore called the Alkali Albuminate (§ 770), is usually said to be much less precipitable by acids than is that of the Cow; very commonly resisting the action of the mineral acids, and even that of the acetic (in such cases it may be thrown down by passing a current of carbonic acid gas through the acidified milk), but being always coagulated by rennet,† though the curd is long in collecting. Acetic acid without heat produces in Human milk a slow separation of soft, flaky coagula; but when heat is employed, a more perfect coagulation is produced by small than by large quantities of this acid. Gastric rennet does not seem to act upon casein if an alkali be present in more than a very minute quantity, it acts most energetically in a weakly acid solution. Pancreatic rennet curdles milk which contains as much as four grains of bicarbonate of soda to the ounce of milk: it also appears to curdle milk which is weakly acid more readily than one which has a neutral reaction.‡ In several of these particulars, as well as in its small proportional amount, the Casein of Asses' Milk bears a closer resemblance to that of Human milk than does that of the Cow. Milk also contains an albumin which closely resembles the serum albumin contained in blood; it may be obtained after the casein has been coagulated and filtered off, by exact neutralization of the milk and subsequent boiling. —Lactose, or the *Sugar of Milk*,§ which may be obtained by evaporating whey to the consistence of a syrup, and then setting it aside to crystallize, forms four-sided prisms, whose composition is $C_{12}H_{24}O_{12}$. It has a specific gravity of 1534, and a feebly sweet taste; it is insoluble in ether and absolute alcohol; slowly soluble in cold and more rapidly in boiling water. In many of its properties it bears a close resemblance to Glucose or Grape sugar, into which it is converted by the agency of dilute sulphuric or hydrochloric acid, or

§ For two simple methods of determining the quantity of sugar in milk, see Gschleidlen, "Pflüger's Archiv," Band xvi. (1878) p. 131.

by the acetic or citric acids. It is readily made to pass into the lactic and butyric fermentation by the appropriate ferments; but is with difficulty brought to undergo alcoholic fermentation.—The *Saline* matter contained in milk appears to be nearly identical with that of the blood; with a larger proportion of the phosphates of lime and magnesia, which amount to 2 or $2\frac{1}{2}$ parts in 1000. These phosphates are held in solution chiefly by the casein, which seems to have a power of combining with them even greater than that of albumin; the presence of a minute proportion of free alkali also assists their solution. A small portion of iron in the state of phosphate, together with the chlorides of potassium and sodium, and traces of potassium phosphates, magnesium phosphates, lecithin, cholesterin, alcohol, butyric, lactic and acetic acids; silicon and fluorin, odorous substances, may also be detected in milk.*

774. The proportion of these different constituents is liable to great variation from several causes. Thus, the whole amount of the solid constituents may vary from 86 to 138·6 parts in 1000; the difference being partly due to individual constitution, but in great part also to the amount and character of the ingesta. The average seems to be between 100 and 120 parts. The following Table† will serve to indicate the usual composition, as well as the ordinary variations occurring in Human milk :—

	Joly and Filhol.‡	Bödecker.	Griffith.	Becquerel and Vernois.	Simon.	Henry and Chevallier.	Brunner.§
Water	874·6	882·2	875·00	889·08	861·8—914·0	879·5	900
Sugar of Milk . .	68	64·6	61·76	43·64	39·2— 62·4	65·0	62·0
Fat	47·5	31·0	25·41	26·66	8·0— 54·0	35·5	17·3
Albumin, Casein, &c.	9·8	19·0	12·68	39·24	19·6— 45·0	15·2	6·3
Salts	1·1	3·3	1·55	1·38	1·6— 2·7	4·5	14·0

Schukowsky‖ gives 30 per 100 as the average proportion of oleaginous matters in the milk of Russian women. Milk contains about 3–7 per cent. of its volume of Gas, having a percentage composition of 55·15 of Carbonic acid, 40·56 of Nitrogen, and 4·29 of Oxygen. It further appears from the analyses of Simon, that the proportion of the different ingredients is liable to variation according to the time which has elapsed since parturition. The milk only acquires its normal characteristics some days after parturition; the colostrum corpuscles disappear within the first eight days. Milk does not retain the same composition throughout the whole period of lactation; thus the casein and butter increase up to the second month, and then diminish in quantity, the butter during the fifth month, and the casein during the tenth month; the sugar diminishes during the first month and increases from the eighth; lastly, the salts increase during the first five months and then progressively diminish. Milk which has remained in the gland is richer in fixed principles, and the last portions withdrawn are always richer in butter and casein, though the quantity of milk and the proportion of butter which it contains increase. Evening milk is said to be richer in solids, and to contain twice the amount of butter, and rather more casein than the morning milk.¶ —That some of the variations, moreover, are due to the character of the ingesta, and others to the external temperature, amount of exercise, and other circumstances affecting the individual, is proved by the inquiries of Dr. Playfair upon the Milk of the Cow. He has shown that the amount of butter

‖ Pflüger's "Archiv," 1874, Band viii. p. 597. See also Lowit for a comparison of the results obtained by analysing milk in the several ways recommended by Trommer, Hoppe-Seyler, and Schukowsky in Pflüger's "Archiv," (1874), Band ix. p. 65.

¶ Beaunis, "Nouv. Element. de Physiol. hum.," 1876, p. 141.

depends in part upon the quantity of oily matter in the food, and in part upon the amount of exercise which the animal takes and the warmth of the atmosphere in which it is kept: exercise and cold, by increasing the respiration, eliminate part of the oily matter in the form of carbonic acid and water; whilst rest and warmth, by diminishing this drain, favour its passage into the milk. The proportion of Casein, on the other hand, is increased by exercise. Dr. Playfair's experience on this head seems to correspond with the results of common observation in Switzerland; for where the cattle pasture in very exposed situations, and are obliged to use a great deal of muscular exertion, the quantity of butter yielded by them is very small, whilst the cheese is in unusually large proportion; but these same cattle, when stall-fed, give a large quantity of butter and very little cheese. It is quite possible, moreover, that particular breeds of cattle may yield milk of a richer quality than others. Thus, Vernois and Becquerel* found that Tyrolese, Dutch and Swiss cows gave milk containing from 7 to nearly 10 per cent. of butter, with much casein and albumin; whilst the cows in the immediate neighbourhood of Paris furnished a poor "green" or "beast" milk, containing only 3·6 or 3·7 per cent. of butter and but little casein. The total amount of solid matter in the milk diminishes with age, being most abundant in nursing women of from 15 to 20 years, and smallest in those of from 35 to 40 years of age. From 20–30 there is a decrease in the amount of casein and an increase in the sugar contained in the milk; the butter is present to the greatest extent from 15–20, after which it decreases.

775. The change which naturally takes place from the condition of Colostrum to that of true Milk, during the first week of lactation, is a very important one. The Colostrum, as already stated (§ 772), has a purgative effect upon the child, which is very useful in clearing its bowels of the meconium that loads them at birth; and thus the necessity of any other purgative is generally superseded. Occasionally, however, the *colostric* character is retained by the milk during an abnormally long period; and the health of the infant is then severely affected. It is important to know that this may occur, even though the milk may present all the usual appearances of the healthy secretion; but the microscope at once detects the difference.† The return to the character of the early milk, which has been stated to take place after the expiration of about twelve months, seems to indicate that Nature designs the secretion no longer to be encouraged; the mother's milk cannot then be so nutritious to the child as other food;‡ and every medical man is familiar with the injurious consequences to which she renders herself liable by unduly prolonging lactation.§ Cases are not unfrequent, however, in which the secretion continues as long as there is a demand for it; and sometimes quite independently of this. It is the habit, among some nations, to suckle the children until they are three or four years old, and to continue doing so even though another pregnancy should supervene;‖ so that the older child is only displaced by the arrival of another infant. And it seems to be

‡ On the whole subject of Infant Nutrition, the Author would strongly recommend the excellent little work of Dr. A. Combe, formerly referred to.

§ One of these, which has particularly fallen under the Author's notice, is debility of the retina, sometimes proceeding to complete amaurosis; this, if treated in time, is most commonly relieved by discontinuance of lactation, generous diet, and quinine.

‖ See Erman's "Travels in Siberia" (translated by Cooley), vol. ii. p. 527; and the "Narrative of the United States' Expedition," vol. ii. p. 138.

chiefly among those who have thus forced the mammary gland into a state of unnatural and persistent activity, that the spontaneous and irrepressible flow continues after the demand for it has ceased.*

776. It is very interesting to observe that Milk contains all the classes of principles which are required for human food—the Albuminous, the Oleaginous, the Saccharine, and the Mineral; and it is the only secreted fluid in which these all exist to any considerable amount. It is, therefore, the food most perfectly adapted for the young animal; and is the only single article supplied by Nature in which such a combination exists. Our artificial combinations will be suitable to replace it, just in proportion as they imitate its character; but in none of them can we advantageously dispense with milk, under some form or other. It should be remembered that the Saline ingredients of milk, especially the phosphates of lime, magnesia, and iron, have a very important function in the nutrition of the infant, affording the material for the consolidation of its bones, and for the production of its red blood-corpuscles; and any fluid substituted for milk, which does not contain these, is deficient in essential constituents. It is very justly remarked by Dr. Rees,† that, of all the secreted fluids, Milk is most nearly allied in its composition to Blood. The proportion of the different ingredients in the Milk of different animals is subject to considerable variation: and this fact is of much practical importance in guiding our selection, when good Human milk cannot be conveniently obtained for the nourishment of an infant. The first point to be inquired into, is the quantity of solid matter contained in each kind; this may be determined either by evaporation, or by the specific gravity of the fluid. The specific gravity of Human Milk is stated by Dr. Rees (loc. cit.) to vary between 1030 and 1035; others, however, have estimated it much lower. That of the cow appears to be usually about the same; that of the cream, however, being 1024, and that of the skimmed milk about 1035. The variation will in part depend (as in the case of the urine) upon the quantity of fluid ingested, and, in part, it is probable, upon the manner in which the milk is drawn; for it is well known to milkers, that the last milk they obtain is much richer than that with which the udder is distended at the commencement. The quantity of solid matter obtainable from Cow's Milk by evaporation, seems to be usually considerably greater than that yielded by Human Milk; and there is also a considerable difference in the relative proportions of their ingredients, there being far more casein and less sugar in the milk of the Cow than in that of the Human female. The following Table exhibits the average proportions of the different ingredients in the Milk of various animals from which that fluid is commonly obtained; these proportions, however, are liable to wide variations:—

	Woman. (Simon.)	*Cow.* (Simon.)	*Goat.* (Chevallier.)	*Sheep.* (Chevallier.)	*Ass,* (Simon.)	*Mare.* (Luiscius.)
Water	890	860	868	856	907	888
Solids	110	140	132	144	95	112
Butter	25	38	33	42	12	8
Casein	35	68	40	45	16	16
Sugar and Extractives	48	30	53	50	65	88
Fixed Salts	2	6	6	7		

It appears from this, that, whilst the milks of the Cow, Goat, and Sheep have a general correspondence with each other, those of the Ass and Mare are fluids of very dissimilar character, containing a comparatively small proportion of

* See case by Dr. Green, "New York Journ. of Med. and Surg.," Sept. 1844.

† "Cyclopædia of Anatomy and Physiology," Art. 'Milk.'

casein, and still less butter, but abounding in sugar. Hence it is that they are much more disposed to ferment than other milk; indeed the sugar of Mare's milk is so abundant, that the Tartars prepare from it a spirituous liquor, to which they give the name of *koumiss*. Although no milk more nearly approaches that of the Human female, in the proportion of its ingredients, than that of the Goat, its casein forms a peculiarly dense curd, which does not suit the stomach of the infant; besides which, the milk is tainted with the peculiar odour of the animal, which is more intense if the goat be dark-coloured. The milk of the Ass, though differing in the proportion of its ingredients, seems to bear a closer approximation in properties. The milk of the Cow will usually answer very well for the food of the infant, if care be taken to dilute it properly, according to the age of the child, and to add a little sugar. Where there is an apprehension of an early failure in the supply of Milk, the Author has found it advantageous to commence feeding the Infant once a day with this mixture, soon after the first month; the number of its meals may be progressively increased, until it becomes entirely independent of its parent, without any abrupt transition: and at the same time the proportion of water and of sugar may be diminished, in accordance with the natural change which takes place in the milk of the mother during the progress of lactation (§ 772). It must not, however, be supposed that human milk can be converted into cow's milk by the mere addition of 60 per cent. of water and about 2 per cent. of sugar, for the albuminous substances of the two kinds of milk present very different reactions. Thus, human milk is not coagulated by Acetic, Hydrochloric, Sulphuric or Nitric acids, either of which immediately cause the formation of large flakes and curds in the milk of the cow. On the whole, unless children are very carefully attended to, those fed on cow's milk or other artificial substitute for mother's milk are apt to grow up with signs of defective nutrition, indicated by anæmia and rickets.

777. In the alveoli of an actively secreting mammary gland (Fig. 373) some of the lining epithelial cells may be seen to contain one or more milk globules, each of which possesses its own albuminous coat, and lies in a vacuole in the cell. Similar globules may also be observed lying freely in the lumen of the alveoli, it is therefore probable that milk is formed as a secretion by the cells of the gland, and that it does not originate from their degradation and discharge. The albuminous coating of the milk globule is casein; it is produced in the cells by changes effected in their protoplasm under the action of a special ferment, which, according to Dähnhardt,* can be extracted from the gland tissue by means of glycerin. Kemmerich† has shown that such a conversion of albumin into casein is possible, since when milk is digested for some hours at the body temperature, the casein is increased, whilst the albumin undergoes a proportional decrease. The quantity of butter existing in milk exceeds many times the amount of fat ingested, it must therefore be formed within the organism. Heintz‡ believes that a portion of the fat may be simply withdrawn from the blood, since he detected in milk, olein, stearin and palmitin. Lactose is formed directly by the gland cells, probably from the albuminous substances which are brought to them by the blood, since a considerable quantity is found in the milk of carnivora living exclusively on a flesh diet. There is reason to believe that if, whilst the process of the secretion of milk is going on, it be suddenly checked, the retention of the material in the blood, or the re-absorption of the secreted fluid, is attended with injurious con-

* "Arch. f. Ges. Physiol.," iii. (1870), p. 586. † Ibid., ii. (1869), p. 401.
‡ "Ann. d. Chemie und Pharmacie," lxxxviii. p. 300.

sequences. Thus if, when the milk is first secreted, the child be not put to the breast, an accumulation takes place, which, if not relieved, occasions great general disturbance of the system. The narrowness of the orifices of the milk-tubes obstructs the spontaneous exit of the fluid, especially in *primiparæ;* the reservoirs and ducts become loaded: further secretion is prevented; and a state of congestion of the vessels of the gland, tending to inflammation, is induced. The accompanying fever is partly due, no doubt, to the local disturbance; but in part also, there seems reason to believe, to the re-absorption of the milk into the blood; this cannot but be injurious, since, although but little altered, the constitution of milk is essentially different, especially in regard to the quantity of crystallizable matter (sugar) which it contains.—Cases of the *vicarious* secretion of milk are not numerous; and in no instance is there any proof that the elements of the fluid were pre-existent in the blood. Some of the most curious are those in which it has been poured out from a gland in the groin; but it is probable that this was in consequence of the existence of a real repetition, in that place, of the true mammary structure; this being the situation of the mammæ in many of the inferior animals, of which the homologues in man are usually undeveloped.*

778. Of the quantity of Milk ordinarily secreted by a good Nurse, it is difficult to form a correct estimate;† since the amount which can be artificially drawn, affords no criterion of that which is secreted at the time of the 'draught' (§ 681). The quantity which can be squeezed from either breast at any one time, and which, therefore, must have been contained in its tubes and reservoirs, is about two ounces. The amount secreted is greatly influenced by the mental and physical condition of the female, and also by the quantity and character of the ingesta. In regard to the influence of the mental state upon this secretion, ample details have already been given (§ 682). With respect to the physical state most favourable to the production of an abundant supply of this important fluid, it may be stated generally, that sound health, a vigorous but not plethoric constitution, regular habits, moderate but not fatiguing exercise, and an adequate but not excessive amount of nutritious food, furnish the conditions most required.

779. The influence of various Medicines upon the Milk, is another important question which has not yet been sufficiently investigated. As a general rule, it appears that most soluble saline compounds pass into the milk as into other secretions; but there are many exceptions. Common salt, the sesqui-carbonate of soda, sulphate of soda, iodine, iodide of potassium, mercury, lead, antimony, arsenic, essence of anise, absinthe, oxide of zinc, tris-nitrate of bismuth, and sesqui-oxide of iron, the crucifera generally, and many odorous substances,‡ have been readily detected in the milk; and ordinary experience shows that the Human infant is affected by many of them when they are administered to the mother; thus the influence of mercurial medicines taken by the mother, in removing from the infant a syphilitic taint possessed by both, is well known. The vegetable purgatives, especially castor-oil, senna, and colocynth, have little effect upon the milk; hence they are to be preferred to the saline aperients, when it is not desired to act upon the bowels of the child.

* For case of vicarious secretion of milk, see "Bulletino delle Scienze Mediche," April, 1839; and "Brit. and For. Med. Review," Jan. 1840.

† For an estimate by M. Guillot, founded on the comparative weight of the Infant before and after lactation, see "L'Union Médicale," 1852, No. 16. The total amount considered by Mons. Guillot to be usually drawn in the twenty-four hours, varies from 32 oz. to 64 oz. (apoth.); but his estimates are vitiated by the extraordinary frequency of the lactations observed, the infant being put to the breast from 25 to 30 times in the twenty-four hours.

CHAPTER XIX.

OF THE DIFFERENT BRANCHES OF THE HUMAN FAMILY, AND THEIR MUTUAL RELATIONS.

1. *General Considerations.*

780. On taking a general survey of the Human race, it is natural, in the first place, that we should proceed to inquire into the evidence at present possessed of its antiquity, and into the physical and social conditions which prevailed in the most remote periods of which any information can be acquired; and secondly, that we should endeavour to ascertain whether the origin of the race is attributable to a single pair whose offspring have peopled the earth, or whether there may not have been a plurality of parents or of centres from which the remarkably different nations that are now in existence have sprung. The question of the remote Antiquity of Man, though long ago suggested, has only of late years, on account of the numerous facts which seem to lend support to it, awakened a lively spirit of philosophic inquiry. When our attention has been directed to it, however, it soon appears that no subject possesses a deeper interest than the relation in which Man stands to the organic world around him, both animal and vegetable: whether he was originally created with his corporeal powers, and the intellectual faculties to which they minister already developed to their highest extent, and capable of the greatest results that have been achieved in subsequent times; or whether he is not rather to be regarded as the crown and acme of a long process of development commencing with far simpler organisms, which, under the protracted operation of external agents, and in accordance with the law of *continuous descent with modification through natural selection*, whereby those animals that are the strongest and best adapted for the special conditions of life present at any time, supplant, and ultimately exterminate the less perfectly constituted, has at length culminated in a creature that even now, howsoever noble in reason and infinite in faculties, yet presents a transitory condition only to some more exalted phase of existence. The facts on which this opinion rests are of various character and weight, and a few only of the more important can here be alluded to. We have seen that in the earliest stages of the development of the embryo of the Human subject, which in this respect presents a character common to all animals, a single cell is alone discoverable; this receiving an accession of energy from the sperm-cell, and being placed under favourable conditions for the acquisition of the materials requisite for growth, soon undergoes sub-division; and in the cellular mass thus formed a differentiation of parts takes place, by which the various organs and tissues of the body are successively evolved. In the higher forms of the animal creation we have further seen that at certain transitory stages of development a close analogy exists with the permanent conditions of creatures occupying a lower position in the scale; and that, whilst throughout the whole a wonderful unity in the process is clearly discernible, each species presents certain characteristic features which are peculiar to itself. This, it is supposed, may have occurred in the history of the world. A few great types may have been originally formed, which, in the lapse of

ages, owing to the action of external agents, as light, heat, and food, and to the perpetuation of accidental varieties especially adapted to these external conditions, have gradually resulted in the infinitely varied species that now surround us.* With this extraordinary similarity in the process of development throughout the whole animal kingdom, which seems very difficult to account for upon the theory of a separate creation for each species, it cannot be a matter of surprise that close bonds of alliance should be found in the adult period of life even amongst the most dissimilar creatures. The Birds, for instance, appear to be a singularly well-defined and separate group; yet the researches of Mr. Parker† have shown that in their osseous system they possess affinities with every other class of the Vertebrata; so that, whilst presenting the closest analogies to Reptiles, and especially to the Lacertilian group, they anticipate, on the one hand, various Mammalian characters, and on the other recede, as it were, below Reptiles, retaining different Ichthyic points of structure, which are not, as a rule, found in that class. And thus it has ever been found that the more closely the structure of even the most aberrant forms of animal life has been investigated, the wider have been the affinities discovered, often explaining what was previously obscure in the structure of others, whilst at the same time the more complete has been the proof that no real isolation of a species, much less of a genus or family, exists. It is indeed probable—and this is a point on which Dr. Darwin lays great stress—that were it possible to reproduce the entire series of forms now become extinct, a regular gradation would be presented from the lowest to the highest; and hence that, as Sir Joseph Hooker has maintained,‡ we are indebted for our means of resolving plants into limitable genera and orders simply to the extinction of the forms by which they were originally connected. The reason that the intermediate links have not been discovered is owing essentially to the imperfection of the geological record. Of that great book, comparatively few leaves have as yet been deciphered; whilst even under the most favourable circumstances, and with the largest amount of information that can be obtained from this source, it is certain that the softness of the tissues of many animals will have presented an effectual obstacle to their preservation.§ It is obvious that if this mode of explanation of the production of species be extended to its utmost limits, we may reach the extreme of simplicity; for it may well be said that if a few types only are needed, these may again be reduced in number to a greater and still greater degree, until at length we arrive at that which is common to all at some stage of their existence—the

* For a full exposition of this theory, see Darwin, "On the Origin of Species by Means of Natural Selection," &c., 1859.

† See his Paper 'On the Osteology of the Gallinaceous Birds and Tinnamous,' in the "Trans. of the Zoological Society" for Nov. 25, 1862.

‡ "Introduction to the Flora of New Zealand," 1853.

§ The occurrence of a few cases where the conditions have been favourable, as in the instance of the Tellina of the Freshwater Chalk formation of Steinheim mentioned by Oscar Schmidt (in his "Descendenzlehre," 1873, p. 87) is highly suggestive in this point of view. Here the deposit from a small inland lake may be divided into about forty petrographically distinguishable layers, and throughout the whole series the varieties of Planorbis multiformis are distributed in such a manner that individual layers are characterized as successive strata by the exclusive occurrence, or by the predominance of one or more varieties which within the layer remain constant or slightly variable, but towards the limits of the next layer lead by transition to the succeeding forms. The forms diverge so greatly, and are so constant in the main zones, that in accordance with the old conchological practice they would be unreservedly claimed as species if the connecting links were not too conspicuous and the territory too circumscribed, and if the geological period—which must, however, be reckoned by thousands of years—were not considered too insignificant. Similar statements may be made in respect to the Ammonites.

single nucleated cell—a structure which comprehends the totality of the life of some animals and vegetables, and is constantly met with as the earliest stage of development of all; whilst the whole superstructure of both kingdoms may be considered to proceed from a gradual process of development and differentiation of this primary and most simple organization. It is but just to remark, however, that Prof. Owen, one of the best authorities on this subject, has advanced a different explanation of the origin of species. He states* that, "being unable to accept the volitional hypothesis, or that of impulse from within, or the selective force exerted by outward circumstances," he deems "that a minute tendency to deviate from parental type operating through periods of adequate duration is the most probable nature, or way of operation, of the secondary law, whereby species have been derived one from the other."

781. By those who embrace the developmental theory, numerous facts have been recently collected, tending in the first place to prove that Man has existed for many thousands of years upon the face of the earth; and secondly, that the more remote the period at which he can be proved to have existed, the ruder, more savage and degraded, both in a social and a structural or physical point of view, was his condition. In regard to the former point, very strong evidence has recently been obtained by the discovery of Human remains intermingled with those of extinct animals, as the Mammoth, Cave Bear, and woolly Rhinoceros, in the *breccias* of various caverns, as in those of Liége and Engis; whilst in other instances, where no bones have been discovered, perhaps in consequence of the practice of burning the dead, almost equally unexceptional evidence has been obtained from the discovery of works of art fashioned by Human hands, as in the flint implements found buried in the drift at Abbeville in Picardy and at St. Acheul near Amiens, and those found at Hoxne in Suffolk, and in Brixham Cave near Torquay.† In these instances the geological position of the remains, as well as the circumstance of their being accompanied by the bones of so many extinct animals, alike point to a remote antiquity. In particular, a very close investigation of those found at Moulin Quignon, near Abbeville, by M. Boucher de Perthes and others, has been made by Mr. Prestwich,‡ who has shown that, although some doubts may exist respecting the authenticity of the Human jawbone and some of the flint implements recently discovered there, yet that the genuineness of other flint implements cannot be doubted, and that the age of the gravel-beds in which they have been discovered is perfectly well determined as belonging to an early Quaternary or Post-pliocene period, dating before the excavation of the valley of the Somme, and consequently to a period when the physical character of the country wore a very different aspect from that which it now presents.

782. Nor can the circumstance be disregarded, that in the oldest existing monuments, as on those of Amenophis, of Horus, and of Rhameses,§ sculpture and painting, amongst the latest of the fine arts in their devolpment, had attained to so high a degree of perfection amongst the Egyptians, that the types of the Human race there depicted may still be referred to as excellent

portraitures of some of the still existing varieties—the Jew, the Mongol, and the Ethiopian being readily distinguishable. For this indicates, on the one hand, the wonderful permanence of particular types, and so far constitutes an argument against the Specific Unity of Man on the assumption that his duration upon the earth has not exceeded, as ordinarily computed, some 6,000 years; whilst if we estimate the period occupied in the progress to a high degree of civilization in these old times by the rate at which it has advanced in the history of modern European nations, we find it requisite to admit the lapse of a much longer period than is usually allowed, and of a long sequence of antecedent generations. In all the nations of Western Europe, in France, in England, in Germany alike, it has taken many centuries to rear the modern fabric of civilization; and the ultimate results obtained by ancient nations, however imperfectly they may be known to us, do not appear to be of so extraordinary a nature as to lead us to attribute to them a superior, if even an equal, measure of intellectual endowments with ourselves, nor on that account to admit that their progress in mental culture may have been more rapid.*

783. The evidence tending to show that the most ancient races of Man possessed a materially lower type of organization than those at present in existence, is not by any means sufficient to enable any general conclusions to be drawn respecting the truth of the developmental theory, or to show that there have been transitional links between the higher Apes and Man. In the most remarkable cranium yet discovered, that of the Neanderthal, which has been most carefully examined by Prof. Huxley, the forehead is indeed unusually low and retreating, the supra-orbital ridges prominent, and the bones remarkably thick. Yet its cubic capacity does not appear to be materially less than that of many crania that might be selected from modern nations; and hence, as Mr. Huxley adds, the first traces of the primordial stock whence Man has proceeded need no longer be sought by those who entertain any form of the doctrine of progressive development in the newest tertiaries, but must be looked for in an epoch more distant from the age of the Elephas primigenius (mammals) than that is from us.

784. Many interesting facts have recently come to light, which, whilst furnishing corroborative geological evidence of the antiquity of Man, afford important means of estimating the material and social conditions of his existence in these distant epochs. The most interesting evidence upon these points is derived from the Danish Peat Mosses. These, which are of considerable depth, varying from 30 to 40 feet or more, have been the result of the slow formation of ages; and from the extraordinary preservative power which they possess, have become the receptacles or depositaries of a series of objects, from which, by a process of inductive reasoning, the most valuable conclusions can be drawn. On the surface of the soil of Denmark at the present time there flourish magnificent forests of Beech trees, numerous trunks of which are found in the superficial layers of the Peat, mingled with those of other trees, as the Alder, the Aspen, and the Birch. With these are found various instruments constructed of iron, a metal requiring a considerable amount of technical skill in its extraction, partly on account of the chemical processes to which the ores have to be subjected, and partly on account of the extremely high temperature required for its fusion or welding. These tools are accompanied by the skulls of men presenting close analogies to the present Scandinavian type, of whom, indeed, they may be considered as the early ancestors.† Below the Beeches, the trunks of Oaks are found, and iron instruments cease to appear, being

* Sir Charles Lyell, "Antiquity of Man," p. 89.

† See also Rollestonand Greenwell "On British Barrows."

replaced by those of bronze. Sir John Lubbock* has adduced various considerations to show that these workers in bronze, which is composed of copper and tin, were of Eastern origin, and were perhaps allied to the modern Hindoo, with whom they agreed in the form of the head, in the practice of burning the dead, in their leading a pastoral and agricultural life, as evidenced by the associated remains of sheep, oxen, and pigs, and in using cylindrical as well as cubic dice. Still lower in the Peat the scene once more changes; the trunks of Pines now abound, and with these have been discovered crania belonging to a wholly different race—a race who were ignorant of even the simplest processes of metallurgy, and were only able to fashion, though often with great skill and ingenuity, a series of stone or flint instruments—hammer, chisel, saw, adze or dagger—and who were probably a hunting and fishing nation, burying their dead in tumuli or barrows. Additional information has been gained respecting this race, or the races, coeval with them, by the investigation of the Swiss Lake Habitations, the piles supporting which have been found in the lakes of Zurich, Constance, and Geneva; and still more by careful examination of the Danish "Kitchen-middings." In the former the same succession of Iron, Bronze, and Stone eras appear to have succeeded one another; whilst the latter seem to be refuse-heaps, composed of oysters, cockles, muscles, periwinkles, and other mollusca which have been thrown out around their habitations by men of the Stone period. The crania of this race are small and round, with overhanging eyebrows. The remains of dogs and various wild animals are found in the middings, which, with the canoes, and the bones of deep-sea fish, as the cod and herring, seem to show that this ancient people lived by hunting and fishing.

785. In pursuing the second branch of our inquiry, it is apparent that amongst the various tribes of Men which people the surface of the globe, and which are separated from all other animals by the characters formerly described (Chap. II.), there are differences of a very striking and important nature. They are distinguishable from each other, not only by their language, dress, manners, and customs, religious belief, and other acquired peculiarities, but by the physical conformation of their bodies; and the difference lies not merely in the colour of the skin, the nature of the hair, the form of the soft parts (such as the nose, lips, &c.), but in the shape of the skull and of other parts of the bony skeleton, which might be supposed to be less liable to variation. Now it is clearly a question of great scientific interest, as well as one that considerably affects the mode in which we regard the races that differ from our own, whether they are all of *one species*—that is, descended from the *same* or from *similar* parentage—or whether they are to be considered as *distinct species*, the first parent of the several races having had the same differences among themselves as those which are now exhibited by their descendants.

786. In order to arrive at a just conclusion on this subject, it is necessary to take a very extensive survey of the evidence furnished by a number of different lines of inquiry. Thus, in the First place, it is right to investigate what are the discriminating structural marks by which *species* are distinguished among other tribes of animals.—Secondly, it should be ascertained to what extent *variation* may proceed among races which are historically known to have had a common parentage, and what are the circumstances which most favour such variation.—Thirdly, the extreme variations which present themselves among the different races of Men, should be compared with those which occur among tribes of animals known to be of the same parentage; and it should be questioned, at the same time, whether the circumstances which favour the pro-

* "Natural History Review," 1861, p. 489.

duction of varieties in the latter case are in operation in the former.—Fourthly, where it is impossible to trace back distinct races to their origin, it is to be inquired how far agreement in physiological and psychological peculiarities may be regarded as indicating specific identity, even where a considerable difference exists in bodily conformation; and this test, if it can be determined on, has to be applied to Man.—Fifthly, it must be attempted by a detailed examination of the varieties of the Human race themselves, to ascertain whether their differences in conformation are constant: or whether there are not such occasional manifestations in each race, of a tendency to assume the characters of others, as to prevent any definite lines being drawn between the several tribes which together make up the (supposed) distinct species.—An investigation so comprehensive could not be followed out, even in the most cursory manner that would be consistent with utility, within the limits of the present work; and no more will be attempted, therefore, than an indication of the principal points of difference among the several Races of Men, and a statement of the results of inquiry into their degree of constancy in each of the principal groups which they have been thought to mark out.*

787. The differential characters on which those have relied who have sought to establish the existence of a *plurality of species* among Mankind, are both Anatomico-Physiological, and Psychological. Under the former head rank the colour of the Skin, the texture of the Hair, and the conformation of the bony Skeleton, especially the Skull. The latter consist in the superiority claimed for some races over others, in Intellectual power, and in Moral and Religious capacity. The former group will be the one first considered. The *Colour* of the skin exists in the Epidermis only; and it depends upon the admixture of *pigment* cells with the ordinary epidermic cells: all the varied hues presented by the different races of men being due to the relative amount of these cells, and to the particular tint of the pigment which they form. It would be easy, by selecting well-marked specimens of each race, to make it appear that colour affords a character sufficiently distinctive for their separation; thus, for example, the fair and ruddy Saxon, the jet-black Negro, the olive Mongolian, and the copper-coloured North-American, might be considered to be positively separated from each other by this character—propagated, as it seems to be, with little or no perceptible change, from generation to generation. But although such might appear to be the clear and obvious result of a comparison of this kind, yet a more careful and comprehensive survey tends to break down the barrier that would be thus established. For, on tracing this character through the entire family of Man, we find the isolated specimens just noticed to be connected by such a series of links, and the transition from one to the other to be so very gradual, that it is impossible to say where the lines are to be drawn between them. There is nothing here, then, which at all approaches to those fixed and definite marks, that are always held to be requisite for the establishment of specific distinctions among other tribes of animals.

788. But further, there is abundant evidence that these distinctions are far from being constantly maintained, even in any one race. For among all the principal subdivisions, *albinoism*, or the absence of pigment-cells, occasion-

* The whole of this investigation has been most elaborately, and in the Author's opinion most successfully worked out by Dr. Prichard, in his profound and philosophical Treatise on the "Physical History of Man." For a more concise view of Dr. Prichard's argument, with some additional considerations not embraced in it, the Author may refer to his own Article on the 'Varieties of the Human Species,' in the "Cyclop. of Anat. and Phys.," vol. iv.—See also Dr. R. G. Latham's "Natural History of the Varieties of Man;" and his shorter Essay on the 'Varieties of the Human Species,' in Orr's "Circle of the Sciences," vol. i.

ally presents itself; so that the fair skin of the European may present itself in the offspring of the Negro or of the Red man.* On the other hand, instances are by no means rare of the unusual development of pigment-cells in individuals of the fair-skinned races; so that parts of the body are of a dark red or brown hue, or even quite black. Such modifications may seem of little importance to the argument; since they are confined to individuals, and may be put aside as accidental. But there is ample evidence that analogous changes may take place in the course of time, which tend to produce a great variety of shades of colour, in the descendants of any one stock. Thus, in the great Indo-European family (part of the *Caucasian* race of Blumenbach), which may be unquestionably regarded as having had a common origin, we find tribes with fair complexion, yellow hair, and blue eyes—others presenting the xanthous or olive hue—and others decidedly black. A similar diversity may be seen among the American races, which are equally referable to one common stock: and it exists to nearly the same extent among the African nations, which appear to be similarly related to each other. It may be freely admitted that among European colonists settled in hot climates such changes do not present themselves within a few generations; but in many well-known instances of earlier colonization, they are very clearly manifested. Thus the wide dispersion of the Jewish nation, and their remarkable isolation (maintained by their religious observances, from the people among whom they live, render them peculiarly appropriate subjects for such observations; and we accordingly find that the brunette complexion and dark hair, which are usually regarded as characteristic of that race, are frequently superseded, in the Jews of Northern Europe, by red or brown hair and fair complexion; whilst the Jews who settled in India some centuries ago, have become as dark as the Hindoos around them.

789. The relation of the complexions of the different Races of Mankind to the climates they respectively inhabit, which is established by an extended comparative survey of both, leads to the general conclusion that the intertropical region of the earth is the principal seat of the darkest races, whilst the region remote from the tropics is that of the fairer races; and that the climates approaching the tropics are generally inhabited by nations which are of an intermediate complexion. It is important to observe, however, that no regular gradation of tint can be observed in passing from the equatorial to the polar regions. M. Paul Broca† has particularly pointed out that the Esqui-

* A very curious example of *change of colour* in a Negro has been recorded on unquestionable authority.—The subject of it was a negro slave in Kentucky, æt. 45, who was born of black parents, and was himself perfectly black until 12 years of age. At that time a portion of the skin, an inch wide, encircling the cranium just within the edge of the hair, gradually changed to white; also the hair occupying that locality. A white spot next appeared near the inner canthus of the left eye; and from this the white colour gradually extended over the face, trunk, and extremities, until it covered the entire surface. The complete change from black to white occupied about ten years; and but for his hair, which was crisped or woolly, no one would have supposed at this time that his progenitors had offered any of the characteristics of the Negro, his skin presenting the healthy vascular appearance of that of a *fair-complexioned* European. When he was about 22 years of age, however, dark *copper coloured* or brown spots began to appear on the face and hands; but these remained limited to the portions of the surface exposed to light. About the time that the black colour of his skin began to disappear, he completely lost his sense of smell; and since he has become white, he has had measles and hooping-cough a second time. (See Dr. Hutchinson's account of this case in the "Amer. Journ. of Med. Sci.," Jan. 1852.)—A case of partial disappearance of the black colour of the Negro's Skin was brought by Dr. Inman before the Zoological Section of the British Association at Liverpool, Sept. 1854.

† In his Paper 'On Hybridity,' in M. Brown-Séquard's "Journal de la Physiologie" for 1858, p. 462. See for many analogous instances, J. Craufurd, in the "Transactions of the Ethnological Society," vol. i. p. 364.

maux of Greenland, the Lapps and Finns of Europe, and the Samoyedes and Kamschatkans of Asia, all of them nations inhabiting the most northern regions of the habitable globe, present a deep olive complexion, dark straight hair, and dark eyes; being considerably deeper in hue than the Chinese, Burmese, Cochin-Chinese, and Malays, although these are situated so much nearer the equator, and are exposed to the rays of a far fiercer sun. The same conclusion is forced upon us by a survey of the various nations inhabiting the western shores of America; for if we trace them in succession from Behrings Straits to Patagonia, we shall find that under the same latitude as Norway there dwells a race whose colour is yellowish-brown, mixed with red; under that of England a perfectly white race (Vancouver's Islanders), under that of France a red race (Oregon), under that of Spain and Algeria a black race (California.) From thence as far as the equator, under the same latitude as Guinea and Soudan, are races of a merely brown tint, much lighter than the inhabitants of those regions. Lastly, the races which occupy the littoral region extending from the equator to Terra del Fuego, present a brown tint, becoming lighter as the colder regions are approximated; but are suddenly succeeded, under the rigorous climate of Patagonia, by one or more blackish or altogether black races. To these observations it may be added that high mountains, and countries of great elevation, are generally inhabited by people of a lighter colour than are those of which the level is low, such as swampy or sandy plains upon the sea-coast. These distinctions are particularly well seen in Africa, where the tropics almost exactly mark out the limits of the black complexion of the inhabitants; and where the deepest hue is to be seen among the Negroes of the Guinea Coast, whose residence unites both the conditions just mentioned, whilst the mountainous regions in their immediate vicinity are inhabited by tribes of a much lighter aspect.

790. The nature of the *Hair* is, perhaps, one of the most permanent characteristics of different races, and a division has been established between the *Ulotrichi* with crisp or woolly hair, and the *Leiotrichi* with smooth hair. With few exceptions (Andaman Islanders) the *Ulotrichi* are also dolichocephalous. They are represented by the Negroes and Bushmen of Central and Southern Africa, and the Negritos of the Malay Peninsula and Archipelago, and of the Papuan Islands. The *Leiotrichi* are divisible into the Australioid group, the Mongoloid group, the Xanthochroic group (Slavonians, Teutons, Scandinavians), and the Melanochroic group (Iberians and black Celts of Western Europe).* In regard to its colour the same statements apply as those just made with respect to the colour of the skin; the variety of hue being given by pigment-cells, which may be more or less developed under different circumstances. But it has been thought that its *texture* affords a more valid ground of distinction; and it is commonly said that the substance which grows on the head of the African races, and of some other dark-coloured tribes (chiefly inhabiting tropical climates), is *wool* and not hair. This, however, is altogether, a mistake; for microscopic examination clearly demonstrates that the hair of the Negro has exactly the same structure with that of the European, and that it does not bear any resemblance to wool, save in its crispness and tendency to curl. Moreover, even this character is far from being a constant one; for, whilst Europeans are not unfrequently to be met with whose hair is nearly as crisp as that of the Negro, there is a great variety amongst the Negro races themselves which present every gradation, from a completely crisp (or what is termed woolly) hair, to merely curled or even flowing locks.† A

* See Huxley, "The Anatomy of Vertebrated Animals."

† It is a very common mistake, especially in the United States, to consider *Negro*

similar observation holds good in regard to the natives of the islands of the great Southern Ocean, where some individuals possess crisp hair, whilst others of the same race have it merely curled.

791. It has been supposed that varieties in the configuration of the *Skeleton* would afford characters for the separation of the Human races, more fixed and definite than those derived from differences in the form, colour, or texture of the soft parts which clothe it: and attention has been particularly directed to the *skull* and the *pelvis*, as affording such characters. It has been generally laid down as a fundamental principle, that all those nations which are found to resemble each other in the shape of their heads must needs be more nearly related to each other than they are to tribes of Men which differ from them in this particular. But if this principle be rigorously carried out, it will tend to bring together races which inhabit parts of the globe very remote from each other, and which have no other mark of affinity whatever; whilst, on the other hand, it will often tend to separate races which every other character would lead us to bring together. It is to be remembered, moreover, that the varieties in the conformation of the skeleton, presented by the breeds of domesticated animals, are at least equal to those which are manifested in the conformation and colour of their soft parts; and we might reasonably expect, therefore, to meet with similar variations among the Human races. It is probable, however, that climate has not so much influence in producing such changes in the configuration of the body, as the peculiar habits and mode of life of the different races; and Dr. Prichard has pointed out a very remarkable relation of this kind, in regard to the principal types of form presented by the Skull. These differ from each other to such an extent, that if the antero-posterior diameter be taken at 100 the transverse diameter varies from 98 or 99 to 62. The number expressing the proportion of the transverse to the longitudinal diameter of the brain case is termed the cephalic index. Those people who possess crania with a cephalic index of 80 and above are called brachycephali; those with a lower index are dolichocephali.*

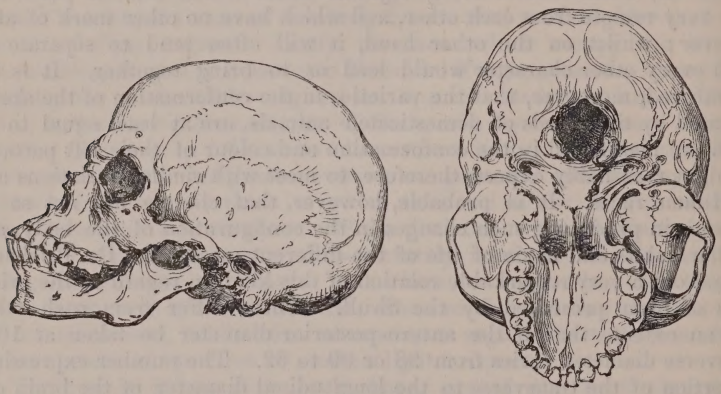
792. Among the rudest tribes of Men, hunters and savage inhabitants of forests, dependent for their supply of food on the accidental produce of the soil, or on the chase—among whom are the most degraded of the African nations, and the Australian savages—a form of head is prevalent which is most aptly distinguished by the term *prognathous*, indicating a prolongation, or forward-extension of the jaws (Fig. 375). This character is most strongly marked in the Negroes of the Gold Coast, whose skulls are usually so formed as to give the idea of lateral compression. The temporal muscles have a great extent, rising high on the parietal bones; the cheek-bones project forward, and not outward; the upper jaw is lengthened and projects forwards, giving a similar projection to the alveolar ridge and to the teeth; and the lower jaw has somewhat of the same oblique projection, so that the upper and lower incisor teeth are set at an obtuse angle to each other, instead of being nearly in parallel planes, as in the European. From the shape of the upper jaw alone would result a marked diminution in the facial angle, measured according to the method of Camper; but this diminution is far from being

as synonymous with *African*. So far is this from being the fact, that, as Dr. Latham justly remarks, "the true Negro area, the area occupied by men of the black skin, thick lips, and woolly hair, is exceedingly small; as small in proportion to the rest of the continent, as the area of the district of the stunted Hyperboreans is in Asia, or that of the Lapps in Europe."

* Huxley, "Anatomy of Vertebrated Animals," p. 495. See also P. Broca, "On Anthropology;" Rolleston and Greenwell, op. cit.; Flower, 'Lectures' in "British Med. Journal," vol. i. 1879.

sufficient to approximate the Ethiopian races to the higher Apes, as some have supposed it to be. Independently of the diminution of the facial angle resulting from the projection of the upper jaw, it is quite certain that in the typical prognathous skull there is a want of elevation of the forehead; but it does not appear that there is a corresponding diminution in the capacity of the cranial cavity, the retreating form of the forehead being partly due to the general elongation of the skull in the antero-posterior direction. Nor is it true, as stated by some, that the position of the foramen magnum in the Negro is decidedly behind that which it holds in the European, in this respect approaching that of the Apes; since, if due allowance be made for the projection of the upper jaw, this aperture is found to have the same position

Fig. 375.



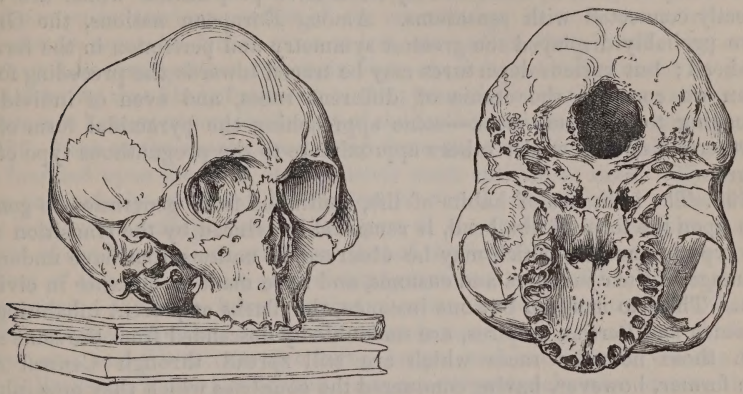
Profile and basal views of the *Prognathous Skull* of a Negro.

in the prognathous skull as in the oval one—namely, exactly behind the transverse line bisecting the antero-posterior diameter of the base of the cranium. The prognathous skull is further remarkable for the large development of the parts connected with the organs of sense, especially those of smell and hearing. The aperture of the nostrils is very wide, and the internal space allowed for the distribution of the olfactory nerve is much larger than in most European heads; the posterior openings of the nasal cavity are not less remarkable for their width than the anterior. The external auditory meatus is also peculiarly wide and spacious; and the orbital cavities have been thought to be of more than ordinary capacity—but this last is by no means a constant character.

793. A second type of cranial conformation, very different from the preceding, belongs principally to the nomadic races which wander with their herds and flocks over vast plains; and to the tribes which creep along the shores of the Icy Sea, and live partly by fishing, and in part on the flesh of their reindeer. This form, designated by Dr. Prichard as the *pyramidal* (Fig. 376), is typically exhibited by various nations of Northern and Central Asia; and is seen in an exaggerated degree in the Esquimaux. Its most striking character is the lateral or outward projection of the zygoma, which is due to the form of the malar bones. These do not project forwards and downwards under the eyes, as in the prognathous skull; but take a lateral or outward direction, forming, with the zygomatic process of the temporal bone, a large rounded sweep or segment of a circle. From this, in connection with the narrowness of the forehead, it results that lines drawn from the zygomatic

arches, touching the temples on either side, instead of being parallel (as in Europeans), meet over the forehead, so as to form with the basis a triangular figure. The upper part of the face being remarkably flat, the nose also being flat, and the nasal bones, as well as the space between the eyebrows, being nearly on the same plane with the cheek-bones, the triangular space bounded

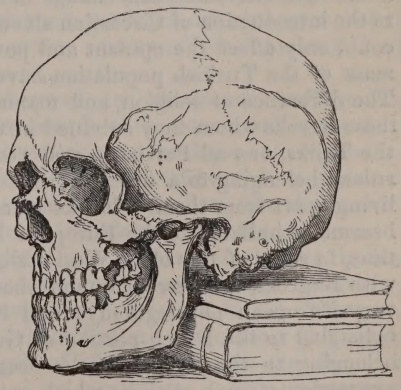
Fig. 376.



Front and basal views of the *Pyramidal Skull* of an Esquimaux.

by these lines may be compared to one of the faces of a pyramid. The orbits are large and deep; and the peculiar conformation of the bones which surround it, gives to the aperture of the lids an appearance of obliquity—the inner angle seeming to be directed downwards. The whole face, instead of presenting an oval form, as in most Europeans and Africans, is of a lozenge-shape. The greater relative development of the zygomatic bones, and of the bones of the face altogether, when compared with the capacity of the cranium, indicates in the pyramidal skull a more ample extension of the organs subservient to sensation; the same effect being thus produced by lateral expansion, as by the forward extension of the facial bones in the prognathous skulls.

Fig. 377.



Oval Skull of a European.

794. The most civilized races—those which live by agriculture and the arts of cultivated life—all the most intellectually-improved nations of Europe and Asia—have a shape of the head which differs from both the preceding, aud which may be termed the *oval* or *elliptical*. This at once approves itself as a more symmetrical form, no part having an excessive prominence; whilst, on the other hand, there is nowhere an appearance of undue flattening or compression. The head is altogether of a rounder shape than in the other varieties, and the forehead is more expanded; while the maxillary bones and the zygomatic arches are so formed as to give the face an oval shape, nearly on a plane with the forehead and cheek-bones, and not projecting towards the

lower part. Owing to the more perpendicular direction of the alveolar processes, the front teeth are fixed in planes which are nearly or quite parallel to each other. The principal features in this form of cranium are thus of a negative character; the chief positive distinction is the large development of the cranial cavity, and especially the fulness and elevation of the forehead, in proportion to the size of the face; indicating the predominance of the intellectual powers over those merely instinctive propensities which are more directly connected with sensations. Among European nations, the Greeks have probably displayed the greatest symmetry and perfection in the form of the head; but various departures may be traced towards the preceding forms, when we compare the crania of different races, and even of individuals, belonging to the same stock—some approaching the pyramidal form of the Northern Asiatics, whilst others approximate to the prognathous type of the Negro.

795. The influence of habits of life, continued from generation to generation upon the form of the head, is remarkably evinced by the transition from one type to another, which may be observed in nations that have undergone a change in their manners and customs, and have made an advance in civilization. Thus, to mention but one instance, the Turks at present inhabiting the Ottoman and Persian empires, are undoubtedly descended from the same stock with those nomadic races which are still spread through Central Asia. The former, however, having conquered the countries which they now inhabit, eight centuries since, have gradually settled-down to the fixed and regular habits of the Indo-European race, and have made corresponding advances in civilization; whilst the latter have continued their wandering mode of life, and can scarcely be said to have made any decided advance during the same interval. Now the long-since-civilized Turks have undergone a complete transformation into the likeness of Europeans; whilst their nomadic relatives retain the pyramidal configuration of the skull in a very marked degree. Some have attributed this change in the physical structure of the Turkish race to the introduction of Circassian slaves into the harems of the Turks; but this could only affect the opulent and powerful amongst the race; and the great mass of the Turkish population have always intermarried among themselves. The difference of religion and manners must have kept them separate from those Greeks whom they subdued in the new Ottoman countries; as in Persia, the Tajiks, or real Persians, still remain quite distinct from their Turkish rulers, belonging to a different sect among the Mussulmans, and commonly living apart from them.—In like manner, even the Negro head and face may become assimilated to the European by long subjection to similar influences; thus, in some of our older West Indian Colonies, it is not uncommon to meet with Negroes, the descendants of those first introduced there, who exhibit a very European physiognomy; and it has even been asserted that a Negro belonging to the Dutch portion of Guiana may be distinguished from another belonging to the British settlements, by the similarity of the features and expression of each to those which respectively characterize his masters. The effect could not be here produced by the intermixture of bloods, since this would be made apparent by alteration of colour.—But not only may the pyramidal and prognathous types be elevated towards the elliptical; the elliptical may be degraded towards either of these. Want, squalor, and ignorance have a special tendency to induce that diminution of the cranial portion of the skull, and that increase of the facial, which characterize the prognathous type; as cannot but be observed by any one who takes an accurate and candid survey of the condition of the most degraded part of the

population of the great towns of this country, but as is seen to be pre-eminently the case with regard to the lowest classes of Irish immigrants.* A certain degree of retrogression to the pyramidal type is also to be noticed among the nomadic tribes which are to be found in every civilized community. Among these, as has been remarked by a very acute observer,† "According as they partake more or less of the purely vagabond nature, doing nothing whatsoever for their living, but moving from place to place, preying on the earnings of the more industrious portion of the community, so will the attributes of the nomad races be found more or less marked in them; and they are all more or less distinguished for their high cheek-bones and protruding jaws;" thus showing that kind of mixture of the pyramidal with the prognathous type, which is to be seen among the lowest of the Indian and Malayo-Polynesian race.

796. Next to the characters derived from the form of the head, those which are founded upon the form of the *pelvis* seem entitled to rank. These have been particularly examined by Professors Vrolik and Weber. The former was led, by his examinations of this part of the skeleton, to consider that the pelvis of the Negress, and still more that of the female Hottentot, approximates to that of the Simiæ in its general configuration; especially in its length and narrowness—the iliac bones having a more vertical position, so that the anterior spines approach one another much more closely than they do in the European; and the sacrum also being longer and narrower. On the other hand, Professor Weber‡ concludes, from a more comprehensive survey, that no particular figure is a permanent characteristic of any one race. He groups the principal varieties which he has met with, according to the form of the upper opening into oval, round, four-sided, and wedge-shaped. The first of these is most frequent in the European races; the second, among the American races; the third, most common among the Mongolian nations, corresponds remarkably with their form of head; whilst the last chiefly occurs among the races of Africa, and is in like manner conformable with the oblong compressed form usually presented by their cranium. But although there are particular shapes which are most prevalent in each race, yet there are numerous individual deviations of such a nature that every variety of form presents itself occasionally in any given race.

797. Other variations have been observed by anatomists, between the different races of Mankind, in the relative length of the bones, and in the shape of thel imbs; but these also seem to have reference to the degree of civilization, and to the regularity of the supply of wholesome nutriment. It is generally to be observed that the races least improved by civilization, like the uncultivated breeds of animals, have slender, lean, and elongated limbs; this may be especially remarked in the natives of Australia. In nearly all the less civilized races of Men, the limbs are more crooked and badly-formed than the average of those of Europeans; and this is particularly the case in the Negro, the bones of whose legs bow outwards, and whose feet are remarkably flat. It has been generally believed that the length of the fore-arm in the Negro is much greater than in the European, as to constitute a real character of approximation to the Apes. The difference, however, is in reality extremely slight; and is not at all comparable with that which exists between the most uncultivated races of Men and the highest Apes. And in regard to all the peculiarities here alluded to, it is to be observed that they can only be

* See the "Dublin University Magazine," No. xlviii.

† Mr. Henry Mayhew, in "London Labour and the London Poor," p. 2.

‡ "Die Lehre von den Ur- und Racenformen der Schaedel und Becken des Menschen," Düsseldorf, 1830.

discovered by the comparison of large numbers of one race with corresponding numbers of another; for individuals are found in every tribe, possessing the characters which distinguish the majority of the other race. Such peculiarities, therefore, are totally useless as the foundation of *specific* characters; being simply variations from the ordinary type, resulting from causes which might affect the entire race as well as individuals.—The connection between the general form of the body, on the one hand, and the degree of civilization (involving the regular supply of nutriment) on the other, is made apparent, not merely by the improvement which we perceive in the form, development, and vigour of the frame, as we advance from the lowest to the most cultivated of the Human race; but also by the degradation that is occasionally to be met with in particular groups of the higher tribes, which have been subjected for several generations to the influence of depressing causes. Of such degradation, occurring under circumstances that permit its successive steps to be traced, we have a remarkable example in the conversion of certain tribes of the Hottentot race into Bushmen; and there is very strong ground for the belief that similar influences have operated at a more remote period, in the production of the peculiar characters of the Guinea-coast Negroes and Australian Bushmen.

798. Independently, however, of the obvious modifying influence of external circumstances, much allowance must be made for that *tendency to variation*, which presents itself, more or less, in all those races of animals which possess such a constitutional capability of adaptation to changes in climate, habits of life, &c., as enables them to live and flourish under a variety of conditions. Thus we find that the offspring of any one pair of domesticated animals do not all precisely agree among themselves, or with their parents, either in bodily conformation or in psychical character; but that *individual* differences, as they are termed, exist among them. Now, as this tendency to variation cannot be clearly traced to any influence of external circumstances, it is commonly distinguished by the term 'spontaneous;' but as there is no effect without a cause, and as the widest differences of this kind present themselves in those races which are most obviously amenable to the influence of external conditions, we seem justified in attributing them to agencies operating unostensibly upon the parents, either previously to their intercourse, or at the time of coition (§ 725), or in the female during the period of utero-gestation (§ 728). The difference between wild and domesticated animals in regard to *colour* affords a very good illustration of this general fact; for the uniformity among the former is no less remarkable than the want of constancy among the latter; and whilst variety of colour soon gives place to uniformity, when domesticated races return in any inconsiderable degree towards their primitive state,* it very speedily develops itself in races which are undergoing the converse process.†

799. Now it is by taking advantage of those 'spontaneous' departures from the ordinary type, which present features of value to the breeders of domesticated animals, that *new races* are developed from time to time among these; any strongly marked peculiarity which thus appears in only a single individual, being usually transmitted to some of its offspring, and being almost certainly

* This has been especially noticed in the dogs, horses, cattle, sheep, and hogs introdueed by the Spaniards into South America.

† Thus, Mr. T. Bell informs us ("British Quadrupeds," 2nd edit., p. 203), that an Australian bitch, or dingo, in the Zoological Gardens, had a litter of puppies, the father of which was also of that breed; both parents had been taken in the wild state, both were of the uniform reddish-brown colour which belongs to the race, and the mother had never bred before; but the young, generated in confinement, and in a half-domesticated state, were all more or less spotted.

perpetuated when *both* parents are distinguished by it, as happens when the products of the first procreation become capable of breeding with each other.*—Now there can be no hesitation in admitting, that the tendency to the so-called 'spontaneous' variation prevails in the Human race to a greater degree than in any other; since we find most remarkable diversities in features, complexion, hair, and general conformation, among the offspring of the same parentage; whilst more special modifications of the ordinary type, such as the possession of six fingers on each hand and of six toes on each foot are of no unfrequent occurrence. Under ordinary circumstances, these modifications tend to disappear as often as they occur; the free intermixture of those members of the race which possess them, with those which depart less from the ordinary type, tending to merge them in the general average. But there can be no reasonable doubt that if the same kind of segregation were practised among Mankind, which is adopted by the breeders of animals for the purpose of perpetuating a particular variety—if, for example, the members of a six-fingered family were to intermarry exclusively with one another—any such variety would be permanently established as a new race. Now if it be borne in mind that the influence of a scanty population, in the early ages of the Human race, by isolating different families from each other, and causing inter-marriages among even the nearest relatives, would have been precisely the same with that which is now exercised by the breeders of animals, we see one reason why the varieties which *then* arose should have a much greater tendency to self-perpetuation than those which *now* occasionally present themselves. And when, too, it is borne in mind, that the change in external conditions induced by migration would thus operate not only upon the parents but upon the offspring, and would have a continual influence in so modifying the constitution of the latter that the peculiarities thus acquired by them would be transmitted in yet greater intensity to their progeny, there is no real difficulty in accounting, upon the strictest physiological principles, for the widest of those departures from one common type of conformation, which we encounter in our survey of the different Races of Mankind.†

800. Hence we are led to conclude, that, so far as regards their Anatomical structure, there is no such difference among them as would justify to the Zoologist the assertion of their distinct origin. But further, although the comparison of the structural characters of the Human races does not furnish any positive evidence of their descent from a common stock, it justifies the assertion that even if their stocks *were* originally distinct, there could have been no essential difference between them; the descendants of any one such stock being able to assume the characters of another. This, as already remarked, can be proved by historical evidence in regard to a sufficient number

* See the history of the introduction of the *ancon* breed of sheep, characterized by a peculiar conformation of its limbs, in Massachussetts, given by Col. Hutchinson in the "Phil. Trans." for 1813.—A similar account was subsequently given by Prof. Owen (in a Lecture delivered before the Society of Arts, Dec. 10, 1851), respecting the recent introduction of a new breed of merino sheep, distinguished for the long, smooth, straight, and silky character of the wool, and now known as the *Mauchamp* breed.—In both instances, the breed originated in the spontaneous appearance of a male lamb possessing the peculiarities in question; from its offspring such a selection was made by the breeder, as enabled him to bring together males and females, both of which were distinguished by them; and in their progeny, the peculiarities uniformly appeared.

† For a masterly digest of the analogical evidence furnished by the changes known to have been thus produced among domesticated animals, and of the modifications which particular tribes of men can be shown to have undergone within the historic period, see Dr. Prichard's "Physical History of Mankind," and his "Natural History of Man;" see also the summary given by the Author in the "Cyclop. of Anat. and Physiol.," vol. iv. pp. 1301—1339; and Darwin, "The Variation of Animals and Plants under Domestication," 1868.

of tribes, to justify the same assertion with respect to others, whose languages, customs, habits of thought, &c., have an affinity strong enough to warrant us in regarding them as descendants of the same stock, whilst their physical conformation is widely different. Each principal geographical area, which is so isolated from others as to render it probable, *à priori*, that its population has extended from one centre—such as the Continent of Africa, or America—contains races of very diversified physical characters, whose linguistic affinities make it almost certain that they must have had a common descent; and thus, in whatever mode the types of the principal varieties are selected, they are found to be connected by so gradual a series of intermediate or transitional forms, that it is impossible to draw any such line of demarcation between them, as would be required by a soundly-judging Naturalist for the boundary of distinct species.

801. A very important confirmation of this view is afforded by the essential agreement which exists among the different Races of Mankind in regard to their Physiological history; the variations which they present not being greater than those which we meet with between the different individuals of any one race. Thus, we not only find the average duration of life to be the same (making allowance for circumstances which are likely to induce disease), but the various epochs of life such as the times of the first and second dentition, the period of puberty, the duration of pregnancy, the intervals of the catamenia, and the time of their final cessation—present a marked general uniformity, such as does not exist among similar epochs in the lives of species that are nearly allied but yet unquestionably distinct. Further, the different races of Mankind are all subject to the same diseases, both sporadic, endemic, and epidemic; the only exceptions being those in which the constitution of the race has *grown to* a certain set of influences (as that of the Negro to the malaria which generate certain pernicious fevers in the European), producing an hereditary immunity in the race, which is capable of being acquired by individuals of other races, by a process of acclimatization commenced sufficiently early.*—The most important physiological test, however, of specific unity or diversity, is that furnished by the Generative process. It may be considered as a fundamental fact, alike in the Vegetable and in the Animal kingdom, that *hybrid* races originating in the sexual connection of individuals of two different *species*, do not tend to self-perpetuation; the hybrids being nearly sterile with each other, although they may propagate with either of their parent-races, in which the hybrid race will soon merge; whilst, on the other hand, if the parents be themselves *varieties* of the same species, the hybrid constitutes but another variety, and its powers of reproduction are rather increased than diminished, so that it may continue to propagate its own race, or may be used for the production of other varieties, almost *ad infinitum*. It appears that, among

* This view of the immunity of the Negro race from certain forms of fever which are very fatal to Europeans, is justified, the Author believes, by all the facts known upon the subject. Much may be set down, as he is assured by Dr. Daniell, to the better adaptation of the Negro habits of life to their climate; and Europeans who exercise due caution (especially in regard to the functions of the skin), may preserve an immunity scarcely less complete. Dr. Daniell himself, having been taken prisoner by one of the Negro tribes at an early age, and having spent two years among them, seems to have been thoroughly acclimatized; and has subsequently passed many years on the most unhealthy parts of the coast, without experiencing any severe attacks of illness, and in the enjoyment of very good general health.—It is sometimes maintained that the Negro race possesses such a complete exemption from the Yellow Fever of the United States as marks its specific difference; such, however, is not constantly the case, since Negroes occasionally suffer from it; and their *comparative* immunity seems fairly attributable to the constitutional peculiarity *acquired* by their African progenitors, and capable of being acquired by Europeans also.

Plants, hybrids originating between undoubtedly distinct species, sometimes reproduce themselves for two or three generations, but do not continue beyond the fourth. Amongst animals, the limits of hybridity between parents of distinct species are more narrow, since the hybrid is totally unable to continue its race with one of its own kind;* and although it may propagate with one of its parent-species, the progeny will of course approach in character to the pure breed, and the race will speedily merge into it. In Animals, as among Plants, the mixed offsprings originating from different races within the limits of the same species generally *exceed* in vigour, and in the tendency to multiply, the parent-races from which they are produced, so as to gain ground upon the older varieties, and gradually to supersede them. In this manner, by the *crossing* of the breeds of our domesticated animals, many new and superior varieties have been produced. The general principle is, then, that beings of distinct *species*, or descendants from stocks originally different, cannot produce a mixed race which shall possess the capability of perpetuating itself; whilst the union of *varieties* has a tendency to produce a race superior in energy and fertility to its parents.—The application of this principle to the Human races leaves no doubt with respect to their specific unity; for, as is well known, not only do all the races of men breed freely with each other, but the mixed race is generally superior in physical development, and in tendency to rapid multiplication, to either of the parent stocks; so that there is much reason to believe that, in many countries, the mixed race between the Aborigines and European colonizers will ultimately become the dominant power in the community. This is especially the case in India, South America, and Polynesia.

802. The question of *Psychical* conformity or difference among the Races of Mankind, is one which has a most direct bearing upon the question of their specific unity or diversity; but it has an importance of its own, even greater than that which it derives from this source. For, as has been argued with great justice and power,† the real Unity of Mankind does not lie in the consanguinity of a common descent, but has its basis in the participation of every race in the same moral nature, and in the community of moral rights, which hence becomes the privilege of all. "This is a bond which every man feels more and more the farther he advances in his intellectual and moral culture, and which in this development is continually placed upon higher and higher ground: so much so that the physical relation arising from a common descent is finally lost sight of, in the consciousness of the higher moral obligations." It is in these obligations, that the moral *rights of men* have their foundation; and thus, "while Africans have the hearts and consciences of human beings, it could never be right to treat them as domestic cattle or as wild fowl, if it were ever so abundantly demonstrated that their race was but an improved species of ape, and ours a degenerate kind of god."—The Psychical comparison of the various Races of Mankind is really, therefore, in a practical point of view, the most important part of the whole investigation; but it has been, nevertheless, the one most imperfectly pursued, until the inquiry was taken up by Dr. Prichard. The mass of evidence which he has accumulated on this subject, however, leaves no reasonable doubt that no more "impassable barrier" really exists between the different races with respect to this, than in

* One or two instances have been stated to occur in which a Mule has produced offspring from union with a similar animal; but this is certainly the extreme limit, since no one has ever maintained that the race can be continued farther than the second generation without admixture with one of the parent species. See also Darwin "On the Variations of Plants and Animals under Domestication."

† See the "New Quarterly Review," No. xv. p. 131; and an Article by Prof. Agassiz in the "Christian Examiner," Boston (N.E.), 1850.

regard to any of those points of ostensible diversity which have been already considered; the variations in the positive and relative development of their respective psychical powers and tendencies, not being greater, either in kind or degree, than those which present themselves between individuals of our own or of any other race, by some members of which a high intellectual and moral standard has been attained. The tests by which we recognize the claims of the outcast and degraded of our own or of any other 'highly-civilized' community, to a common humanity, are the same as those by which we should estimate the true relation of the Negro, the Bushman, or the Australian, to the cultivated European. If, on the one hand, we admit the influence of want, ignorance, and neglect, in accounting for the debasement of the savages of our own great cities—and, if we witness the same effects occurring under the same conditions among the Bushmen of Southern Africa (§ 812)—we can scarcely hesitate in admitting, that the long-continued operation of the same agencies has had much to do with the psychical as well as the physical deterioration of the Negro, Australian, and other degraded races. So, on the other hand, if we cherish the hope that the former, so far from being irreclaimable, may at least be brought-up to the standard from which they have degenerated, by means adapted to develop their intellectual faculties and to call forth the higher parts of their moral nature, no adequate reason can be assigned why the same method should not succeed with the latter, if employed with sufficient perseverance. It will be only when the effect of education, intellectual, moral, and religious, shall have been fairly tested by the experience of *many generations*, in conjunction with the influence of a perfect equality in civilization and social position, that we shall be entitled to speak of any essential and constant psychical difference between ourselves and the most degraded beings clothed in human form. All the evidence which we at present possess leads to the belief, that under a vast diversity in degree and in modes of manifestation, the same intellectual, moral, and religious *capabilities* exist in the Races of Mankind; so that, whilst we may derive from this conformity a powerful argument for their Zoological Unity as a species, we are also directly led to recognize their community of moral nature with ourselves, and to admit them to a participation in our own rights.

803. Most important assistance is afforded in the determination of the real affinities of different Races, by the study of their *Languages*. This, however, is a department of the inquiry so far beyond the limits of Physiological science that it must be here dismissed with a bare mention of those results, to which the zealous pursuit of it by a large number of philosophic Philologists seems undoubtedly to tend.—There can be no reasonable doubt that, as a general principle, the affinities of races are more surely indicated by their languages than by their physical features; and the experienced philologist is generally able to discriminate those resemblances, which may have arisen out of the introduction of words or of modes of construction from the one into the other, by conquest, commercial intercourse, or absolute intermixture, from those which are the result of a community of origin. And thus are supplied those means of tracing the past history of races, which are seldom afforded by written records, or even (at least with any degree of certainty) by traditional information.* It is to be borne in mind that the affinities of languages are indicated, not merely by verbal resemblance, but by the similarity of their modes of grammatical construction, or the methods by which the relation between different words that constitute sentences is indicated. The most positive evidence is of course afforded, when a conformity exists both in the

* See, however, Dr. E. B. Tylor's "Primitive Culture."

vocabularies and in the *modes of construction* of two languages; but it frequently happens that although the conformity exists in regard to one of these alone, yet the evidence which it affords is perfectly satisfactory. Thus, there are many cases in which the vocabularies are so continually undergoing important changes (the want of written records not permitting them to acquire more than a traditional permanence), that their divergence becomes so great, even in the course of a few generations, as to prevent tribes which are by no means remotely descended from a common ancestry, from understanding one another; whilst yet the system of grammatical construction, which depends more upon the grade of mental development and upon habits of thought, exhibits a remarkable permanence. Such appears to be true of the entire group of American languages; which seem, as a whole, to be legitimately referable to a common stock, notwithstanding their complete verbal diversity. On the other hand, when two languages or groups of languages differ greatly in construction, but present that kind of verbal correspondence on which the philologist feels justified in placing most reliance (namely, an essential conformity in those 'primary words' which serve to represent the universal ideas of a people in the most simple state of existence), that correspondence may be held to indicate a community of origin, if it can be proved that it has not been the result of intercourse between the two families of nations subsequently to their first divergence, and if it seems probable on other grounds that their separation took place at a period when as yet the grammatical development of both languages was in its infancy. Such appears to have been the case with certain of those groups of languages whose distinctness can be traced back historically for the longest period.*—It is evident, then, that Philological inquiry must be looked to as one of the chief means of determining the question of radiation from a *single* centre or from *multiple* centres; and it is a remarkable fact, that the linguistic affinity and the conformity in physical characters frequently stand in a sort of complemental relation to each other, each being the strongest where the other is weakest; so that, by one or other of these links of connection, a close relationship is indicated between all those families of nations under which the several races appear to be most naturally grouped.

2. *General Survey of the Principal Varieties of the Human Species.*

804. The distribution of the Races of Mankind under five primary varieties, according to their respective types of cranial conformation, as first proposed by Blumenbach, is still so commonly received, notwithstanding the distinct proof which has been given of the fallacious nature of its basis, that it will be desirable to explain his terms, and at the same time to show how far the information subsequently acquired has tended to modify his arrangement.—The first of these varieties, which is considered to be distinguished by the possession of the *oval* or *elliptical*† type of cranial conformation, was designated *Caucasian* by Blumenbach, on two grounds; first, because he considered the

* The changes, or stages of growth and development, through which all languages probably pass have been traced in a most interesting manner by Prof. Max Müller, in his "Lectures on the Science of Language" 1861: see Lectures ii. and viii.

† Now generally termed dolichocephalic, from δολιχός, long, and κεφαλή, head; in opposition to brachycephalic, from βραχύς, short, and κεφαλή (§ 790). According to Retzius, the majority of the people of *Western Europe* are dolichocephalic and orthognathic (ὀρθός, upright, and γνάθος, jaw); whilst the brachycephalic is the prevalent form of the skull throughout the great extent of *Eastern Europe*. He regards the Hindoos, Arian Persians, Arabs, and Jews, with the Tungusians and Chinese, as being examples of *Asiatic* dolichocephali, the last two being prognathic (πρό, forwards, and γνάθος, jaw), the former orthognathic; whilst the Samoyedes, Turks, Circassians, Afghans, Lascars, Tartars, Mongolians (both of Asiatic Russia and

Caucasian people (of whom the Georgians and Circassians are the best known examples) as presenting its physical characters in the greatest perfection; and second, because it was supposed that the Caucasian range of mountains might be regarded as the centre or focus of the races belonging to it. Neither of these ideas, however, is correct; for whilst the oval form of cranium is presented with fully as great beauty and symmetry by the Greeks, it seems now to be almost certainly determinable by the evidence of language, that the Georgian and Circassian nations are really of Mongolian origin, and consequently have no direct relation or affinity with the other nations usually ranked as belonging to this variety; and the evidence of history and tradition, so far from pointing to the Caucasian range as the original centre of radiation of the race, accords with that of language in assigning its locality much nearer to Central Asia. It would be most desirable, therefore, that some other designation should be substituted for that given by Blumenbach; were it not that the present state of our knowledge requires the entire abandonment of his doctrine, that the races agreeing in this type of conformation are mutually connected by community of descent. For, even within the limits of Europe, we find at least two nations—the Turks, and the Magyars or true Hungarians (§ 807)—whose crania are characteristically oval, and which are yet undoubtedly of Mongolian origin; and although some allowance must be made, in regard to the change which has taken place among the former, for the influence of intermixture, with other races, yet there is no reason to believe that any such influence has operated among the Magyars, whose blood seems to have been transmitted with remarkable purity from the time when they settled in Hungary about ten centuries since. In Asia, we find this type presented not merely by the Persian and other Indo-European races, but also by the Syro-Arabian and by the larger proportion of the inhabitants of Hindostan; yet the Syro-Arabian races are more nearly related to the African stock (§ 806) than to that from which most of the present inhabitants of Europe have sprung; and there is good reason to believe that the great mass of the existing inhabitants of India are of Mongolian descent (§ 807). It will be necessary, therefore, to consider the nations which present the so-called Caucasian type of cranial conformation under several distinct heads. No uniformity exists amongst them in regard to *colour;* for this character presents every intermediate gradation between the fair and florid tint, with light red or auburn hair, of the Northern European, to the dusky or even black hue of the races bordering on or lying between the Tropics. The hair is generally long and flexible, with a tendency to curl; but considerable variety presents itself with regard to this particular. The conformation of the features approaches more or less closely to that which we are accustomed to regard as the type of beauty.

805. The first place, in a more natural distribution of the Human Races, must undoubtedly be given to that which is designated by Dr. Prichard as the *Aryan*, and which is often termed the *Indo-European;* including the collective body of European nations, with the Persians,* Afghans, and certain

Mongolia), and Malays, are all prognathic brachycephali, and constitute the prevailing type. On the continent of Australia and in Van Diemen's Land, all the savage tribes are prognathic dolichocephali. See his 'Glance at the present state of Ethnology with reference to the Form of the Skull,' in the "Medico-Chir. Rev." for 1860, vol. xxv. p. 503, and vol. xxvi. p. 215.

* The modern Persians are a very mixed race, in which Turkish and Arab elements largely participate. The most perfect representatives of the original stock (whose purity of descent seems to have been maintained from the time of their original migration into their present locality, by the physical obstacles which have cut them off from intercourse with their nearest neighbours) are believed to be the Kafirs of Kafirstan, a fair-skinned, light-

other nations of the south-western portion of the Asiatic continent,* near to which their original focus appears to have been. The great bond of connection between these nations, lies in their languages; which, in spite of great diversities, present a certain community of character that is recognised by every philologist. The family which is most dissimilar to the rest (the typical Celt contrasting remarkably with the types of the Germanic group, both in physical conformation and in psychical characters) is that formed by the *Celtic* nations: but these are undoubtedly, like the others, of Eastern origin, as was first shown by Dr. Prichard;† though they appear to have detached themselves from the common stock at an earlier period in the development of its language. The *Indo*-Germanic languages are obviously all formed upon the same base with the ancient Sanskrit, if not upon the Sanskrit itself; and they are united alike by community in many of the most important 'primary words,' and by general similarity in grammatical construction. The existing Lettish or Lithuanian dialect presents a very near approach to the original type; and the Old Prussian, a dialect spoken as late as the sixteenth century, had a still closer alliance to the ancient Zend or Median, which seems to have been a very early derivation from the Sanskrit, and which is the basis of the language now spoken in Persia.—But there is evidence that, notwithstanding the mutual affinities of the Indo-Germanic languages, every one of them has been modified by the introduction of extraneous elements; thus, in those of Western Europe, there is a considerable admixture of Celtic; whilst in others there are traces of more barbaric tongues. In fact, there can be little doubt that Europe had an indigenous population, before the immigration of the Indo-German or even of the Celtic tribes; and of this population it seems most probable that the Lapps and Finns of Scandinavia, and the Euskarians (or Basques) of the Biscayan provinces, are but the remnant. The former of these tribes, which is undoubtedly of Mongolian origin, once extended much farther south than at present; and with regard to the latter, whose nearest linguistic affinities are also with the tongues of High Asia, there is ample historical proof that they had formerly a very extensive distribution through Southern Europe. It would not seem improbable, then, that the advance of the Indo-European tribes from the south-east corner into Central Europe, separated that portion of the aboriginal (Mongolian) population which they did not absorb or destroy, into two great divisions; of which one was gradually pressed northward and eastward, so as to be restricted to Finland and Lapland; and the other southward and westward, so as to be confined at the earliest historic period to a part of the peninsula of Spain and the South of France, gradually to be driven before the successive irruptions of the Celts, Romans, Arabians, and other nations, until their scanty remnant found an enduring refuge in the fastnesses of the Pyrenees.‡—The Indo-Germanic race is unquestionably that which has exercised the greatest influence on the civilization of the Old World; and it seems indubitably destined to acquire a similar influence in

haired race inhabiting the impracticable mountain country on the watershed between the Oxus and the north-western sources of the Indus. The Tajiks of Bokhara also keep up the ancient lineage and language, although their country is ruled by people of Turkish descent.

* The population of Hindostan has been commonly accounted as belonging to this division; but the more intimate the knowledge attained of its character and langages, the more does it lead to the conclusion that the great mass of this population is really of Mongolian descent (§ 808).

† "On the Eastern Origin of the Celtic Nations," 1831.

‡ This view, which was suggested by the Author in the "Brit. and For. Med. Rev.," Oct. 1847, without the knowledge that it had been elsewhere propounded, has been put forth with considerable confidence by Dr. Latham ("Varieties of Man," 1850), as having originated with Arndt and been adopted by Rask, distinguished Scandinavian ethnologists.

those newly-found lands which have been discovered by its enterprise. With scarcely an exception, as Dr. Latham has justly remarked, the nations belonging to it present an *encroaching* frontier; there being no instance of its permanent displacement by any other race, save in the case of the Arab dominion in Spain, which has long since ceased; in that of the Turkish dominion in Turkey and Asia Minor, which is evidently destined to expire at no distant period, being upheld for merely political purposes by extraneous influence; and in that of the Magyars in Hungary, who only maintain their ground through their complete assimilation to the Indo-Germanic character. It is a remarkable fact, that in most cases in which this race extends itself into countries previously tenanted by people of an entirely different type, the latter progressively decline and at last disappear before it, provided the climate be such as enables it to maintain a vigorous existence; this is pre-eminently the case in North and South America, in Australia, in New Zealand, and in many of the smaller Polynesian islands. And where the climate is less favourable to the perpetuation of the race in its purity, an intermixture with the native blood frequently gives origin to a mixed race, which possesses the developed intellect of the one, and the climatic adaptiveness of the other, and which appears likely ultimately to take the place of both.

806. The *Syro-Arabian* or *Semitic* nations agree with the preceding in general physical characters, but differ entirely in the structure of their language, and for the most part in vocabulary also, though recent researches seem to indicate that certain *roots* of the Semitic and Indo-Germanic languages have a decided affinity. It seems quite certain, however, that the linguistic affinities of the Semitic nations are rather with the *African* than with the Indo-European races; and so strong is the link of connection thus established, that by Dr. Latham they are ranked with the former under the general designation *Atlantidæ*,* whilst Mr. Norris, whose authority upon all such subjects is deservedly great, is strongly disposed (as he has himself informed the Author) to consider them an *essentially African* people.—The original seat of this race, however, is commonly reputed to have been that region of Asia which is intermediate between the countries of the Indo-European and of the Egyptian races; having as its centre the region watered by the great rivers of Mesopotamia. Several of the nations primarily constituting this group have become extinct, or nearly so; and the *Arabs*, which originally formed but one subdivision of it, have now become the dominant race, not only throughout the ancient domain of the the Syro-Arabian nations, but also in Northern Africa. In the opinion of Baron Larrey, who had ample opportunities for observation, the skulls of the Arabian race furnish, at present the most complete type of the human head; and he considered the remainder of the physical frame as equally distinguished by its superiority to that of other races of men. The different tribes of Arabs present very great diversities of colour, which are generally found to coincide with variations in climate. Thus, the Shegya Arabs, and others living on the low countries bordering on the Nile, are of a dark brown or even black hue; but even when quite jetty, they are distinguished from the Negro races by the brightness of their complexions, by the length and straightness of their hair, and by the regularity of their features. The same may be said of the wandering Arabs of Northern Africa; but the influence of climate and circumstances is still more strongly marked in some of the tribes long settled in that region, whose descent may be traced to a distinct branch of the Syro-Arabian stock,

* See his "Varieties of Man," 1850, p. 469.

namely, the *Berber*, to which belong the Kabyles of Algiers and Tunis, the Tuaryks of Sahara, and the Guanches or ancient population of the Canary Isles. Amongst these tribes, whose affinity is indisputably traceable through their very remarkable language, every gradation may be seen, from the intense blackness of the Negro skin, to the more swarthy hue of the inhabitants of the South of Europe. It is remarkable that some of the Tuaryk inhabitants of particular Oases in the great desert, who are almost as insulated from communication with other races as are the inhabitants of islands in a wide ocean, have hair and features that approach those of the Negroes; although they speak the Berber language with such purity as to forbid the idea of the introduction of these characters by an intermixture of races. The *Jews*, who are the only remnants now existing of the once powerful Phœnician tribe, and who are now dispersed through nearly every country on the face of the earth, present a similar diversity; having gradually assimilated in physical characters to the nations among which they have so long resided (§ 787).

807. The second primary division of the Human family, according to the arrangement of Blumenbach, is that commonly termed *Mongolian*. The real Mongols, however, constitute but a single and not very considerable member of the group of nations accepted under this designation, which is, therefore, by no means an appropriate one. The original seat of these races appears to have been the great central elevated plain of Asia, in which all the great rivers of that continent have their sources, whatever may be their subsequent direction. Taken as a whole, this division is characterized by the pyramidal form of the skull, whose antero-posterior diameter scarcely exceeds the parietal, and by the broad flat face and prominent cheek-bones; by the flattening of the nose, which is neither arched nor aquiline; by the eyes being drawn upwards at their outer angle; by the xanthous or olive complexion, which sometimes becomes fair, but frequently swarthy; by the scantiness and straightness of the hair, and deficiency of beard; and by lowness of stature. These characters, however, are exhibited in a prominent degree only in the more typical members of the group, especially those inhabiting Northern and Central Asia; and may become so greatly modified, as to cease altogether to be recognizable. Such a modification has been remarkably effected in the case of a part of the *Turkish* people, now so extensively distributed. All the most learned writers on Asiatic history are agreed in opinion that the Turkish races are of one common stock; although at present they vary in physical characters, to such a degree that, in some, the original type has been altogether changed. Those which still inhabit the ancient abodes of the race, and preserve their pastoral nomadic life, present the physiognomy and general characteristics which appear to have belonged to the original Turkomans; and these are decidedly referable to the so-called Mongolian type. Before the Mahommedan era, however, the Western Turks or Osmanlis had adopted more settled habits, and had made considerable progress in civilization; and their adoption of the religion of Islam incited them to still wider extension, and developed that spirit of conquest, which, during the Middle Ages, displayed itself with such remarkable vigour. The branches of the race, which, from their long settlement in Europe, have made the greatest progress in civilization, now exhibit in all essential particulars the physical characters of the European model; and these are particularly apparent in the conformation of the skull.—Another marked departure from the ordinary Mongolian type is presented by the Hyperborean tribes inhabiting the borders of the Icy Sea; these have for the most part a pyramidal skull, but their complexion is swarthy and their growth is peculiarly stunted; and they form the link that

connects the ordinary Mongolidæ with the Lapps and Finns of Europe on one side, and with the Esquimaux of North America on the other. The Ugrian division, which migrated towards the north-west at a very early period, planted a colony in Europe, which still tenants the northern Baltic countries, forming the races of *Finns* and *Lapps*. In the time of Tacitus, the Finns were as savage as the Lapps; but the former, during the succeeding ages, became so far civilized as to exchange a nomadic life for one of agricultural pursuits, and have gradually assimilated with the surrounding people; whilst the Lapps, like the Siberian tribes of the same race, have ever since continued to be barbarous nomades, and have undergone no elevation in physical characters. The same division gave origin to the *Magyars* or Hungarians; a warlike and energetic people, unlike their kindred in the North; in whom a long abode in the centre of Europe has, in like manner, developed the more elevated characters, physical and mental, of the European nations.

808. The nations inhabiting the south-eastern and southern portions of Asia, also, appear to have had their origin in the Mongolian or Central-Asiatic stock; although their features and form of skull by no means exhibit its characteristic marks, but present such departures from it as are elsewhere observable in races that are making advances in civilization. The conformity of the Mongolian type is most decidedly shown by the nations (collectively termed *Seriform* by Dr. Latham) which inhabit China, Thibet, the Indo-Chinese peninsula, and the base of the Himalayan range; these are associated by certain linguistic peculiarities which distinguish them from all other races; that primitive condition of human speech, in which there is a total absence of inflections indicative of the relation of the principal words to one another, being apparently preserved with less change in the tongues of these people than in those of any other. The Chinese may be physically characterized as Mongolians softened down; and in passing from China towards India through the Burmese empire, there is so gradual a transition towards the ordinary Hindoo type, that no definite line of demarcation can be anywhere drawn. —The inhabitants of the great peninsula of Hindostan have been commonly ranked (as already remarked) under the Caucasian race; both on account of their physical conformity to that type, and also because it has been considered that the basis of their languages is Sanskritic. It is certain, however, that this conclusion is incorrect with regard to a very large proportion of the existing population of India; and there is strong reason to believe that no part of it bears any real relation of affinity to the Indo-European group of nations, except such as may be derived from a slight intermixture. Thus, the *Tamulian*, which is the dominant language of *Southern* India, is undoubtedly not Sanskritic in its origin (although containing an infusion of Sanskritic words), but more closely approximates to the Seriform type; and many of the hill tribes, in different parts of India, speak peculiar dialects, which, though mutually unintelligible, appear referable to the same stock. Now it is among this portion of the population of India that the greatest departure presents itself from the Caucasian type of cranial formation, and the closest conformity to the Mongolian; the cheek-bones being more prominent, the hair coarse, scanty, and straight, and the nose flattened; sometimes, also, the lips are very thick, and the jaws project, showing an approximation to the prognathous type. In the opinion of Dr. Latham and Mr. Norris, the various dialects of *Northern* India (of which the *Hindostani* is the most extensively spoken) are to be regarded as belonging, in virtue of their fundamental nature, to the same group with those of High Asia, notwithstanding the large infusion of Sanskritic words which they contain; this infusion having

been introduced at an early period by an invading branch of the Arian stock, of whose advent there is historical evidence, and whose descendants the ordinary Hindoo population have been erroneously supposed to be. According to this view, then, the influence of the Arian invasion upon the language and population of Northern India was very much akin to that of the Norman invasion upon those of England; the number of individuals of the invading race being so small in proportion to that of the indigenous population as to be speedily merged in it—not, however, without contributing to an elevation of its physical characters; and a large number of new words having been in like manner introduced, without any essential change in the type of the original language. And thus the only distinct traces of the Arian stock are to be found in the Brahminical caste, which preserves (though with great corruption) the original Brahminical religion, and which keeps up the Sanskrit as its classical language; it is certain, however, that this race is far from being of pure descent, having intermingled to a considerable extent with the ordinary Hindoo population. There is but little to remind us of the Mongolian type in the countenances of the Hindoos, which are often remarkable for a symmetrical beauty that only wants a more intellectual expression to render them extremely striking; some traces of it, however, may perhaps be found in the rather prominent zygomatic arches which are common amongst them; but the cranial portion of the skull presents no approach to the pyramidal type, being often very regularly elliptical. There is a remarkable difference in the colour of the different Hindoo tribes; some being nearly as dark as Negroes, others more of a copper colour, and others but little darker than the inhabitants of Southern Europe.*

809. According to the usual mode of dividing the Human family, the *Ethiopian* or *Negro* stock is made to include all the nations of Africa to the southward of the Atlas range. But, on the one hand, the Hottentots and Bushmen of the southern extremity constitute a group which is strongly distinguished by physical characters from the rest of the African nations; so, again, the region north of the Great Desert is mostly occupied by *Semitic* tribes (§ 806); the scattered population of the Great Desert itself is far from being Negro in many of its features; the valley of the Nile, at least in its middle and lower portions, including Egypt, Nubia, and even Abyssinia, is inhabited by a group of nations which may be designated as Nilotic, and which presents a series of gradational transitions between the Negroes and Kaffres and the Semitic races; a large portion of the area south of the Equator is occupied by the Kaffre tribes and their allies, which cannot be truly designated as Negroes; so that the true Negro area is limited to the western portion of the African continent, including the alluvial valleys of the Senegal, the Gambia, and the Niger, with a narrow strip of Central Africa, passing eastwards to the alluvial regions of the Upper Nile. Even within this area, the true Negro type of conformation, such as we see in the races which inhabit the low countries near the Slave Coast—consisting in the combination of the prognathous form of skull with receding forehead and depressed nose, thick lips, black woolly hair, jet-black unctuous skin, and crooked legs—is by no means universally prevalent; for many of the nations which inhabit it must be ranked as *sub-typical* Negroes; and from these the gradation in physical characters is by no means abrupt, to those African nations which possess, in a considerable degree, the attributes which we are accustomed to exclude

* For many interesting particulars respecting the physical characters and habits of the wild tribes of the Veddahs of Ceylon, see a Paper by J. Bailey in the "Transactions of the Ethnological Society," vol. ii. p. 278.

altogether from our idea of the African race. Thus, the race of Jolofs near the Senegal, and the Guber in the anterior of Sudan, have woolly hair and deep-black complexions, but fine forms and regular features of a European cast; and nearly the same may be said of the darkest of the Kaffres of Southern Africa. The Bechuana Kaffres present a still nearer approach to the European type; the complexion being of a light-brown, the hair often not woolly but merely curled, or even in long-flowing ringlets, and the figure and features having much of the European character.—There is no group, in fact, which presents a more constant correspondence between external conditions and physical conformation, than that composed of the African nations. As we find the complexion becoming gradually darker, in passing from Northern to Southern Europe, thence to North Africa, thence to the borders of the Great Desert, and thence to the intertropical region where alone the dullest black is to be met with—so do we find, on passing southwards from this, that the hue becomes gradually lighter in proportion as we proceed farther from the equator, until we meet with races of comparatively fair complexions among the nations of Southern Africa. Even in the intertropical region, high elevations of the surface have the same effect as we have seen them to produce elsewhere, in lightening the complexion. Thus, the high parts of Senegambia, where the temperature is moderate and even cool at times, are inhabited by Fulahs of a light copper colour, whilst the nations inhabiting the lower regions around them are of true Negro blackness: and nearly on the same parallel, but at the opposite side of Africa, are the high plains of Enarea and Kaffa, of which the inhabitants are said to be fairer than the natives of Southern Europe.

810. The languages of the Negro nations, so far as they are known, appear to belong to one group, for although there is a considerable diversity in their vocabularies (arising in great part from the want of written records which would give fixity to their tongues), yet they seem to present the same grade of development and the same grammatical forms; and various proofs of their affinity with the Semitic languages have been developed, these being afforded by similarity alike of roots and of grammatical construction. The Semitic affinity of the Negro nations is farther indicated in a very remarkable manner, by the existence of a variety of superstitions and usages among the Negroes of the Western Coast, closely resembling those which prevail also among the Nilotic races whose Semitic relations are most clear, as well as among branches of the Semitic stock itself; and thus we seem to have adequate proof of the absence of any definite line of demarcation, in regard either to *physiological* or to *linguistic* characters between the Negro race, and one of those which has been hitherto considered to rank among the most elevated forms of the Caucasian variety.—Nor is there anything in the *psychical* character of the Negro which gives us a right to separate him from other races of mankind. It is true that those races which have the Negro character in an exaggerated degree are uniformly in the lowest stage of society, being either ferocious savages, or stupid, sensual, and indolent; such are most of the tribes along the Slave Coast. But, on the other hand, there are many Negro States, the inhabitants of which have attained a considerable degree of improvement in their social condition; such are the Ashanti, the Sulima, and the Dahomans of Western Africa, also the Guber of Central Sudan, among which a considerable degree of civilization has long existed; the physical characters of all these nations deviate considerably from the strongly-marked or exaggerated type of the Negro; and the last are perhaps the finest race of genuine Negroes on the whole continent, and present in their language the most distinct traces of

original relationship to the Syro-Arabian nations. The highest civilization, and the greatest improvement in physical characters, are to be found in those African nations which have adopted the Mahommedan religion; this was introduced, three or four centuries since, into the eastern portion of Central Africa; and it appears that the same people, which were then existing in the savage condition still exhibited by the Pagan nations farther south, have now adopted many of the arts and institutions of civilized society, subjecting themselves to governments, practising agriculture, and dwelling in towns of considerable extent, many of which contain 10,000, and some even 30,000 inhabitants; a circumstance which implies a considerable advancement in industry, and in the resources of subsistence. This last fact affords most striking evidence of the *improvability* of the Negro races; and, taken in connection with the many instances that have presented themselves, of the advance of individuals, under favourable circumstances, to at least the average degree of mental development among the European nations, it affords clear proof that the line of demarcation, which has been supposed to separate them intellectually and morally from the races that have attained the greatest elevation, has no more *real* existence than that which has been supposed to be justified by a difference in physical characters, and of which the fallacy has been previously demonstrated (§ 802).

811. The southern portion of the African continent is inhabited by a group of nations, which (as already mentioned) recede more or less decidedly from the Negro type in physical characters, and which seem connected together by essential community of language, as branches of the stock of which the *Kaffres* may be considered the stem. In this warlike nomadic people, which inhabit the eastern parts of South Africa, to the northward of the Hottentot country, so great a departure from the ordinary Negro type presents itself, that many travellers have assigned to them a different origin. The degree of this departure, however, varies greatly in the different Kaffre tribes; for whilst some of them are black, woolly-headed, and decidedly prognathous, so as obviously to approach the modified Negroes of Congo in general aspect, others recede considerably from the typical prognathous races, both in complexion, features, and form of head, presenting a light-brown colour, a high forehead, a prominent nose, and a tall, robust, well-shaped figure. The thick lips and black frizzled hair, however, are generally retained; though the hair is sometimes of a reddish colour, and becomes flowing; and the features may present a European cast. But even among the tribes which depart most widely from the Negro type, individuals are found who present a return to it; and it is interesting to remark, that the people of Delagoa Bay, though of the Kaffre race (as indicated by their language), having been degraded by subjugation, approach the people of the Guinea Coast in their physical characters. In fact, between the most elevated Kaffre and the most degraded Negro every possible gradation of physical and psychical characters is presented to us, as we pass northward and westwards from Kaffraria towards the Guinea Coast; and we meet with a similar transition, although not carried to so great an extent, as we pass up the eastern coast.—The languages of the Kaffres and other allied tribes are distinguished by a set of remarkable characters, which have been considered as isolating them from other African tongues. According to Dr. Latham, however, these peculiarities are not so far without precedent elsewhere as to establish the very decided line of demarcation which some have attempted to draw; and may be regarded, in fact, as resulting from the fuller development of tendencies which manifest themselves in other African languages.

812. The *Hottentot* race differs from all other South African nations both in language and in physical conformation. Its language cannot be shown to possess distinct affinities with any other stock;* but in bodily structure there is a remarkable admixture of the characters of the Mongolian with those of the Negro. Thus, the face presents the very wide and high cheek-bones, with the oblique eyes and flat nose of the Northern Asiatics; at the same time that, in the somewhat prominent muzzle and thick lips, it resembles the countenance of the Negro. The complexion is of a tawny buff or fawn colour, like the black of the Negroes diluted with the olive of the Mongols. The hair is woolly, like that of the Negroes, but it grows in small tufts scattered over the surface of the scalp (like a scrubbing-brush), instead of covering it uniformly: thus resembling in its comparative scantiness that of the Northern Asiatics. It is most interesting to observe this remarkable resemblance in physical characters, between the Hottentots and the Mongolian races, in connection with the similarity that exists between the circumstances under which they respectively live; and it is not a little curious that the Hottentot, as the Mongol, should be distinguished by the extraordinary acuteness of his vision. No two countries can be more similar than the vast steppes of Central Asia and the karroos of Southern Africa; and the proper inhabitants of each are nomadic races, wandering through deserts remarkable for the wide expansion of their surface, their scanty herbage, and the dryness of their atmosphere, and feeding upon the milk and flesh of their horses and cattle. Of the original pastoral Hottentots, however, comparatively few now remain. A large proportion of them have been gradually driven, by the encroachments of the Kaffres and of European colonists, and by internal wars with each other, to seek refuge among the inaccessible rocks and deserts of the interior; and have thus been converted from a mild, unenterprising race of shepherds, into wandering hordes of fierce, suspicious, and vindictive savages, treated as wild beasts by their fellow-men, until they become really assimilated to wild beasts in their habits and dispositions. Hence have arisen the tribes of *Bushmen* or *Bosjesmen*, which are generally regarded as presenting the most degraded and miserable condition of which the Human race is capable, and have been supposed (but erroneously) to present resemblances in physical characters to the higher Quadrumana. This transformation has taken place, under the observation of eye-witnesses, in the Koranas, a tribe of Hottentots well-known to have been previously the most advanced in all the improvements which belong to pastoral life; for having been plundered by their neighbours, and driven out into the wilderness to subsist upon wild fruits, they have adopted the habits of the Bushmen, and have become assimilated in every essential particular to that miserable tribe.—It appears, however, from the inquiries of Dr. Andrew Smith, that this process of degradation has been in operation quite independently of external agencies; nearly all the South African tribes who have made any advances in civilization being surrounded by more barbarous hordes, whose abodes are in the wilderness of

* It is considered by some, that the Hottentot language is a degraded Kaffre, as the Bushman language is a degraded Hottentot; but the Author is informed by Mr. Norris that he sees no valid ground for this assumption; the affinities of the Hottentot language being rather, in his opinion, with the languages of High Asia, although the connecting links are extremely slight. Such as they are, however, they tend to confirm an idea suggested to the Author some years since by the marked reproduction of so many Mongolian characters in the Hottentot race—that it is the remnant of a migration from Asia, earlier than that in which the great bulk of the African nations have their origin; and that it has been driven down to the remotest corner of the Continent, just as the aboriginal (Mongolian) population of south-western Europe seems to have been driven back by the Indo-European immigration (§ 805).

mountains and forests, and who constantly recruit their numbers by such fugitives as crime and destitution may have driven from their own more honest and more thriving communities; and these people vary their mode of speech designedly, and even adopt new words, in order to make their meaning unintelligible to all but the members of their association. This has its complete parallel in the very midst of our own or any other highly civilized community; all our large towns containing spots nearly as inaccessible to those unacquainted with them, as are the rude caves or clefts of hills, or the burrows scooped out of the level karroo, in which the wretched Bushman lies in wait for his prey; and these being tenanted by a people that have been well characterized as *les classes dangereuses*, which, as often as the arm of the law is paralyzed, issue forth from the unknown deserts within which they lurk, and rival in their fierce indulgence of the most degrading passions, and in their excesses of wanton cruelty, the most terrible exhibitions of barbarian inhumanity. Such outcasts, in all nations, purposely adopt, like the Bushmen, a 'flash' language; and in their general character and usages there is a most striking parallel.*

813. The *American* nations, taken collectively, form a group which appears to have existed as a separate family of nations from a very early period in the world's history. They do not form, however, so distinct a variety, in regard to physical characters, as some anatomists have endeavoured to prove; for, although certain peculiarities have been stated to exist in the skulls of the aboriginal Americans, yet it is found, on a more extensive examination, that these peculiarities are very limited in their extent—the several nations spread over this vast continent differing from each other in physical peculiarities as much as they do from those of the Old World, so that no typical form can be made out among them. In regard to complexion, again, it may be remarked, that although the native Americans have been commonly characterized as "red men," they are by no means invariably of a red or coppery hue, some being as fair as many European nations, others being yellow or brown, and others nearly, if not quite, as black as the Negroes of Africa; whilst, on the other hand, there are tribes equally red, and perhaps more deserving that epithet, in Africa and Polynesia. Our ordinary notion of the American races, having been chiefly founded upon the characters of those tribes of 'Indians' with whom European settlers first came into contact, proves to be no more applicable to the inhabitants of the Continent generally, than are the characters of the Negro to the population of Africa as a whole (§ 809).—In spite of all this diversity of conformation, it is believed that the structure of their languages affords a decided and clearly-marked evidence of relationship between them (§ 805). Notwithstanding their diversities in mode of life, too, there are peculiarities of mental character, as well as a number of ideas and customs derived from tradition, which seem to be common to them all; and which for the most part indicate a former elevation in the scale of civilization, that has left its traces among them even in their present depressed condition, and still distinguishes them from the sensual, volatile, and almost animalized savages that are to be met with in many parts of the Old Continent. —The Esquimaux have been regarded as constituting an exception to all general accounts of the physical characters of the American nations; for in the configuration of their skulls, as also in their complexion and general physiognomy, they conform to the Mongolian type, even presenting it in an exaggerated degree; whilst their wide extension along the whole northern coast of America, through the Aleutian Islands, and even to the Continent of

* See "London Labour and the London Poor," p. 2.

Asia, certainly lends weight to the idea that they derive their origin from the Northern Asiatic stock. But the increased acquaintance which has been recently gained with the tribes that people the north-eastern portion of the American Continent, has clearly shown that no physical separation can be established between the Esquimaux and the Indian proper; the one form graduating so insensibly into the other, as to make the distinction between the two groups there as difficult as on the western side it is easy. Hence the existence of the Esquimaux population in this situation affords a complete link of transition between the Asiatic and the American nations, in the precise region in which the geographical relations of the two continents would lead us to expect it.

814. It now remains for us to notice the *Oceanic* races which inhabit the vast series of islands scattered through the great ocean that stretches from Madagascar to Easter Island. There is no part of the world which affords a greater variety of local conditions than this, or which more evidently exhibits the effects of physical agencies on the organization of the human body. Moreover, it affords a case for the recognition of affinities by means of language that possesses unusual stability; since the insulated position of the various tribes that people the remote spots of this extensive tract prevents them from exercising that influence upon each other's forms of speech which is to be observed in the case of nations united by local proximity or by frequent intercourse. Tried by this test, it is found that the different groups of people inhabiting the greater part of these insular regions, although so widely scattered and so diverse in physical characters, are more nearly connected together than most of the families of men occupying continuous tracts of land on the great continents of the globe. A probable explanation of this remarkable affinity has been afforded by the careful investigation of the Flora and Fauna of those regions* by Sir Joseph Hooker and Mr. Wallace; whose observations furnish strong evidence that most important and extensive geological changes have taken place since the islands scattered over that region have been peopled by their existing inhabitants. The western and eastern halves of the Indian archipelago, the former containing Sumatra and Borneo, the latter including Celebes and New Guinea, are separated at their nearest approximation by the Straits of Lombok, which are no more than fifteen miles wide: the Fauna of the former is essentially Asiatic, that of the latter essentially Australian; and there is no other intermixture between them than such as a very limited migration across this narrow channel will readily account for. Now the various portions of the Indian province are still connected by a vast submarine plain, which extends over the whole of the Java Sea, the Straits of Malacca, the Gulf of Siam, and the southern part of the China Sea, at a depth of not more than three hundred feet, abruptly terminating at its limits in an unfathomable ocean. An elevation of the sea-bottom to this amount, therefore, would nearly double the extent of tropical Asia; and there is every probability that the Continent *was* thus extended before that last great elevation of the volcanic range of Java and Sumatra took place, which (according to the general fact first brought into notice by Dr. Darwin, of an alternation of bands of elevation and depression) was coincident with the subsidence that separated those islands from Borneo on the one side and

* See the "Introductory Essay to the Flora of New Zealand," by Sir J. D. Hooker, 1853, and his "Flora of Australia; its Origin, Affinities, and Distribution," 1859. Also Mr. A. R. Wallace, 'On the Zoological Geography of the Malay Archipelago,' in the "Proceedings of the Linnæan Society" for November, 1859; and the Review of these works in the "Medico-Chir. Rev." for 1860, vol. xxv. p. 371, as well as his more recent work on "Geographical Distribution."

from the continent of Asia on the other. On the other hand, the great Pacific Continent, of which New Guinea and Australia are doubtless fragments, and which (as Sir Joseph Hooker has rendered probable by botanical and Wallace* by zoological considerations) once connected Australia and New Zealand with South America, seems to have extended itself as far westward as the Moluccas; and *its* submergence, producing the limitation and separation of the great islands of the South Sea, seems to have taken place before the rise of the tropical Asiatic continent. There are even indications that the tropical Indian Continent extended so near to what is now the coast of Africa, that the Isle of Bourbon and the Mauritius, perhaps even Madagascar, were outlying portions of it; and if the submergence which formed the bed of the present Indian Ocean should have taken place subsequently to the time when those countries became inhabited by Man, we have a rational explanation of the fact which has perplexed all ethnologists, and which the hypothesis of migration can scarcely be stretched far enough to account for—that both the Fauna and the languages of Madagascar are rather Malayo-Polynesian than African in their fundamental affinities.

815. The inhabitants of Oceania seem divisible into two principal groups, which are probably to be regarded as having constituted distinct races from a very early period; these are, the Malayo-Polynesian race, and the Negritos or Pelagian Negroes. The *Malayo-Polynesian* group is by far the more extensive of the two; and comprehends the inhabitants of the greater part of the Indian and Polynesian Archipelagoes, with the peninsula of Malacca (which is the centre of the Malays proper), and perhaps the inhabitants of Madagascar. These are all closely united by affinities of language. The proper Malays bear a strong general resemblance to the Mongolian races, and this resemblance is shared, in a greater or less degree, by most of the inhabitants of the Indian Archipelago. They are of a darker complexion, as might be expected from their proximity to the equator; but in this complexion yellow is still a large ingredient. The Polynesian branch of the group presents a much wider diversity; and if it were not for the community of language, it might be thought to consist of several races as distinct from each other as from the Malayan branch. Thus the Tahitians and Marquesans are tall and well-made; their figures combine grace and vigour; their skulls are usually remarkably symmetrical; and their physiognomy presents much of the European cast, with a very slight admixture of the features of the Negro. The complexion, especially in the females of the higher classes who are sheltered from the wind and sun, is of a clear olive or brunette, such as is common among the natives of Central and Southern Europe; and the hair, though generally black, is sometimes brown or auburn, or even red or flaxen. Among other tribes, as the New Zealanders and the Tonga and Friendly Islanders, there are greater diversities of conformation and hue; some being finely proportioned and vigorous, others comparatively small and feeble; some being of a copper-brown colour, others nearly black, and others again almost white. In fact, if we once admit a strongly-marked difference in complexion, features, hair, and general configuration, as establishing a claim to original distinctness of origin, we must admit the application of this hypothesis to almost every group of islands in the Pacific—an idea, of which the essential community of language seems to afford a sufficient refutation. Among the inhabitants of Madagascar, too, all of which speak dialects of the same language, some bear a strong resemblance to those of the Malayan type, whilst others present approaches to that of the Negro.

* A. R. Wallace, "Geographical Distribution of Animals," vol. i. 1876, p. 387.

816. The *Negrito* or *Pelagian-Negro* races must be regarded as a group altogether distinct from the preceding; having a marked diversity of language; and presenting, more decidedly than any of the Malayo-Polynesians, the characters of the Negro type. They form the predominating population of New Britain, New Ireland, the Louisiade and Solomon Isles, of several of the New Hebrides, and of New Caledonia; and they seem to extend westwards into the mountainous interior of the Malayan Peninsula, and into the Andaman Islands in the Bay of Bengal.* The Tasmanians, or aborigines of Van Diemen's Land, who are now almost completely exterminated, undoubtedly belonged to this group. Very little is known of them, except through the reports of the people of Malayo-Polynesian race inhabiting the same islands; but it appears that, generally speaking, they have a very inferior physical development, and lead a savage and degraded life. There is considerable diversity of physical characters among them; some approximating closely in hair, complexion, and features, to the Guinea-Coast Negroes; whilst others are of yellower tint, straight hair, and better general development. The *Papuans*, who inhabit the northern coast of New Guinea and some adjacent islands, and who are remarkable for their large bushy masses of half-woolly hair, have been supposed to constitute a distinct race; but there is little doubt that they are of hybrid descent, between the Malays and the Pelagian Negroes.—To this group we are probably to refer the *Alfourous* or *Alforian* race, which are considered by some to be the earliest inhabitants of the greater part of the Malayan Archipelago, and to have been supplanted by the more powerful people of the preceding races, who have either extirpated them altogether, or have driven them from the coasts into the mountainous and desert parts of the interior. They are yet to be found in the central parts of the Moluccas and Philippines; and they seem to occupy most of the interior and southern portion of New Guinea, where they are termed Endamenes. They are of very dark complexion; but their hair, though black and thick, is lank. They have a peculiarly repulsive physiognomy; the nose is flattened, so as to give the nostrils an almost transverse position; the cheek-bones project; the eyes are large, the teeth prominent, the lips thick, and the mouth wide. The limbs are long, slender, and misshapen. From the close resemblance in physical characters between the Endamenes of New Guinea and the aborigines of New Holland, and from the proximity between the adjacent coasts of these two islands, it may be surmised that the latter belong to the Alforian race; but too little is known of the language of either to give this inference a sufficient stability. In the degradation of their condition and manner of life, the savages of New Holland fully equal the Bushmen of South Africa; and it is scarcely possible to imagine human beings existing in a condition more nearly resembling that of brutes. But there is reason to believe, that the tribes in closest contact with European settlers are more miserable and savage than those of the interior; and even with respect to these, increasing acquaintance with their language, and a consequent improved insight into their modes

* An interesting paper 'On the Mincopie Race of the Andaman Isles,' by Professor Owen, will be found in the "Transactions of the Ethnological Society" for 1863, p. 34. They appear to be amongst the most degraded of the Human species, possessing no notion of a Supreme Being, nor of a future existence, nor any sense of decency or shame; they are of diminutive size, yet the cranium is well formed, of an oval type, with rather receding forehead, and they are skilful in making knives of glass and iron cast up from wrecks. They possess considerable powers of imitation, and are active in running, climbing, and swimming. They are not cannibals. Prof. Owen concludes that they are the aborigines of these islands, but remarks that antecedent generations may have coexisted with the slow and gradual geological changes which have obliterated the place or continent of their primitive origin. See also a Paper on 'The Admiralty Islanders,' by H. N. Moseley, "Trans. Anthrop. Soc.," 1877.

of thought, tend to raise the very low estimate which has been formed and long maintained in regard to their extreme mental degradation. The latest and most authentic statements enable us to recognize among them the same principles of a moral and intellectual nature, which, in more cultivated tribes, constitute the highest endowments of humanity; and thus to show that they are not separated by any impassable barrier from the most civilized and elevated nations of the globe.—There are many indications, indeed, that the Negrito race is not so radically distinct from the Malayo-Polynesian as the marked physical dissimilarity of their respective types, and the apparent want of conformity between their languages, would make it appear. For as, on the one hand, some of the subdivisions of the latter present a decided tendency towards that prognathous character and depth of complexion which are typical of the former, so among the former do we not unfrequently meet with a lighter shade of skin, a greater symmetry of skull, and a considerable improvement in form and feature. And although no very close relationship can be discovered between the Negrito and Malayo-Polynesian languages, yet it has been pointed out by Mr. Norris that a much more decided relationship exists between the Australian and the Tamulian (§ 808); and remote as this connection seems, the circumstance adds weight to the idea, that the native Australians (with other Negrito tribes) are an off-set from that southern branch of the great nomadic stock of Central Asia, which seems early to have spread itself through the Indo-Chinese and the Indian Peninsulas, and to have even there shown an approximation to the prognathous type.

817. Looking, then, to the great diversity which exists among the subordinate groups of which both these divisions consist, and their tendency to mutual approximation, it cannot be shown that any sufficient reason exists for isolating them from each other; and, as already remarked (§ 815), there seems no medium between the supposition that each island had its aboriginal pair or pairs, and the doctrine that the whole of Oceania has been peopled from a common stock. Looking, again, to the very decided approximation which is presented by certain Oceanic tribes to the Mongolian type, and this in localities which, on other grounds, might be regarded as having received the first stream of migration, the possibility, to say the least, can scarcely be denied, that the mainland furnished the original stock, which has undergone various transformations subsequently to its first dispersion; these having been the result of climatic influence and mode of life, and having been chiefly influenced as to degree by the length of time during which the transforming causes have been in operation. At any rate, it may be safely affirmed, that the Oceanic races are not entitled by any distinctive physical peculiarity to rank as a group which must have necessarily had an original stock distinct from that of the Continental nations.

CHAPTER XX.

OF THE MODES OF VITAL ACTIVITY CHARACTERISTIC OF DIFFERENT AGES.

818. Although from the time when the Human being comes into the world, to the final cessation of his corporeal existence, the various functional operations of Organic life are carried on with ceaseless activity, whilst those of Animal life are only suspended by the intervals of repose which are needed for the renovation of their organs, yet there are very marked differences, not

only in the *degree of their united activity*, but also in the *relative degrees of energy which they severally manifest*, at different epochs. These differences, taken in connection with the modifications in the size and conformation of the body with which they are in relation, mark out the whole term of life into the various 'Ages,' which are commonly recognized as seven—namely, Infancy, Childhood, Youth, Adolescence, Manhood, Decline, and Senility. For Physiological purposes, however, a less minute subdivision is equally or perhaps more appropriate—namely, the three great periods of *Growth and Development*, of *Maturity*, and of *Decline*. The first comprehends the whole of that series of operations by which the germ evolves itself at the expense of the nutriment which it appropriates from external sources into the complete organism, possessed not merely of its full dimensions, but of its highest capacity for every kind of functional activity; this includes, therefore, the epochs of Embryonic life, Infancy, Childhood, Youth, and Adolescence, all of which are characterized by an *excess* of the *constructive* over the *destructive* changes taking place in the organism. The second period ranges over the whole term of Manhood, in which the organism, having attained its complete development, is brought into vigorous and sustained activity; and in which it is *maintained* in a condition fitted for such activity, by the equilibrium which subsists between the operations of redintegration and of disintegration. The third period commences with the incipient failure of the bodily powers, consequent upon the *diminished* activity of the *constructive* powers, as compared with that of the changes which involve *degeneration* and *decay;* this diminution begins to manifest itself during the latter part of Middle Life, before Old Age can properly be said to commence; and it continues in an increasing ratio through the whole 'decline of life,' until the reparative powers being exhausted, Death supervenes as the necessary termination of that long succession of phenomena of which Life consists.

819. Although the organization of the body at each epoch may be truly said to be the *resultant* of all the *material* changes which it has undergone during the preceding periods, yet it is scarcely possible to take an enlarged view of the case, without perceiving that we must look for the cause of this succession in those *dynamical* conditions, the presence of which is the distinguishing attribute of living structures. Every *constructive* act, whether this consist in Growth (§ 309) or in Development (§ 310), not merely requires *materials* for the new tissue produced, but depends upon the active operation of a *formative power*, without whose agency these materials would remain unorganized. In our examination into the source of the formative power which we see thus operating in every individual organism (CHAP. I.), we found it traceable to the *Physical* Forces to which it is subjected (Heat being the one which seems to bear most directly upon the formative operations); these forces being metamorphosed, so to speak, into the constructive force of the living body, in virtue of the peculiar endowments of *its* material substratum—just as an Electric current transmitted through the different nerves of Sense produces the sensory impressions which are characteristic of each respectively (§ 426); or as the same current, transmitted through one form of Inorganic matter, produces Light and Heat, through another, Chemical Change, or through another, Magnetism. But we must also recognize in the Organism at large, as well as in every integral part of it, a certain *capacity* for growth and development—which is the original endowment of its *germ*—which not only determines the mode in which it shall progressively evolve itself into the fabric characteristic of its species and sex, but also shapes the peculiarities of the individual—which serves also to bring about the per-

petual reconstruction that is needed for its continued maintenance, and is peculiarly manifested in those reparative processes which make good losses of its substance resulting from injury or disease—and of which the cessation, by preventing any further metamorphoses of Physical into Vital force, causes the constructive powers to fail altogether, so that the Organism is resolved back by these very forces into the various forms of Inorganic matter at the expense of which it had been built up.

820. Now this 'general capacity' is most strikingly displayed during those earliest periods of existence, in which growth and development alike are taking place most rapidly; in fact, the farther we go back in the history of intra-uterine life, the more energetic do we perceive its manifestations to be. For when we look simply at the *increase* from the minute point that constitutes the first perceptible germ, to the mature fœtus of 6 or 7 lbs. weight, we see that at no other period of existence can that increase be compared in its rate with that which presents itself during the nine months that follow conception; and if we go more into detail, we find that it is yet more remarkable in the earlier than in the later months (§ 822). So, again, it is in the first few weeks of embryonic life that the foundation is laid of most of its permanent *organs*, in the midst of an apparently homogeneous mass of cells; whilst in the succeeding weeks these rudiments are evolved into the semblance of the forms they are subsequently to present, and a differentiation of *tissues* begins to show itself in their several parts; so that the developmental process is so far advanced at little more than half the term of gestation, that the fœtus may even then, under favourable circumstances, maintain an independent existence (§ 722). The rate of increase becomes progressively slower during the advance from infancy to maturity; and the energy of the developmental process is comparatively enfeebled, being limited to the perfecting of structures whose foundations had been previously laid, and in no instance manifesting itself normally in the evolution of a new part or organ. Now as there is no limit (in the well-nourished individual) to the supply of Food and Warmth, it follows that this gradual decline of formative activity must be due to a diminution of the *capacity* for that activity, inherent in the organism itself; and this diminution is still more strongly marked by that entire cessation, both of increase, and of further developmental changes, which constitutes the termination of the first period. For the organism which has attained that stage of its existence has so far lost the formative capacity which characterized its earlier years, that, however copious the supply of food, however abundant the generation of heat, it can thenceforth do no more than *maintain* its normal condition, and can effect this for only a limited term of years. It seems a necessary sequence of this series of phenomena, that the time should come, when, after a period of gradual decline, the germinal capacity of the organism should be so much reduced as no longer to suffice for the maintenance of its own integrity; and whenever such is the case, the termination of its existence as a living body must be the necessary result. Hence we find that there is a natural limit, not only to the size and development of the organism, but also to the duration of its life. And although that limit in each case is subject to variation amongst *individuals*, partly in consequence of diversity of external conditions, but partly (it may be surmised) through differences in the measure of germinal capacity possessed by each, yet there is a limit also to these variations, so that the character of the *species* is never departed from.

821. *Period of Growth and Development.*—The general history of the first part of this period, that of Embryonic existence, has already been so fully given, that it is only necessary here to remark briefly in regard to the charac-

ter of its vital operations, that the whole nisus of its activity is directed rather to the performance of the *vegetative* or *organic* than to that of the *animal* functions; the action of the heart, and the occasional reflex movements of the limbs, being its only manifestations of nervo-muscular power. And thus it seems to be that the formative capacity is greater during embryonic life, than at any subsequent period, and greater in its earlier than its later stages; so that we have not only evidence of an extraordinary power of regenerating parts which have been lost by disease or accident, as seen in attempts at the reproduction of entire limbs after their 'spontaneous amputation' (§ 337); but there is also not unfrequently an absolute excess of productive power, as shown in the development of supernumerary organs, which may even proceed to the extent of the complete duplication of the entire body, by the early subdivision of the embryonic structure into two independent halves.—It is to be noticed, also, that the embryo derives its supply not merely of food, but also of *heat*, from its maternal parent; and it is probably owing especially to the constancy with which this force operates, that the period of embryonic development is so uniform in Man (as in warm-blooded Animals generally), by comparison with the corresponding developmental periods in Plants and cold-blooded Animals, these being entirely determined by the degree of heat to which the embryos are subjected.

822. It is frequently of great importance, both to the Practitioner and to to the Medical Jurist, to be able to determine the *age* of a Fœtus from the physical characters which it presents; and the following Table has been framed by Devergie* in order to facilitate such determination. It is to be remarked, however, that the *absolute length* and *weight* of the Embryo are much less safe criteria than its *degree of development*, as indicated by the relative evolution of the several parts which make their appearance successively. Thus it is very possible for one child born at the full time, to *weigh* less than another born at 8 or even at 7 months; its *length*, too, may be inferior; and even the position of the *middle point* of the body is not, taken alone, a safe criterion, since it is liable to variation in individuals.†

Embryo 3 *to* 4 *weeks*.—It has the form of a serpent;—its length from 3 to 5 lines;—its head indicated by a swelling;—its caudal extremity (in which is seen a white line, indicating the continuation of the medulla spinalis), slender, and terminating in the umbilical cord;—the mouth indicated by a cleft, the eyes by two black points;—members begin to appear as nipple-like protuberances;—liver occupies the whole abdomen;—the bladder is very large;—the chorion is villous, but its villosities are still diffused over the whole surface.

Embryo of 6 *weeks*.—Its length from 7 to 10 lines;—its weight from 40 to 75 grains;—face distinct from cranium;—aperture of nose, mouth, eyes and ears perceptible;—head distinct from thorax;—hands and fore-arms in the middle of the length; fingers distinct;—legs and feet situated near the anus;—clavicle and maxillary bone present a point of ossification;—distinct umbilicus for attachment of cord, which at that time consists of the omphalo-mesaraic vessels, of a portion of the urachus, of a part of the intestinal tube, and of filaments which represent the umbilical vessels;—the placenta begins to be formed; the chorion still separated from the amnion;—the umbilical vesicle very large.

Embryo of 2 *months*.—Length from 16 to 19 lines; weight from 150 to 300 grains;—elbows and arms detached from the trunk;—heels and knees also isolated;—rudiments of the nose and of the lips;—palpebral circle beginning to show itself;—clitoris or penis apparent;—anus marked by a dark spot;—rudiments of lungs, spleen, and suprarenal capsules;—cæcum placed behind the umbilicus;—digestive canal withdrawn into the abdomen;—urachus visible;—osseous points in the frontal bone and in the ribs;—chorion commencing to touch the amnion at the point opposite the insertion of the placenta;—placenta begins to assume its regular form;—umbilical vessels commence twisting.

---

* "Médecine Légale," 3ème édit.; tom. i. p. 279.

† See, on this last point, Moreau in "Lancette Française," 1837; and Dr. A. Taylor in "Guy's Hospital Reports," 1842.

Embryo of 3 months.—Length from 2 to 2½ inches;—weight from 1 oz. to 1½ oz. (Troy)—head voluminous:—eyelids in contact by their free margin;—membrana pupillaris visible;—mouth closed;—fingers completely separated;—inferior extremities of greater length than rudimentary tail;—clitoris and penis very long;—thymus as well as suprarenal capsules present;—cæcum placed below the umbilicus;—cerebrum 5 lines, cerebellum 4 lines;—medulla oblongata 1½ line, and medulla spinalis ¾ of a line in diameter;—two ventricles of heart distinct;—the decidua reflexa and decidua uterina in contact;—funis contains umbilical vessels and a little of the gelatin of Wharton;—placenta completely isolated;—umbilical vesicle, allantois, and omphalo-mesaraic vessels have disappeared.

Fœtus of 4 months.—Length 5 to 6 inches;—weight 2½ to 3 oz.; skin rosy, tolerably dense;—mouth very large and open;—membrana pupillaris very evident;—nails begin to appear;—genital organs and sex distinct;—cæcum placed near the right kidney;—gall-bladder appearing;—meconium in duodenum;—cæcal valve visible;—umbilicus placed near pubis;—ossicula auditûs ossified;—points of ossification in superior part of sacrum;—membrane forming at point of insertion of placenta on uterus;—complete contact of chorion with amnion.

Fœtus of 5 months.—Length 6 to 7 inches;—weight 5 to 7 oz.;—volume of head still comparatively great;—nails very distinct;—hair beginning to appear;—skin without sebaceous covering;—white substance in cerebellum;—heart and kidneys very voluminous;—cœcum situated at inferior part of right kidney;—gall-bladder distinct;—germs of permanent teeth appear;—points of ossification in pubis and calcaneum;—meconium has a yellowish green tint, and occupies commencement of large intestine.

Fœtus of 6 months.—Length 9 to 10 inches;—weight 1 lb.;—skin presents some appearance of fibrous structure;—eyelids still agglutinated, and membrana pupillaris remains;—sacculi begin to appear in colon;—funis inserted a little above pubis;—face of a purplish red;—hair white or silvery;—sebaceous covering begins to present itself;—meconium in large intestine;—liver dark-red; gall-bladder contains serous fluid destitute of bitterness;—testes near kidneys;—points of ossification in four divisions of sternum;—middle point at lower end of sternum.

Fœtus of 7 months.—Length 13 to 15 inches;—weight 3 to 4 lbs.;—skin of rosy hue, thick, and fibrous;—sebaceous covering begins to appear;—nails do not yet reach extremities of fingers;—eyelids no longer adherent;—membrana pupillaris disappearing;—a point of ossification in the astragalus;—meconium occupies nearly the whole of the large intestine;—valvulæ conniventes begin to appear;—cæcum placed in right iliac fossa;—left lobe of liver almost as large as right;—gall-bladder contains bile;—brain posssesses more consistency;—testicles more distinct from kidneys;—middle point at a little below end of sternum.

Fœtus of 8 months.—Length 14 to 16 inches;—weight 4 or 5 lbs.;—skin covered with well-marked sebaceous envelope;—nails reach extremities of fingers;—membrana pupillaris becomes invisible during this month;—a point of ossification in the last vertebra of sacrum;—cartilage of inferior extremity of femur presents no centre of ossification;—brain has some indications of convolutions;—testicles descend into inguinal ring;—middle point nearer the umbilicus than the sternum.

Fœtus of 9 months, the full term.—Length from 17 to 21 inches;—weight from 5 to 9 lbs., the average probably about 6½ lbs;—head covered with hair in greater or less quantity, of from 9 to 12 lines in length;—skin covered with sebaceous matter, especially at bends of joints;—membrana pupillaris no longer exists;—external auditory meatus still cartilaginous;—four portions of occipital bone remain distinct;—os hyoides not yet ossified;—point of ossification in the centre of cartilage at lower extremity of femur;—white and grey substances of brain become distinct;—liver descends to umbilicus;—testes have passed inguinal ring, and are frequently found in the scrotum;—meconium at termination of large intestine;—middle point of body at umbilicus, or a little below it.

823. From the time of its entrance into the world, the condition of the Human infant is essentially changed. It is no longer supplied with nutriment by the direct transmission of organizable materials from the circulating fluid of the mother to its own; but obtains it by the processes of digestion, absorption, and assimilation, which involve the establishment of new modes of vital activity in its own organism. In order, however, that the change may not be too sudden, the nutriment provided by Nature for the early period of infantile lise, is such as to occasion the least possible demand upon its vital powers, for the preparation of the organizable material which is required for its further growth and development. But the transition is a most important one in another particular; the infant is now thrown in a great degree upon its own

resources for the generation of its Heat; the necessary combustion being promoted by the arrangements for that active Respiration, which now supersedes the very limited aëration of its circulating fluids that was sufficient during fœtal life. In the movements of the respiratory muscles and of the walls of the alimentary canal, we have a new source of expenditure of vital force, and of destruction of tissue; and this expenditure is progressively augmented, as the motions of the body and limbs become increasingly active. Thus we find that the formative powers are not exercised during Infancy and Childhood, solely in the *construction* and *augmentation* of the fabric (as they were during embryonic life), since there is a constant demand upon them for its *maintenance;* and this demand becomes greater, and greater, in proportion to the activity of the Animal powers. These, at first called into exercise by the stimulus of sensory impressions upon the Nervous system, are speedily brought into very energetic operation. This operation is of an extremely limited character, being at first purely *sensorial*, and for some time afterwards simply *perceptive*. But the *whole Mind* (such as it is) being given up to it, *habits of observation* are formed, which are never subsequently lost; the infant learns *how to use* his Organs of Sense; and he also acquires those powers of *interpreting* their indications, which become so completely engrafted into his nature, as henceforth to seem a part of it. Although this Education of the Senses will necessarily go on, even without any intentional assistance on the part of others, yet it is in the power of the Mother or Nurse to promote it effectually, by supplying objects of various kinds which the Infant may look at and grasp, and by not abruptly interfering (by the too speedy withdrawal of such objects) with the process by which the visual and tactile perceptions are blended and harmonized (§ 576).—The Nervous system of the Infant, although thus called into extraordinarily energetic activity, cannot long sustain that activity; a very large measure of Sleep is required for the restoration of its speedily exhausted powers; and any unsual excitement of them tends to injurious disturbances of its nutrition. It is owing to this peculiar susceptibility of the Nervous system of the infant to external influences, that medicines (especially narcotics) which exert a special influence upon that system, are so peculiarly potent in their effects at this period of life, that the greatest caution is needed in their administration.

824. The most important developmental change which occurs in Infancy, after the complete establishment of the extra uterine circulation (§ 741), is the completion and eruption of the first set of Teeth; the greater part of whose formation, however, has taken place before birth. These 'milk' or 'deciduous' teeth, 20 in number, usually make their appearance in the following order;—The four central Incisors first present themselves, usually about the 7th month after birth, but frequently much earlier or later; those of the lower jaw appear first. The lateral Incisors next show themselves, those of the lower jaw coming through before those of the upper; they usually make their appearance between the 7th and 10th months. After a short interval, the anterior Molars present themselves, generally soon after the termination of the 12th month; and these are followed by the Canines, which usually protrude themselves between the 14th and 20th months. The posterior Molars are the last, and the most uncertain in regard to their time of appearance; this varying from the 18th to the 36th month. In regard to all except the front teeth, there is no settled rule as to the priority of appearance of those in the upper or under jaw; sometimes one precedes, and sometimes the other; but in general it may be stated that whenever one makes its appearance, the other cannot be far off. The same holds good in regard to the two sides, in which develop-

ment does not always proceed exactly *pari passu*.—The period of Dentition is sometimes one of considerable risk to the Infant's life; and this especially when an irritable state of the nervous system has been brought about by unsuitable food, unwholesome air, or some other cause of disordered health. In such cases the pressure upon the nerves of the gum, which necessarily precedes the opening of the sac and the eruption of the tooth, is a fruitful source of irritation; producing disturbance of the whole system, and giving origin to Convulsive affections which are not unfrequently fatal. These have been particularly studied by Dr. M. Hall, who recommends the free use of the gum lancet, as a most important means of prevention and cure; but the Author has no doubt that too much attention has been given to the immediate source of the irritation, and too little to the general state of the system; and that constitutional treatment, especially change of air, and improvement of the diet, is of fundamental importance. In infants whose general health is good, and who are not over-fed, Dentition is usually a source of but very trifling disturbance; a slight febrile action, lasting only for a day or two, being all that marks the passage of the tooth through the capsule; and its eruption through the gum taking place without the least indication of suffering or disorder. Any existing malady or abnormal tendency, however, is pretty sure to be aggravated during the 'cutting of the teeth;' and it is therefore of the greatest consequence, that the infant should be withdrawn during this period from all injurious influences; and that no irregularity of diet, or deficiency of fresh air and exercise, should operate to its disadvantage.

825. Although there are no well-marked divisions between the periods of Childhood, Youth, and Adolescence, through all of which we witness the continuance of the processes of Growth and Development (though in a gradually decreasing ratio), yet we may appropriately distinguish each as the epoch of one of those important changes which tend towards the completion of the fabric—namely, *Childhood* as ranging through the greater part of the period of the second Dentition—*Youth* as characterized by that increased evolution of the sexual organs, and by those general constitutional changes accompanying that evolution, which altogether constitute Puberty,—and *Adolescence* as distinguished by that entire consolidation of the Osseous skeleton, which is not completed until the full stature has been attained. It will be convenient first to consider what is common to all these periods; and then to notice the features by which they are severally characterized.

826. The passage from Infancy to Childhood may be regarded as marked by the eruption of the 'deciduous' Teeth; by the termination of that direct supply of food to the offspring, which is afforded until then by the mammary secretion of the mother; by the dawn of the Intellectual powers, manifested in the first efforts at speaking; and by the acquirement of sufficient control over the muscular apparatus, to render it subservient to the increasing desire which then displays itself for independent Locomotion. All these advances usually take place simultaneously, or nearly so, during some part of the second year; some Infants being much more forward than others, both in 'cutting their teeth' and in learning to walk and to talk. When they have been completed, the Child enters upon a life which is in many respects new. The alteration of its diet involves a much higher activity of all the organs which are concerned in making blood; whilst its greatly increased amount of exertion, both of body and mind, gives occasion to a more rapid disintegration of the nervous and muscular tissues, and hence to a higher activity of the Excretory organs. This will, of course, progressively augment, in proportion as the Nervo-muscular apparatus is brought, with advancing years, into more

vigorous and more prolonged exercise; until, with the attainment of adult age, the disintegration of these tissues comes to be the chief source of the Excrementitious products. But during the whole period of increase there is another source of demand for nutritive activity, in that perpetual *reconstruction* of the fabric (involving a sort of continual pulling down and rebuilding on a larger scale, all the old materials being carried away as useless) which is a necessary condition of its growth: but this demand of course slackens with the diminution of the rate of increase; and at last it ceases altogether, just when the other attains its maximum. Hence the demand for food, on the one hand, and the amount of excretory matter set free from the body, on the other, are remarkably large during the whole of this period; the child, as every one knows, consuming far more nutriment than the adult, in proportion to the weight of their respective bodies; and the like being true of the quantity of carbonic acid exhaled from the lungs and of the urea given off from the kidneys.—That the germinal capacity, though inferior to that of the embryo, still persists in a high degree during the period of childhood and youth, is shown in the readiness with which the effects of injuries and disease are recovered from; for although the regeneration of lost parts does not take place to nearly the same extent as during early embryonic life, yet up to a certain point it is effected with great completeness, and with much greater rapidity than at later epochs. It is still, in fact, rather in the exercise of formative power, than in the production of nervo-muscular vigour, that the vital force of the earlier part of this period is displayed; and we may readily trace such a relation of reciprocity between these two modes of its manifestation as is strongly indicative of the community of their source. For it is familiar to every observer, that, when the growth of a child or a young person is peculiarly quick, his nervo-muscular energy is usually feeble, and his power of endurance brief, in comparison with that which can be put forth by one whose frame is undergoing less rapid increase. And we observe, moreover, that the capacity of resistance to depressing influences of various kinds, which is a no less decided manifestation of the vital power of the organism (seeing that these influences are of such a kind as to *tend towards* its death), is possessed by the latter in a far higher degree than by the former. This is remarkably the case in regard to privation of food and depression of external temperature; under which, too, children and young persons succumb much more speedily than adults.

827. It is most interesting to trace, during the progress of the development of the bodily fabric, the gradual expansion and invigoration of the Mental powers. The acquirement of Language constitutes the most important step in the development of the *ideational* consciousness; and it is easy to recognize in the psychical manifestations of Children, the further progress of that development. The formation of *Associations* between ideas takes place with extraordinary readiness and tenacity during the earliest period of childhood; and these exercise so much influence over the succession of the thoughts during the whole remainder of life, that "the force of early associations" has become proverbial. Out of these associations arise, on the one hand, Memory and Imagination; on the other hand, those simple processes of Reasoning which are necessary to the development of a higher class of ideas. Thus the mind passes from those primary notions of individual objects which are directly suggested by sense perceptions, to those *abstract* ideas of their qualities, which enable them to recognize those qualities elsewhere, notwithstanding the existence of differences in other respects; and thence to those *general* ideas, in which the abstractions are embodied. In all these processes, the child mind

seems to be so entirely concentrated upon the particular subject of its thoughts, as to be 'possessed' by it for the time, almost as completely as a 'hypnotised' subject is by his dominant idea; and no prolonged study of it is required to justify the statement, that its operations are for some time entirely *automatic*, and that the acquirement of Volitional control over them, on the part of the individual, is a very gradual process. As a general rule it may be laid down that the activity with which the formation of new ideas takes place in the child and the rapidity with which the attention transfers itself from one object to another, prevents any single state from fixing itself durably in the consciousness, so that the Memory preserves but faint traces of the greater part of what passes through the mind; and it is (for the most part) only when the same thoughts are frequently recurred to, that they take root (so to speak) in the psychical nature. Still we occasionally find that particular impressions exert a very powerful influence on the subsequent course of thought and feeling; and there is good reason to believe that even where the *consciousness* loses its hold over them, impressions of a transient nature may leave such traces in the Brain, that they may be reproduced at any future time when the appropriate suggestion may happen to be supplied.—Whilst the ideational consciousness is thus being expanded and elevated, the *Emotional* part of the Psychical nature is rapidly acquiring a greater range and intensity of action. The infant and young child give ample evidence in their actions of the several forms of Emotional Sensibility which connect themselves with Sensational and Perceptive states; but no sooner does the development of Ideas commence, than the various modifications of 'feeling' attach themselves to *these;* and thus almost every thought that is not a purely intellectual abstraction, comes to possess more or less of an Emotional character. Here, again, we trace the powerful influence of early impressions; for notwithstanding that the state of feeling which is habitual to each individual may depend in great degree upon his original constitution, yet it is unquestionable that it is largely influenced (especially in its association with particular classes of ideas) by *sympathy* with the like states in those among whom the child receives its early education. It is of peculiar importance, therefore, that this example should be such as it is wholesome for the child to imitate; since it is upon the habits of feeling thus early formed, that the happiness and right conduct of after life mainly depend. This statement (which applies with yet greater force to the Moral Sense) may at first seem inconsistent with the well-known fact that the Emotions of children are peculiarly transient in their character, even when they are violently excited; one state of feeling giving place to another, even of the most opposite kind, under the influence of some new impression or of some change in the direction of the ideas. But the same general principle applies to this case, as to the formation of habits of thought—namely, that although individual impressions are more speedily dissipated from the minds of children than from those of adults, yet that when impressions of the same kind are frequently repeated, the brain *grows to* them in such a manner that they come to take part (as it were) in its ordinary working; and thus, by establishing a particular mode of nutritive assimilation, they tend to *perpetuate* this acquired habit, of whatever nature it may be.—The right training of the Emotional tendencies and all the higher uses of the Intellectual Faculties, depend in great degree, as may readily be shown, upon the influence of the Will in directing the current of thought and feeling; and this becomes greater and greater, if rightly cultivated, with the advance of years, so that the psychical powers, whilst themselves acquiring an increase of vigour and comprehensiveness, are brought more and more under the control of the individual, and can be utilized in any

way in which he may choose to employ them. Thus, with a diminishing *mobility* of thought and *excitability* of feeling, the Mind becomes more and more capable of *sustained* and *determinately-concentrated* activity; and is at the same time progressively acquiring that store of familiar *experiences*, which not only constitutes the basis of all attainments in special departments of knowledge, but supplies (when judiciously used) that 'common sense' by which we form most of our judgments and direct most of our conduct.—During this period, moreover, the Muscular apparatus of animal life, whose actions are at first purely automatic, is brought more and more under the direction of the Mind, so as to express its ideas, its feelings, and its volitions. And it is whilst this transference is going on, that new habits of action are most readily formed, and when once formed, are durably impressed upon the organism.—The excess which must exist, during the whole of this period, in the *constructive* over the *destructive* activity, and the large amount of the latter which (as already shown) arises out of the very nature of Growth, in addition to that which proceeds from the increased activity of the Animal functions, necessitates a much larger proportion of repose than suffices for the adult; but this necessity diminishes with the progress of years, for the reasons already mentioned; and thus we find that whilst the young child passes 16 or 18 hours a day in sleep, half that time suffices for the youth just entering on manhood.

828. The *Second Dentition*, consisting in the replacement of the *deciduous* or 'milk' Teeth by the *permanent* Teeth that succeed them, which is the most important developmental change that occurs during the period of Childhood, normally commences in the 7th or 8th year: the germs of the new teeth, however, are formed long previously, having their origin in a process of gemmation from the tooth-sacs of the temporary teeth, which takes place at a very early period in the development of the latter.* The three permanent Molars on either side of each jaw, however, have no such origin; since they do not replace temporary teeth. The first pair, which usually make their appearance behind the temporary molars, either contemporaneously-with, or a little anteriorly-to, the first shedding of the deciduous teeth, are really 'milk' teeth, so far as their origin is concerned, since they are developed from primitive tooth-sacs: on the other hand the second true molars, which afterwards come up behind them, are evolved from tooth-sacs, which hold the same relation to those of the first, as the tooth-sacs of the other permanent teeth do to those of the deciduous teeth which they replace; and the third true molars, or *dentes sapientiæ*, bear the like relation to the second. Although the eruption of the true molars is so long postponed, yet the foundation of them is laid at an earlier period; for the papilla of the *first* is distinguishable at the 16th week after conception, that of the second at the 7th month after birth, and that of the third at the 6th year. In the successive replacement of the 'milk' teeth by the 'permanent' set, a very regular order is usually followed. The middle Incisors are first shed and renewed, and then the lateral Incisors. The anterior 'milk' Molars next follow; and these are replaced by the anterior Bicuspid teeth. About a year afterwards the posterior 'milk' Molars are shed, and are replaced in like manner by Bicuspid teeth. The Canines are the last of the 'milk' teeth to be exchanged; in the succeeding year, the second pair of the true Molars appear; but the third pair, or *dentes sapientiæ*, are seldom developed until three or four years subsequently, and often much later.

829. It has been proposed† (and from the evidence adduced in its favour

* See Mr. Tomes' "Manual of Dental Anatomy."

† "The Teeth, a Test of Age, considered with reference to the Factory Children." By Edwin Saunders.

the proposition would seem entitled to considerable attention) to adopt the successive stages in the Second Dentition as standards for estimating the physical capabilities of Children, especially in regard to those two periods which the Factory-Laws render it of the greatest importance to determine—namely, the ages of *nine* and *thirteen* years. Previously to the former, a Child is not permitted to work at all; and up to the latter, it may be only employed during nine hours a day. The necessities or the cupidity of Parents are continually inducing them to misrepresent the ages of their children; and it has been found desirable, therefore, to seek for some test by which the capability of the Child may be determined, without a knowledge of its age. A standard of height has been adopted by the Legislature for this purpose; but upon grounds which, physiologically considered, are very erroneous; since, as is well known, the tallest children are frequently the weakliest. According to Mr. Saunders, the degree of advance of the Second Dentition may be regarded as a much more correct standard of the degree of general development of the organic frame and of its physical powers; and it appears from his inquiries that it may be relied on as a guide to the real age in a large proportion of cases; whilst no serious or injurious mistake can ever arise from its use. It may happen that local or constitutional causes may have slightly retarded the development of the Teeth; in which case the age of the individual would rather be under-estimated, and no harm could ensue: on the other hand, instances of premature development of the Teeth very rarely, if ever, occur; so that there is little danger of imputing to a Child a capability for exertion which he does not possess, as the test of height is continually doing. Moreover, if such an advance in Dentition should occur, it might probably be regarded as indicative of a corresponding advance in the development of the whole organism; so that the real capability would be such as the teeth represent it.—The following is Mr. Saunders's statement of the Ages at which the 'permanent' Teeth respectively appear:—The first true Molars usually present themselves towards the end of the 7th year. Occasionally one of them protrudes from the gum at 6, or more frequently at 6½ years of age; but the evolution of the whole of them may be regarded as an almost infallible sign of the Child being 7 years old. In other instances, where the tooth on one side of the mouth is freely developed, it is fair to reckon the two as having emerged from their capsules; since the development of the other must be considered as retarded. This rule only holds good, however, in regard to teeth in the same row; for the development of the teeth in either jaw must not be inferred from that of the coresponding teeth in the other. With this understanding, the following Table will probably be very near the truth:—

Central Incisors developed at	8 years.
Lateral Incisors	9 „
First Bicuspid	10 „
Second Bicuspid	11 „
Canines	12 to 12½
Second Molars	12½ to 14

The following are the results of the application of this test, in a large number of cases examined by Mr. Saunders. Of 708 children of *nine* years old, 530 would have been pronounced by it to be near the completion of their *ninth* year; having the central, and either three or four lateral, incisors fully developed. Out of the remaining 178, it would have indicated that 126 were 8½ years old, as they presented one or two of the lateral Incisors; and the 52 others would have been pronounced 8 years old, all having three or four

of the central Incisors. So that the extreme deviation is only 12 months; and this in the inconsiderable proportion (when compared with the results obtained by other means) of 52 in 708, or 7⅓ per cent. Again, out of 338 children of 13 years of age, 294 might have been pronounced with confidence to be of that age; having the Canines, Bicuspid, and second Molars, either entirely developed, or with only the deficiency of one or two of either class. Of the 44 others, 36 would have been considered as in their 13th year, having one of the posterior Molars developed; and 8 as near the completion of the 12th, having two of the Canines, and one or two of the second Bicuspid. In all these instances the error is on the favourable side—that is, on the side on which it is calculated to prevent injury to the objects of the inquiry; in no instance did this test cause a Child to be estimated as older or more fit for labour than it really was.*

830. The period of *Youth* is distinguished by that advance in the evolution of the Generative apparatus in both sexes, and by that acquirement of its power of functional activity, which constitutes the state of *Puberty*. Of the principal changes in which this consists, in the two sexes respectively, an account has already been given (§§ 693, 699); and it is merely requisite here to add, that this augmented development can only be rightly regarded as *preparatory* to the exercise of these organs, and not as showing that the aptitude for their exercise has already been fully attained. It is only when the growth and development of the *individual* are completed, that the procreative power can be properly exerted for the continuance of the *race;* and all experience shows that by prematurely and unrestrainedly yielding to the sexual instincts, not merely the generative power is early exhausted, but the vital powers of the organism generally are reduced and permanently enfeebled; so that any latent predisposition to disease is extremely liable to manifest itself; or the bodily vigour, if for a time retained with little deterioration, early undergoes a marked diminution.

831. After the attainment of Puberty, no marked alteration takes place in the organism, save the continuance of its increase in stature, usually for a few years longer; which increase is the chief manifestation of the excess of the germinal capacity, that has not yet expended itself in the building up of the fabric. But so long as this increase is going on there is a want of that solidity and compactness of the organism which seem only attainable when growth has ceased; and the attainment of which, being essential to the highest manifestations of vigour and endurance, marks the final completion of its development. Of this we have the best illustration in the *Osseous* system; whose completion, being postponed until all further *growth* has ceased, may be fairly considered as marking the final stage in the development of the organism, and as therefore characterizing the period of *Adolescence*.—Commencing with the *Vertebral Column*, we find that whilst the 'body' and 'neural

* The value of this test, as compared with that of Height, is manifested by a striking example adduced by Mr. Saunders. The height of one lad, J. J., aged 8 years and 4 months, was 4 feet and ¾ of an inch; that of another boy, aged 8 years and 7 months, was only 3 feet 7¼ inches. According to the standard of height adopted by the Factory Commissioners (namely, 3 feet 10 inches), the *taller* lad would have been judged fit for labour, whilst the *shorter* would have been rejected. The Dentition of the latter, however, was further advanced than that of the former; for he had two of the lateral Incisors, whilst the former had only the central: and the determination of their physical powers, which would have been thus formed, would have been in complete accordance with the truth. The elder boy, though shorter than the other by 5½ inches, possessed a much greater degree both of corporeal and mental energy, and his pulse was strong and regular; whilst that of the younger lad, who was evidently growing too fast, was small and frequent.—An instance even more striking has come under the Author's own observation.

arches' of each vertebra become consolidated in early childhood, the spinous and transverse processes are completed by separate 'epiphyses,' the ossification of which does not commence until after puberty, and the final union of which with the body of the bone may not occur until the age of twenty-five or thirty years. About the same time, there is formed and added to each surface of the body of the vertebra a smooth annular plate of solid bone, which covers a portion that was previously rough and fissured. During this period, the consolidation of the Sacrum is proceeding; the component vertebræ of which remain separate up to about the sixteenth year, and then begin to unite from below upwards, the union of the two highest being completed by about the twenty-fifth or the thirtieth year; whilst at the same time thin osseous plates are formed on either side of the coalesced mass, which seem to represent the epiphyses of the transverse processes of its component vertebræ, and like them are finally joined on to the body of the bone. The ossification and coalescence of the Coccygeal vertebræ takes place at a still later period. Each Rib in like manner has two epiphyses, one for the head and the other for the tubercle; the ossification of which begins soon after puberty, whilst their union with the body of the bone is not completed until some years afterwards. The five pieces of which the sternum consists, though themselves completely ossified, remain separate until after the age of puberty; when their union commences from below upwards, as in the sacrum, not being always completed, however, even in old age, by the junction of the first piece to the rest of the bone. The ossification of the Ensiform cartilage does not commonly begin until after the age of puberty; and it is usually not entirely completed even in very advanced life. The ossific union of the separate elements of the *Bones of the Skull* (§§ 751, 752), is usually completed within a few years after birth: but there are some parts which not unfrequently remain distinct during the greater portion of life, and which may even never coalesce; such is the case with the two halves of the Frontal bone, which often remain permanently divided by a continuation of the sagittal suture, and with the Styloid process of the temporal bone. In the *Upper extremities* we find the Scapula presenting three epiphyses, one for the coracoid process, one for the acromion, and one for the lower angle of the bone; the ossification of which begins soon after puberty, their union with the body of the bone taking place between the ages of twenty-two and twenty-five years. The Clavicle has an epiphysis at its sternal end, which begins to form between the eighteenth and twentieth years, and is united to the rest of the bone a few years later. The consolidation of the Humerus is completed rather earlier; the large piece at the upper end, which is formed by the coalescence of the ossific centres of the head and two tuberosities, unites with the shaft at about the twentieth year; whilst its lower extremity is completed by the junction of the external condyle and of the two parts of the articulating surface (previously united with each other), at about the seventeenth year, and by that of the internal condyle in the year following. The superior epiphyses of the Radius and Ulna unite with their respective shafts at about the age of puberty; the inferior, which are of larger size, at about the twentieth year. The epiphyses of the Metacarpal and Phalangeal bones are united to their principals at about the twentieth year. In the *Lower extremities* the process of ossification is completed at nearly the same periods as that of the corresponding parts of the upper. The consolidation of the Ilium, Ischium, and Pubis, to form the Os Innominatum, by the ossification of the triradiate cartilage that intervenes between them in the acetabulum, does not take place until after the period of puberty; and at this time additional epiphyses begin to make their appearance on the crest of the ilium, on

its anterior inferior spine, on the tuberosity of the ischium, and on the inner margin of the pubes, which are not finally joined to the bone until about the twenty-fifth year.

832. The rapid increase in *Viability* which shows itself in both sexes up to the age of puberty, its rapid decline from that point, and its subsequent increase in the male up to the age of thirty, have been already pointed out (§ 761). The disorders to which the organism is most subject during the several periods which have now been considered, are by no means the same for each. In early Childhood, when there is a great demand for the activity of the Digestive and Assimilative functions, and these have to be exercised upon nutriment to which their organs are not yet accustomed, we find derangements of those organs to be among the most common of all maladies; these may be serious enough in themselves to constitute dangerous and even rapidly fatal diseases; but even when they do not take these acute forms, a foundation is often laid, in habits of perverted Nutrition thence arising, for disorders of a more chronic nature (especially those depending on the Tubercular diathesis), which may not manifest themselves for many years afterwards. The peculiar activity of the nervous centres, which is prolonged from Infancy into early Childhood, involves a continued liability to derangements of *their* nutrition or of their functions; and thus it happens that in young children of scrofulous temperament, it is either in the mesenteric glands, or in the brain or its membranes, that tubercular deposit first takes place. The second Dentition, like the first, is often accompanied with a great deal of constitutional disturbance; especially in such individuals as are suffering from defective Nutrition, or from an irritable state of the Nervous System. In the former case there is a special proneness to Tubercular disease;* in the latter, to Epilepsy, Chorea, or some other form of disorder of the nervous centres, the connection of which with Dentition is shown by its abatement when that epoch has passed. A large part of the sickness and mortality, however, which presents so high a rate during the whole period of Childhood, is due to various forms of Zymotic disease, especially the Exanthemata and Infantile Remittent Fever, and to their *sequelæ*.†—The attainment of Puberty in the Male sex is not usually attended with any specific tendency to disease; nor would it probably be in the Female, if her mode of life were more accordant with the rules of health. Although disorder of the Menstrual function is one of the most common phenomena of female youth, yet it is undoubtedly to be looked upon more frequently as a symptom of general defect of nutrition (and especially of an impoverished condition of the blood), than as itself constituting a disease. The extraordinary reduction in the probability of life, indicating a large mortality, during the years which immediately succeed puberty, seems to depend in great degree, in the Male, upon the premature use of his generative powers, and upon his entrance upon the active employments of life before his constitution has received that invigoration which results from the completion of his bodily development; whilst in the female it is very commonly attributable to the accumulation of unhealthy influences, which begin to 'tell' upon the powers of her system, when its germinal capacity no longer

* It is a very significant circumstance, that of the many specimens of the Anthropoid Apes which have been brought alive into this country, not one has survived its second dentition; and that, in almost every case, it has been by tubercular disease that their lives have been thus prematurely cut-off.

† The effects of affluence and poverty on the duration of life at this period are remarkably shown by the deductions of Caspar of Berlin, who states as the result of his inquiries that 1000 children born in the families of affluent persons, 911 attained the age of 15 years; whilst of 1000 paupers, only 584 survived to that age. (Béclard, "Physiologie," 1862, p. 594.)

ministers to its active regeneration. It is *then*, in both sexes, though from causes whose immediate nature is different, that the Tubercular diathesis is prone to develop itself with peculiar intensity, and that, by fixing upon the Respiratory organs, it produces the most rapidly-fatal alterations in structures whose integrity is essential to life.

833. *Period of Maturity.*—The cessation of growth and the completion of the developmental process, which indicate the attainment of *Manhood*, are accompanied by a marked increase in the general vigour of the organism, and by a special augmentation in the power of *endurance* in the exercise of the Animal faculties. With the exception of those parts of the fabric whose utility was confined to the earlier periods of its development, we find every organ now presenting its greatest capacity for sustained activity; and thus it is from the characters which each presents at this period, that we base our ideas of its *typical* perfection of structure and composition. All the previous changes which the organism has undergone, both as a whole and in its separate parts, concur to the attainment of this perfection, as we have especially seen in regard to the evolution of the solid framework of the body; and every subsequent change, as we shall presently perceive (835), involves a deterioration from it. The whole *nisus* of development, during this period, appears to be directed towards the *maintenance* of the organism in the state which it had acquired at its commencement; by the regeneration of its tissues as fast as they undergo disintegration, and by the renovation of its vital force in proportion as this is expended. There is no longer any capacity for the production of new organs, and comparatively little for the augmentation of those already existing; the increase of the Uterine and Mammary structures, during the period of gestation, being the most important examples of formative power, and these presenting themselves in the sex in which there is least of nervo-muscular activity and of general vigour. We should infer then, that the 'germinal capacity' is now on the decline; and this further appears from the diminished energy and completeness with which the reparative processes are performed, as compared with the mode in which they are executed during the period of growth. There is consequently a less demand for alimentary material (allowance being made for the augmented bulk of the body) than during the previous periods; and the dependence of life upon a constant supply of aliment is far less close. Moreover, the ordinary rate of waste or degeneration of tissue is now much less rapid than during the period of growth; for we have seen that decay and removal, in the latter case, are among the very conditions of increase; whilst in the former, they proceed, for the most part, only from the expenditure of the vital powers of the tissues, consequent upon *their* functional activity. Hence it is upon the degree in which the *Animal* powers are exercised, that the demand for food chiefly depends in the Adult; the sole purpose of the Organic or Vegetative operations being (so to speak) to keep the apparatus of Animal life, now fully developed, in working order. The relative activity of the different parts of this apparatus is now somewhat modified. The *observing faculties* no longer possess the same pre-eminence; the *emotional sensibility* is less readily excited; but the *intellectual powers* now act, in the modes which have become habitual to them, with a sustained vigour and completeness which they never previously possessed. And so, whilst the muscles are not so easily excited to contraction, and new combinations of movement are acquired with far more difficulty than during the period of growth and development, the force which they can generate by their contraction is augmented, and this force can be kept-up for a much longer time in adults than in younger subjects.

834. The duration of the period over which this 'maintenance' may be protracted, without any sensible deterioration, depends in great degree upon the due observance of all the conditions of health. If the various mental and bodily faculties are duly exercised, without being overtasked—if an amount of sleep adequate to their periodic renovation be regularly taken—if a sufficient but not excessive quantity of wholesome food be ingested at appropriate intervals—if the functions by which the blood is prepared, and those by which it is kept in purity, be duly performed—if all such noxious agents as foul air, strong alcoholic liquors, and tobacco-smoke, be kept at a distance—and there be no constitutional predisposition to disease on the one hand, nor any exposure to extraneous morbific causes on the other—it may be fairly anticipated that the bodily and mental vigour may be sustained with little deterioration during a long succession of years. The circumstances that most tend to premature decline, are, on the one hand, excessive exertion either of the mental faculties or of the generative power; or, on the other, undue indulgence in food, or in stimulating drinks, or in any practice that tends to disorder the Organic functions, especially by exciting them to undue activity. Every one who, in *any* of these modes, may "live too fast," is almost certain to pay the penalty in an abbreviation of his term of vigorous activity; which may be either brought to a sudden and final close by fatal disease, or may be prematurely reduced by more gradual decay. And this tendency will of course be more decided, the greater is the amount, and the larger the combination, of those departures from the Laws of Health which give rise to it.

835. *Period of Decline.*—The *decline of life* exhibits a much more obvious diminution of the whole vital power of the organism; for not only is its formative activity now greatly reduced, but its nervo-muscular energy and general vigour progressively diminish, and its generative power becomes enfeebled, or ceases entirely (§§ 693, 701). Of this diminution in formative power we have evidence in the entire absence of any attempt at new development, in the less perfect and more tedious manner in which the losses of substance occasioned by disease or injury are recovered from, and in the gradual deterioration of the organism in general. The tissues which are rendered effete by their functional activity, are not any longer replaced in their normal completeness; for either the quantity of new tissue is inadequate, so that the bulk of the organs is obviously reduced; or their quality is rendered imperfect by the production of structures in various phases of degeneration, in place of those which had been previously developed in the fullest completeness. The inferiority of Nervo-muscular energy and of general vigour are thus evidently the result of the deficiency, and not (as in the period of growth) of the excess of formative power; and in proportion as the 'waste' of the tissues, consequent upon their functional activity, is more rapid than their renovation, a progressive loss of substance must take place. The forms of Degeneration most commonly met with in advanced age, are the *fatty* and the *calcareous*. The former is extremely prone to show itself in those organs whose integrity of structure is peculiarly important to health, and whose deterioration interferes directly with the *vital* properties of their component tissues. Thus we observe it in the Muscular apparatus generally, but pre-eminently in the walls of the Heart; and in proportion as its contractile fibre has been replaced by particles of fat, must the vital energy of any muscle be lowered. So, again, we find the same degeneration in the Liver, Kidney, and other parts of the Glandular apparatus; the proper secreting action of which is impaired in the ratio of the substitution of fat for

the proper Glandular elements. But it may also lead to most serious derangements of the vital functions, by its interference with the purely mechanical actions of certain parts of the organism; thus, fatty degeneration of the walls of the Blood-vessels is one of the most frequent causes of those extravasations of blood in the nervous centres, which give rise to the apoplexy and to the various forms of paralysis so common among the aged; and the same change occurring in the Bones, gives them that peculiar brittleness which they frequently exhibit in advanced periods of life. The general decline of the vital powers, which has received the name of 'climacteric disease,' appears traceable to the same source.*—The tendency of the calcareous degeneration (which especially affects the Cartilaginous and Fibrous tissues) is almost exclusively to interfere with the *mechanical* adaptations of the organism; producing an injurious rigidity in various structures which require a greater or less amount of flexibility for the normal performance of their functions. Thus it is very common for the cartilages of the ribs to become ossified in advanced life, so as to interfere with the free movement of the walls of the thorax; and the thyroid cartilages of old people are frequently converted into bone, producing a roughness of the voice, and deficiency of the power of modulating it. The intervertebral substance (which is partly cartilaginous and partly fibrous) not unfrequently becomes solidified in the lumbar region, as do also the spinal ligaments, so that several of the lower vertebræ are firmly anchylosed to each other and to the sacrum; and a like change often takes place in the pelvic articulations, so that the pelvis and the lower part of the spine become one continuous mass of bone, destitute of flexibility or yieldingness in any part. In like manner the cranial sutures often become obliterated, and calcareous deposits occur in the duplicatures of the dura mater forming the falx and tentorium. A large amount of this kind of change may take place without any serious interference with the organic functions, although it tends to curtail the Animal powers. When the calcareous degeneration, however, extends itself to the vital organs, the interruption which it occasions in their actions may be fatal; thus, next to fatty degeneration, there is probably no more frequent cause of failure of the heart's action, or of extravasation from the blood-vessels, in old persons, than ossification of the valvular apparatus of the former, depriving it of the flexibility which is essential to its proper action, or the fibrous walls of the latter, imparting to them a brittleness which predisposes to rupture.†

836. Thus, then, with the advance of Old Age, the organism becomes progressively more and more unfit for the active performance of its vital operations; a gradual weakening is observable in the Mental as well as in the Corporeal energy; and a retardation becomes obvious in the current of Organic life. The mind is far less active than in the periods of Maturity; the perceptions are dull, the feelings comparatively obtuse (save where some dominant emotion has gained possession, through the previous habit of yielding to it), the intellectual powers cannot be so readily put in action, and the imagination loses its vividness. There are few instances in which any great works, either literary or artistic, have been executed after the age of threescore. Still the experience of a long life gives value to the judgment; and the counsels of the old, where the bearings of the question can be fully

* See Gulliver in the "Transact. of Roy. Med.-Chir. Soc.," 1843; and in "Edin. Med. and Surg. Journ.," 1843; Mr. Barlow's 'General Observations on Fatty Degeneration,' in the "Medical Times and Gazette," May 15, 1852.

† A good account of these changes will be found in the "Practical Treatise on the Diseases and Infirmities of Advanced Life," by Daniel Maclachan, M.D., 1863.

understood, deserve the respect of the young, more especially in cases where temporary ardour of feeling tends in the latter to supersede the dictates of their calmer reason.—The mental torpor is correlated, there seems no reason to doubt, with changes in the condition of the Nervous substance, which impair its original activity; and like changes, occurring in the Muscular substance, diminish its capacity for physical exertion. Hence there is, on the one hand, a marked diminution in the demand for food; on the other, a like diminution in the rate of the excretory processes, as is seen especially in the exhalation of carbonic acid (§ 287) and in the excretion of Urea: and in accordance with all these reductions, there is a greatly diminished power of sustaining the heat of the body, the temperature of which consequently becomes liable to a serious depression from external cold. This retardation of vital activity gradually becomes more and more marked, until, if neither accident nor disease should intervene, the current stops of itself; the formative power seems to undergo a progressive exhaustion, until no assistance from artificial heat, no supply of the most nutritious food, can any longer avail for the generation of new tissue; the nervo-muscular energy gradually declines, until at last even those actions on which the circulation and respiration entirely depend can no longer be performed; and with the cessation of these functions, the Life of the entire organism becomes extinct. —Such we may consider to be the mode in which *Death* normally occurs. Various abnormal influences, however, remain to be considered, which may bring about this final result at an earlier period, and in different modes (CHAP. XXI.).

CHAPTER XXI.

OF DEATH.

837. We have seen it to be inherent in the very nature of Vital Action, that it can only be sustained during a *limited period* by any Organized body; for although the duration of certain structures may be prolonged, and their vital properties retained, almost indefinitely, yet this is only when the withdrawal of all extraneous agencies has reduced them to a condition of complete inactivity. The Organized fabric, in fact, is at the same time the *instrument* whereby Vital Force is exercised, and the *subject* of its operation; and of this operation, *decline* is no less a constituent part than *development*, and *Death* is its necessary sequence. Hence, in the performance of each one of those Functions whose aggregate makes up the Life of Man, the particular organ which ministers to that function undergoes a certain loss by the decline and death of its component tissues; and this the more rapidly in proportion to the activity of the changes which are effected by their instrumentality. But if the regenerative processes be also performed with due vigour, no deterioration of the organ is manifested, since every loss of substance is compensated by the production of an equivalent amount of new and similar tissue. This regenerative power, however, gradually diminishes with the advance of years; and thus it happens that the entire organism progressively deteriorates (§ 835), and that Death at last supervenes from a general failure of the vital powers, rather than from the perversion or cessation of any one class of actions in particular.

838. But Death may occur at any period of Life, from some local interruption produced by disease or injury in the regular sequence of vital actions; such interruption extending itself from the part in which it commences to the

organism in general, in virtue of that intimate mutual dependence of one function upon another, which is characteristic of all the higher orders of living beings. The death of the body as a whole, which may be appropriately designated *Somatic** death, becomes a necessary consequence of the death of a certain part of it, or *Molecular* death, only when the cessation of activity in the latter interferes with the elaboration, the circulation, or the depuration of the Blood, which supplies not merely the nutritive *pabulum* to every part of the organism, but also the oxygen which is essential to the activity of the Nervo-muscular apparatus. Thus, even in the higher animals, the death or removal of the limbs, although they may constitute (as in Man) a large proportion of the fabric, is not necessarily fatal; because it involves no interruption, either in the nutritive operations of the viscera, or in the sensorial functions of the brain.† On the other hand, the destruction of a certain minute portion of the Nervous centres, or such a lesion of the Heart's structure as would be trivial in almost any other organ, may be the occasion of immediate death; because these changes arrest the Respiratory movements, or interfere directly with the action of the Heart, so as to bring the flow of blood to a stand. It sometimes happens, however, that life may be prolonged after the death or removal of some important organ, in consequence of the power which some other possesses of discharging its functions; thus we find that in Man the kidneys seem occasionally to take upon themselves the elimination of the constituents of bile from the blood (§ 368); and in the Frog the skin can perform part of the office of the lungs, so as to effect the aëration of the blood in a sufficient degree to prolong life for some time, unless the temperature be elevated.‡

839. But although the vital activity of every part of the body is dependent upon a due supply of circulating fluid, yet this dependence is usually not so close as to involve the *immediate* suspension of vital activity, or *Molecular Death*, in every part, whenever the general Circulation shall have been brought to a stand. For we have have distinct evidence of the persistence of vital changes in various organs and tissues of the body, after the death of the body at large; as is manifested in the performance of ciliary and of muscular movements, in acts of secretion and perhaps even of nutrition,§ in the maintenance of the local circulation, and in the generation of animal heat (§ 384); and the fact is even yet more remarkably manifested in the reunion (even after the lapse of some hours) of parts that have been entirely severed, such as

* This term was first suggested by Dr. Prichard, in place of the less accurate term 'systemic' which was previously in use. (See "Cyclop. of Anat. and Physiol.," vol. i. p. 791.)

† The Author has been informed by Dr. Daniell that it is not at all uncommon in Negroes who are in the last stage of the adynamic fevers of the African coast, for death and decomposition to extend gradually upwards from the extremities to the trunk; so that the former may be in a state of absolute putrescence, before the respiration and circulation have been brought to a stand: and he learns from Prof. Jackson, of Philadelphia, that he has more than once witnessed the same occurrence.

‡ That such cannot take place in Man, is due not merely to the far less complete adaptation of his skin for the aëration of the blood, but also to the difference in the type of his circulation, which causes the arrest of blood in the pulmonary vessels to produce a stagnation of the entire current.

§ Thus Mr. T. Bell mentions ("History of British Reptiles," p. 61), that having been engaged in the careful dissection of the poison-apparatus of a large Rattlesnake, although the animal had been dead for some hours, and the head had been taken off immediately after death, yet the poison continued to be secreted as the dissection proceeded, so as to require to be occasionally dried off with a bit of sponge.—A growth of Hair is said to have been noticed in several instances after death; and if the temperature of the surrounding medium be not too low for the vital activity of the hair-bulbs, there seems no adequate reason why this should not take place.

fingers or toes, noses or ears, by adhesion between the cut surfaces when brought into apposition, which could not take place if the severed part were already *dead*.

840. The permanent and complete cessation of the Circulating current, which essentially constitutes *Somatic* Death, may be directly or indirectly consequent upon several distinct causes. In the *first* place, it may be due to failure in the propulsive power of the Heart, which constitutes *Syncope*. This failure may occur either (*a*) in consequence of a loss of the proper irritability of the Muscular tissue, or (*b*) through the supervention of a 'tonic spasm,' the organ remaining rigidly contracted without its usual alternation of relaxation. The phenomena attending death in the two cases are not dissimilar, when the loss of irritability is sudden and immediate (as when it arises from violent impressions on the nervous system); for the individual suddenly turns pale, falls back or drops down, and expires with one gasp. But under the former condition, the heart is found *flabby*, sometimes empty, sometimes distended with blood, both cavities being equally filled; whilst in the latter the heart is contracted and hard, containing little or no blood, as when in the state of *rigor mortis*.—The cause of the loss of irritability, when sudden, usually lies in the influence of a 'shock' transmitted through the Nervous system, and originating either in some severe lesion of its central organs or of its peripheral expansion (§ 227), or in a deficiency of its supply of blood or diminution of its usual pressure (such as is produced by rapid detraction of blood, especially in the erect posture, by the rapid removal of the fluid in ascites without the substitution of artificial pressure, or by suddenly rising into the erect posture, after prolonged recumbency,* still more, after long stooping), or in some powerful mental emotion, either exciting or depressing. A more gradual effect of the same kind is produced by severe lesions of the internal organs (such as rupture of the uterus), which often prove fatal by the general 'collapse' thus induced, rather than by the disturbance which takes place in their own proper functions; and this seems to be the usual *modus operandi* of corrosive poisons, whose effect upon the heart's action resembles that produced by severe burns of the surface in children. The influence of the proper *sedative* poisons, however—such as digitalis, tobacco, aconite, and upas—seems to be directly exerted, through the blood, upon the tissue of the heart itself; and the same is probably the case with some of those 'morbid poisons,' whose introduction into the system gives rise to diseases of the most intensely adynamic type, such as Malignant Cholera, in which the 'collapse' is out of all proportion to any local lesion. But, again, the loss of the Heart's irritability may be a gradual process, resulting from the deterioration of its tissue by fatty degeneration or by simple atrophy; and this last condition may be due to deficiency of blood, as happens in chronic starvation and diseases of exhaustion, in which the failure of the circulation seems due to the weakening of the heart's power and to the lowering of the quantity and quality of the blood, acting as concurrent causes, the condition thus induced being appropriately designated *Asthenia*. In all cases it is to be observed that when the Vital powers have been previously depressed, a much slighter impression on the Nervous system is adequate to produce Syncope, than would be required when it is in a state of full vigour.—The causes of the tonic spasm of the heart have not been clearly made out; but it seems producible, like the

* Hence it is that great caution should be exercised in allowing patients who are convalescent from acute diseases to rise into the erect position, many cases of fatal syncope having been thus induced. The state of general debility, and the continued recumbency both favour this result, especially in persons advanced in life.

more common form of Syncope, by agencies operating through the Nervous system; thus it has supervened upon the ingestion of a large quantity of cold water into the stomach.

841. Somatic Death may be occasioned, *secondly*, by an obstruction to the flow of blood through the capillaries of the lungs, constituting *Asphyxia* (§ 299); and this may be consequent upon a disordered state of the lungs themselves, or upon suspension of the respiratory movements through affections of the Nervous centres. It is in this mode that most fatal disorders of the Nervous System produce death, except when a sudden and violent impression occasions a cessation of the heart's power; thus in Apoplexy, Narcotic Poisoning, &c., death results from the paralyzed condition of the Medulla Oblongata; whilst in Convulsive diseases, the fatal result generally ensues upon a spasmodic fixation of the respiratory muscles.—*Thirdly*, Somatic death may be occasioned by a disordered condition of the *Blood* itself, which at the same time weakens the power of the Heart, impairs the activity of the Nervous system, and prevents the performance of those changes in the systemic Capillaries, which afford a powerful auxiliary to the circulation. This is death by *Necræmia*.*—*Fourthly*, Somatic death may result directly from the agency of *Cold*, which stagnates *all* the vital operations of the system. Where the cooling is due to the agency of an extremely low external temperature, which acts first upon the superficial parts, there is reason to think that the congestion of the internal vessels thereby induced occasions a torpid condition of the Nervous centres, and that the cessation of the Circulation is immediately due to Asphyxia. But when the cooling is gradual, and the loss of heat is almost equally rapid throughout, it is obvious that the stagnation must be universal, and that no cessation of activity in any one part is the occasion of the torpor in the functions of the remainder. It is in this manner that death ordinarily results from Starvation, and not by the weakening of the heart's action, as commonly supposed; the proofs of this have been already stated (§ 389).

842. As a general rule, we find that the more active the changes which normally take place in any tissue during life, the more speedily does its *Molecular* Death follow Somatic Death, the requisite conditions of its vital action being no longer supplied to it. Thus we observe that in Cold-blooded animals, the supervention of Molecular upon Somatic death is much less speedy than it is in Birds and Mammals. This seems due to two causes. In the first place, the tissues of the former, being at all times possessed of a lower degree of vital activity than those of the latter, are disposed to retain it for a longer time; according to the principle already laid down. And secondly, as the maintenance of a high temperature is an essential condition of the vital activity of the tissues of Warm-blooded animals, the rapid cooling of the body after Somatic death is calculated to extinguish it speedily; and that this cause has a real operation, is evinced by the influence of artificial warmth in sustaining the vital properties of separated parts.—The rapidity, however, with which Molecular death follows the cessation of the general circulation, will be influenced by a variety of causes; but especially by the degree in which the condition of the solids and fluids of the body has been impaired by the mode of death. Thus in Necræmia, Asthenia, and death by gradual cooling, Molecular and Somatic Death may be said to be simultaneous; and the same appears to be true of death by sudden and violent impressions on the Nervous system (§ 227). But in many cases of death by causes which operate by producing a more gradual Syncope or Asphyxia, the

* See Dr. C. J. B. Williams's "Principles of Medicine," 3rd edit., p. 553.

tissues and blood having been previously in a healthy condition, Molecular death may be long postponed; and we cannot be quite certain that it has supervened until signs of actual decomposition present themselves.

843. When Molecular death takes place in an isolated part, it must result from some condition peculiar to that part, and not primarily affecting the body in general. Thus we may have Gangrene or Mortification of a limb as a direct result of the application of severe cold, or of an agent capable of producing chemical changes in its substance, or of violent contusions occasioning mechanical injury; or, again, from an interruption to the current of nutritive fluid; or, further, from some ill-understood stagnation of the nutritive process, which manifests itself in the spontaneous death of the tissues without any assignable cause, as in some cases of senile gangrene. Sometimes we are enabled to trace this stagnation to a disordered condition of the circulating fluid; as in the gangrene resulting from the continued use of the 'ergot' of rye or wheat; but we can give no other account of the almost invariable commencement of such gangrene in the extremities, than we can of the selection of lead, introduced into the blood, by the extensors of the fore-arm.—If Mortification or Molecular Death be once established in any part, it tends to spread, both to contiguous and to distant portions of the body. Thus we have continually to witness the extension of gangrene of the lower extremities, resulting from severe injury or from the use of the ergot, from the small part first affected, until the whole limb is involved; and this extension is easily accounted for, by our knowledge of the tendency of organic substances in the act of decomposition to produce a similar change in other organic substances subjected to the influence of proximity to them. And the propagation of the gangrenous tendency to remoter parts is obviously due to the perversion of the qualities of the Blood, which results from a similar cause.*

844. It is quite certain that an *apparent* cessation of *all* the vital functions may take place, without that entire loss of vitality which would leave the organism in the condition of a *dead* body, liable to be speedily disintegrated by the operation of chemical and physical agencies. The state of Syncope is sometimes so complete that neither can the heart's action be perceived nor any respiratory movements be observed, all consciousness and power of movement being at the same time abolished; and yet recovery has spontaneously taken place, which could scarcely have been the case if *all* vital action had been suspended.—It is not a little remarkable, that certain individuals have possessed the power of *voluntarily* inducing this condition. The best authenticated case of this kind is that of Col. Townsend, which was described by Dr. George Cheyne,† who was himself the witness of the fact. But statements have also been made respecting the performances of certain Indian Fakeers, which are far more extraordinary; it being demonstrated, if these assertions are to be credited,‡ that the Human organism may not only be

* On the proximate causes of Death, see especially the Art. 'Death,' by Dr. Symonds, in the "Cyclop. of Anat. and Phys.," vol. i.; the first chapter of Prof. Alison's "Outlines of Pathology and Practice of Medicine;" and Dr. C. J. B. Williams's "Principles of Medicine," 3rd edit., pp. 536–557.

† See his "Treatise on Nervous Diseases," p. 307.

‡ See a collection of these cases, directly obtained from British officers who had been eye-witness of them in India, by Mr. Braid, in his "Observations on Trance, or Human Hybernation," 1850.—In one of these, vouched-for by Sir Claude M. Wade (formerly political agent at the Court of Runjeet Singh), the Fakeer was buried in an underground cell, under strict guardianship for *six weeks*; the body had been twice dug up by Runjeet Singh during the period of interment, and had been found in the same position as when first buried.—In another case, narrated by Lieut. Boileau in his "Narrative of a Journey in Rajwarra, in 1835," the man

voluntarily reduced to a state resembling profound collapse, in which there appears to be nearly a complete suspension of all its vital operations, but may continue in that condition for some days or even weeks, until, in fact, means are taken to produce resuscitation.—Another form of apparent death, the existence of which appears to be well-authenticated, is that sometimes designated as 'Trance' or 'Catalepsy,' in which there is a reduction of all the Organic Functions to an extremely low ebb, but in which Consciousness is still preserved, whilst the power of voluntary movement is suspended; so that the patient, though fully aware of all that is being said and done around, is unable to make the least visible or audible sign of life.* It is impossible, in the present state of our knowledge, to give any satisfactory account of these states; but some light appears to be thrown upon them by certain phenomena of artificial somnambulism, 'hypnotic' or 'mesmeric' (§ 539); for, in this condition, there is sometimes an extraordinary retardation of the respiratory movements and of the pulsations of the heart, which, if carried farther, would produce a state of complete collapse; and its self-induction is suspected by Mr. Braid to be the secret of the performance of the Indian Fakeers just referred to.

845. The signs by which *real* is certainly distinguishable from *apparent* Death, are not numerous, a large proportion of those commonly relied on being fallacious; but they are conclusive.—In the first place, it is to be remarked that no reliance is to be placed, for the reasons already mentioned, upon the apparent cessation of the Heart's action and of the Respiratory movements; since the reduction of these to so low a condition that they are no longer distinguishable, is by no means incompatible with the persistence of vitality. It has been suggested, however, that the persistence of the circulation in its feeblest degree may be rendered manifest by the application of a ligature to a finger, which may become swollen on the distal side if the heart still continues to act.† A surer test, however, is afforded by the condition of the *Muscular* substance; for this gradually loses its irritability after real Death, so that it can no longer be excited to contraction by electrical or any other kind of stimulation; and the loss of irritability is succeeded by the appearance of cadaveric rigidity. So long, then, as the muscle retains its irritability and remains free from rigidity, so long we may say with certainty that it is *not dead;* and the persistence of its vitality for an unusual period affords a presumption in favour of the continuance of some degree of vital action in the body generally; whilst, on the other hand, the entire loss of

had been buried for ten days in a grave lined with masonry and covered with large slabs of stone, and strictly guarded; and he assured Lieut. Boileau that he was ready to submit to an interment of a twelvemonth's duration if desired.—In a third case, narrated by Mr. Braid, the trial was made under the direct superintendence of a British officer, a period of nine days having been stipulated-for on the part of the devotee; but this was shortened to three at the desire of the Officer, who feared lest he should incur blame if the result was fatal.—The appearance of the body when first disinterred, is described in all instances as having been quite corpse-like, and no pulsation could be detected at the heart or in the arteries; the means of restoration employed were chiefly warmth to the vertex and friction to the body and limbs.—It may be remarked that the possibility of the protraction of such a state (supposing that no deception vitiates the authenticity of the narratives referred to) can be much better comprehended as occurring in India than as taking place in this country; since the warmth of the tropical atmosphere and soil would prevent any serious loss of heat, such as must soon occur in a colder climate, when the processes whereby it is generated are brought to a stand.

* Several such cases are recorded in Dr. H. Mayo's "Letters on the Truths contained in Popular Superstitions," and also by Mr. Braid, op. cit.

† See also Norris, Humphry and Turner's "Journal of Anat. and Physiology," vol. i. p. 217.

irritability, and the supervention of rigidity, afford conclusive evidence that death has occurred. The most satisfactory proof, however, is given by the occurrence of *putrefaction;* this usually first manifests itself in the blue-green coloration of the cutaneous surface, especially the abdominal; but it speedily becomes apparent in other parts, its rate being usually in some degree of accordance with the external temperature, though also much influenced by the previous condition of the solids and fluids of the body, these having been sometimes left by diseased actions in a state that renders them peculiarly prone to disintegration.

846. With the final restoration of the components of the Human Organism to the Inorganic Universe, in those very forms (or nearly so) in which they were first withdrawn from it, the Corporeal Life of Man, of which it has been the object of the foregoing Treatise to sketch the leading features, comes to a final close. But the Death of the Body is but the commencement of a new Life of the Soul; in which (as the religious physiologist delights to believe) all that is pure and noble in Man's nature will be refined, elevated, and progressively advanced towards perfection; whilst all that is carnal, selfish, and degrading, will be eliminated by the purifying processes to which each individual must be subjected, before Sin can be entirely subjugated, and Death can be completely "swallowed up of Victory."

APPENDIX.

Composition of BONE :—

	Per Cent.
The bones of a 3 days old child lost by incineration	38·81
14 „ „ (bones of skull)	35·33
„ „ „ (femora)	32·47
6 years old „ compact bone of diaphysis . .	34·49
„ „ „ cortical layer of epiphysis . .	36·84
Woman, æt. 22, compact substance of femur . .	35·4
„ „ 80 „ „ . .	35·4

The Residue of bone after incineration was found by Heintz to contain, per cent. :—

	I.		II.
Ca	38·59	...	38·56
PO_4	53·75	...	53·87
CO_2	5·44	...	5·51
Fl	1·74	...	1·58
Mg	0·48	...	0·48

Dry dentine of the ox was found by Aeby to contain :—

PO_4, 40·47 per cent. ; CO_2, 0·97 ; Ca, 28·74 ; Mg, 0·15. Organic compounds, 27·70 per cent., with traces of iron and sulphuric acid. The ivory contained PO_4, 55·15 per cent. ; CO_2, 3·32 ; Ca, 37·28 ; Mg, 0·21. Organic substances, 3·60.

Composition of Mixed SALIVA :—

Water	994·10	...	995·16	...	994·698
Solids	5·90	...	4·84	...	5·302
Soluble organic compounds.	1·42	...	1·34	...	3·271

Agraphia, 678 *note*.
Air-cells of the lungs, 345.
Air, composition of, 368 *note;* total quantity breathed, 368; effects of rarefaction of, on man, 376; alterations in, by respiration, 368 (see RESPIRATION); effects of insuffi-

cient supply of, 376; amount required, 368; ventilation of, 392; effects of breathing impure, 385–391; compressed, influence of, on pulse, 303.
Air, compressed, effect of respiration of, 375.
Air-sacs of the lungs, 345.
Air-vesicles of the lungs, 346.
Airy, Prof., on astigmatism, 727.
Ajtai, on gustatory nerves, 710 *note*.
Aladoff, on glycogeny, 452, 453.
Alalia, 679.
Albert, temperature of blood in heart, 224.
Albertoni, on ferments eliminated by the kidneys, 469; on cerebrum, 673 *note*; effect of pepsin on the coagulation of blood, 251.
Albinoism, 984.
Albrecht, on nerve stimuli, 548 *note*.
Albumin, compounds of, 59; proportion of, in different fluids and solids, 60; tests for, 60; importance of, in diet, 94–100; digestion of, 148; gastric digestion of, 148; pancreatic digestion of, 149; normal proportion of, in Blood, 254; variations of, in disease, 267; uses of, 59, 411; transudation of, 331; conversion of, into fat, 413; alkali, 971; casein, 971.
Albuminose, 263.
Albuminous constituents of food, 59, 94; importance of admixture of, with oil and starch, 94; digestion of, 148, 163; influence of, on excretion of urea, 462; metamorphosis of, in the body, 411.
Albuminuria, 462.
Alcock, Dr., on lingual nerves, 590.
Alcohol, quantity of, consumed in England, 106; injurious results of habitual use of, 106, 421; on kidney, 472, 487; use of, in fever, 511.
Alcoholic fermentation, 65.
Aleuron, 64, 73.
Alexis St. Martin, 122; digestion in, 150.
Alfourou race, 1010.
Aliment, 92, see *Food*.
Alimentary canal, development of, 931.
Alison, Prof., on asphyxia, 391 *note*; on suppression of bile, 445; on guiding sensation, 638; on rapidity of muscular movements, 825; on death, 1032 *note*; on muscle contraction, 807.
Alkali albumin, 62.
—— albuminate, 62.
Alkalies, effect of, on urine, 485.
Alkaline phosphates, in blood, 255; in urine, 482.
———— sulphates, in urine, 482.
Alkalinity of urine, causes of, 485.
Alkophyr, 149.
Allantoin, 74, 412, 468, 469.
Allantois, development and uses of, 909, 917, 925, 938.
Allbutt, Dr. Clifford, on animal heat, 501.
Allen and Pepys, on elimination of carbonic acid, 369.
Althaun, on intracranial pressure, 339.
Alveoli of lungs, 345.
Alveolar passages of lungs, 344.
Amanitin, 81.
Amativeness, 651.
American races, 1007.
Ametropia, 726.
Amido-caproic acid, 75.
Amido-sulphoperuvic acid, 80.
Amidulin, 83.
Ammon, Von, on influence of nerves on secretion, 861 *note*.
Ammonia, exhalation of, by lungs, 369, 383.
———— excretion of, by the urine, 483.
Ammonium sulphide, effects of inhalation of, 384.
Amnesia, 679.
Amnion, 917; development of, 920; structure of, 926; liquor of, 926.
Amœbæ, 33.
Amphioxus, nervous system of, 536.
Amylaceous substances, digestion of, 137, 161,
Amyloid degeneration, 73.
Amyloid substance of the liver, 449–456; see *Glycogeny*.
Amylolytic ferments, 69, 161.
Amylopsin, 69, 161, 789.
Anacrotic elevation of pulse tracing, 314.
Anæmia, state of blood in, 266; a cause of death from cold, 509.
Anæsthesia, 609; production of, 675.
Analgesia, 608.
Ancon breed of sheep, 993 *note*.
Andaman Isles, Mincopie race of, 1093 *note*.
Andral, M., on composition of blood in cachexia, 267; on relative capacity of cardiac ventricles, 274; on temperature in disease, 505; in infants, 499; on cerebellum, 649.
Andral and Gavarret, MM., on alteration of blood in disease, 264, 265; on respiration, 370, 378.
Anelectrotonus, 558–559.
Anerythropsia, 754 *note*.
Angelon, on consanguineous marriages, 904 *note*.
Angina pectoris, cause of, 295 *note*.
Animal cells, 34.
Animal heat, 497, see *Heat*.
Anoplotherium, composition of bones of, 50.
Ano-spinal centre, 609.
Ansa Vieusenii, 296.
Anselmino, on solids in sweat, 490 *note*.
Anstie, Dr. E., on alcohol, 107; on stimulants and narcotics, 696 *note*.
Antero-lateral columns of spinal cord, 598.
Antialbuminate, 149.
Antialbumose, 149.
Antiaris Toxicaria, action of, on Heart, 297.
Antipepton, 149, 163.
Antiperistaltic action, 121.
Antlers of deer, exuviation of, 419.
Aorta, development of, 923, 927.
Aperistalsis, 126.
Apes, differences between man and, 15.
Aphasia, 678.

Aphides, multiplication of, 5.
Apnœa, 358; influence of, on muscles and nerves, 793.
Apomorphin, effects of, 125.
Apparatus, Pettenkofer's respiration, 395.
Apparent death, 1023.
Apyrenæmata, 228.
Aqueduct of Sylvius, 581.
Aqueous vapour, exhalation of, by lungs, 382.
——— importance of, in air, 393.
Arab race, 1000.
Arachnoid, structure of, 196.
Arago, Prof., on sensibility of retina, 759.
Arantius, on action of intercostals, 353.
Archencephala, 15.
Arciform fibres of medulla oblongata, 578.
Area presented by lungs for aeration of the blood, 369.
Area Germinativa, 919.
—— Opaca, 911, 919.
—— Pellucida, 911, 919.
—— Vascular, 920.
Areolar tissue, 39.
Arloin and Tripier, on inhibition of heart's action, 290 *note*, 294 *note*.
Arndt, M., on ganglia of sympathetic, 847; on cerebral convolutions, 659 *note;* on structure and termination of nerves, 526 *note*.
Arnold, M., on secretion of bile, 167; on heart sounds, 284 *note* ; on supra-renal bodies, 212; on erectile tissue, 340; on regeneration of corneal epithelium, 427; on sympathetic nerves, 847; on ganglion cells, 528; on muscle, 783; on emigration of leucocytes, 332.
Arnott, Dr., on stammering, 844 *note*, 845.
Arnstein, on action of Calabar bean on heart, 298 *note*.
Arrest of development, 398.
Arrow poison of Borneo, action of, on heart, 298 *note*.
Arsenic, in blood, 256; action of, on heart, 298 *note*.
Arseniuretted hydrogen, action of, on blood, 384.
Arterial blood, differential characters of, 258–261; cause of colour of, 259; effects of absence of, on muscular contraction, 275, 808.
——— system, first development of, 920; subsequent changes in, 927.
Arteries, movement of blood in, 304; properties of coats of, 305; irritability of, 305; contractility, 306; influence of chemical and other stimuli upon, 306; influence of nerves upon, 307; elasticity of, 305; pulsation of, 311; influence of nervous system on, 852; lateral pressure of blood in, 318; rate of movement of blood in, 323; development of, 921.
Arterin, 235.
Arthritic diathesis, 100.
Articular cartilage, 45.
Articulate Sounds, production of, 839, 843; vowels, 839–842; consonants, 842.
Artificial glottis, 834.
Aryan race, 998.
Arytenoid Cartilages, 828; movements of, 828.
Asp, on vaso-motor centres, 308; on structure of liver, 436, 437, 439.
Asparagin in urine, 479.
Asparaginic Acid, 163, 171, 176.
Asphyxia, effects of temperature on production of, 392; nature of, 387; phenomena of, 389; death by, 387, 1031; gases contained in the blood in, 390 *note;* effect of, on muscular contraction, 803, 809.
——— cutaneous, 493, 509.
Assimilation, 191; by Absorbent system, 192; by Vascular glands, 218; performed by Liver, 456.
Associated movements, ideas, 1018.
Asthenia, death by, 1030.
Asthma, spasmodic contraction of bronchial tubes in, 384.
Astigmatism, 727.
Atavism, 903.
Atlantidæ, 1000.
Atlas, development of, 946.
Atmograph, 350.
Atrophy, 424, 857.
Atropin, action of, on heart, 293.
Attention, effect of, on acuteness of touch, 706; on taste, 714; on smell, 717; on vision, 758, 820; on hearing, 776.
Attention, expectant, production of movements by, 863; influence of, on organic functions, 853, 863.
Aubert and Förster, on lymphatic system, 197; on acuteness of vision, 733; on eccentric vision, 756.
Aubert and Kammler, MM., on cutaneous sensibility, 703.
Aubert and Roever, on inhibition of heart's action, 290 *note*; on vaso-motor centres, 309.
Aubert, Dr. H., on cutaneous respiration, 377, 495; on acuteness of vision, 734, 744, 750, 779.
Auditory ganglia, 579.
——— nerve, 628; thorn cells, 763; auditory cells, 763; membrana reticularis, 764; otolith mass, 764.
——— nerves, origin of, 64, 623, 763; functions of, 862; ultimate distribution of, 763; effects of section of, 628.
——— organ, see *Hearing*, organ of.
Auerbach, on lymphatic system, 193, 194; on structure of capillaries, 327; on contraction of muscle, 802; on segmentation of ova, 911; on movements of nucleoli, 35 *note*.
Auerbach's plexus, 126, 145.
Auricles, thickness of, 273; blood pressure in, 321.
Auspitz, on absorption of solid bodies, 185.
Australia, inhabitants of, 1010.
Automatic action of respiration, 356.
——— activity of spinal cord, 119, 357, 607–617; of sensory ganglia, 634,

644; of heart, 285, 286; secondarily automatic actions, 117, 636.
Avalanche effect, 551.
Axile bodies of tactile papillæ, 699.
Axis cylinder, 524, 525.
—— spinal, 565.
Axmann, on trophic nerves, 854.
Azygos veins, 928.

BABER, on cartilage, 45; on thyroid gland, 216, 217.
Babington, Dr., on buffy coat of blood, 251; on uræmia, 463.
Babuchin, Prof., on electrical apparatus of torpedo, 521; on olfactory nerves, 716.
Bachl, on respiration, 383.
Bacillus, action of, in fermentation, 66.
Back, Capt., on low temperature, 506.
Bacteria, action of, in fermentation, 66.
Bacterium lactis, 66, 971.
———— termo, 67.
Bacteroid bodies of blood in disease, 67.
Badoud, on innervation of heart, 297 *note;* on pressure of blood in pulmonary artery, 321.
Baer, Von, on development, 909 *note*, 933 *note.*
Bagge, Dr. on development of entozoa, 909 *note.*
Bailey, J., on the Cingalese, referred-to, 1003 *note.*
Baillarger, M., on relative weight of cerebrum, 664.
Bain, on artificial respiration, 390.
Baker, Sir George, on diet, 103.
Bakewell, Mr., on red corpuscles of Hindu, 266.
Balance of vital economy, 402–419; see *Vital Economy.*
Balbiani, on development of spermatozoa, 871 *note.*
Balfour, on development of blood-vessels, 923; on ovaries, 874 *note*, 885 *note.*
——— on development, 866 *note*, 918 *note.*
——— on segmentation of ova, 911.
——— on formation of blastoderm, 913 *note.*
——— on origin of mesoblast, 914 *note.*
——— on primitive streak and groove, 915 *note*, 916.
——— on development of heart, 918 *note.*
——— on development of urinary organs, 934 *note.*
——— on development of Müllerian duct, 936.
——— on primordial ova, 939.
——— on development of skeleton, 944 *note.*
——— on development of adrenals, 213.
Ballard, Dr. E., on tactile sensibility, 700 *note.*
Ballou, Dr., on suspended lactation, 970 *note.*
Balogh, on cells of villi, 181.
Baly, Dr., on mechanical excitation of olfactive and gustatory senses, 708; on corpus luteum, 884 *note.*
Banks, Dr. W. M., on homologies of different parts of the sexual apparatus, 942.
Banting, Mr., his mode of reducing obesity, 173, 409.
Baræsthesometer, 703.
Baragiola, on chorda tympani, 624 *note.*
Barclay, Capt., his power of sleep after exercise, 686.
Bardeleben, on structure of arteries, 305.
Bärensprung, on temperature of fœtus, 499; on trophic nerves, 855.
Bärisch, pressure of bile in duct, 167.
Barium, action of salts of, on heart, 298 *note.*
Barker, Dr., his case of short gestation, 900 *note.*
Barlow, Mr. F., on post-mortem movements in cholera patients, 809; on climacteric disease, 1027 *note.*
Barral, M., on excretion of carbonic acid, 378; on heat produced in body, 515; on elimination of nitrogen, 382.
Barry, Dr. Martin, on Graaffian follicle, 875 *note;* on number of ova, 877; on penetration of spermatozoa into ovum, 885 *note.*
Bartel, on uræmia, 463 *note.*
Bartholin, glands of, 880 *note.*
Bartholini, glands of, 941.
Bartholinus, on intercostal muscles, 352.
Basal ganglia, 617–618.
Basch, Von, on intestinal movements, 128; on influence of oxygenated blood on muscle, 793 *note;* on action of nicotin on heart, 298 *note;* on nerves of uterus, 894.
Basham, on uræmia, 464.
Basis, 631.
Basque race, 999.
Bastian, Dr., on migration of white corpuscles, 331; on specific gravity of brain, 665; on perceptive centres, 679; on spontaneous generation, 865 *note:* on fermentation, 66.
Bataille, M., on phonation, 837 *note.*
Baths, influence of, on animal heat, 508.
Batrachia, respiration in, 377.
Baudot, M., on effects of disease on animal heat, 511; on stimulation of vagus, 297.
Bauer, on absorption of albumin in rectum, 188.
Baumann, on phenol, 89.
Baumgarten, on optic chiasma, 622.
Baxt, M., on rapidity of motor impulses, 553 *note.*
Baxter, Mr., on disturbance of electric equilibrium in organic processes, 521; on absolute force of muscle, 822.
Bayly, on special sensations, 697.
Beale, Prof. L., on constitution and development of cells, 37; on composition of thymus, 216; on cardio-motor ganglia, 285 *note;* on nerves of capillaries, 327; on structure of liver, 434, 436; on kidney, 461; on structure of nerves, 437, 526; on nerve-endings in skin, 699 *note;* in tongue, 710 *note;* in muscle, 787; on sympathetic ganglia, 528, 847.
Beale, on contractility of capillaries, 328.
Beard, Dr., on excitation of cerebrum, 747.

Beats, 762.
Beau and Maissiat, MM., on respiratory muscles, 352.
Beaumont, Dr., on sense of satiety, 101; on movements of stomach, 122; on secretion of gastric juice, 151.
Beaunis, on colouring matter of adrenals, 213; on cerebral localization, 676 *note;* on depressor nerve, 310.
Béchamp, on urinary ferment, 478; on starch, 84.
Beck, J. R., on function of uterus in impregnation, 880 *note;* on superfœtation, 902 *note.*
Becker, Von, on visual accommodation, 722.
Béclard, M., on quantity of food required, 96, 97; on composition of blood of portal vein, 262; on erectile tissue, 340; on total heat produced by body, 515.
Becquerel and Breschet, MM., on cutaneous respiration, 512.
Becquerel and Rodier, on composition of blood, 254; ditto in disease, 265, 268.
Becquerel and Vernois, 974.
Becquerel, on electricity, 521 *note.*
Beddoe, on stature and bulk of Man, 965 *note.*
Beef-tea, composition of, 98.
Bees, formation of fat by, 413.
Beetroot, composition of, 97.
Beigel, on menstruation in relation to excretion of urea, 471.
Beil, on corpuscula tactûs, 699 *note.*
Belajeff, M., on lymphatic system, 193; on lymphatics of heart, 275; on respiration of oxygen, 385.
Belfield-Lefèvre, M., on tactile sensibility, 701 *note.*
Bell, Mr. T., on secretion of serpent poison after death, 1029; on Australian dingo, 992; on medulla, 584.
Bell, Sir C., on guiding sensations, 637; on motor nerves of respiration, 363; on respiratory movements, 357; on distinct functions of anterior and posterior roots of spinal nerves, 541; on cranial nerves, 544; on hypoglossal nerve, 594.
Bellini, tubes of, 457.
Bellouard, on optic tract, 720.
Beltrami, on origin of fibrin, 246 *note.*
Bement, Mr., his cases of protracted gestation, 901.
Bemiss, Dr., on hereditary mental disease, 904 *note.*
Benecke, on regeneration of nerves, 528 *note.*
Beneden, Van, theory of function of blastoderm, 913 *note;* origin of mesoblast, 915; on development, 875 *note,* 908 *note,* 910 *note;* on segmentation of ova, 911.
Benedikt, M., on effects of division of the sympathetic, 850.
Beneke, on cholesterin, 88.
Benzoic acid, 79; in kidneys, 477; in sweat, 491.
Bennett, Prof. J. H., on pepsin, 153; on production of blood-corpuscles in ductless glands, 219; on leucocythæmia, 267; on bile, 446.
Bérard, on venous circulation, 335.
Berber race, 1001.
Berg, on respiration, 374.
Berger and Delaroche, MM., on experiments on animal heat, 508.
Bergeron, on heart, 297 *note.*
Bergmann, Dr., on respiration in nitrogen, 379; on acuteness of vision, 734.
Bernard, M. Claude, on ferments, 69; on hydrocarbonaceous compounds, 83; on glycogen, 450; on gastric juice, 160; on movements of intestines, 123; on saliva, 134; on gastric digestion, 145, 146; on composition of gastric juice, 152; on pancreatic juice, 162; on bile, 168; on intestinal digestion, 171; on quantity of blood, 222; on temperature of blood, 224; on amylolytic liver ferment, 451; on relation of sympathetics to formation of glycogen, 453; on urea in blood, 465; on duration of life of blood-corpuscles, 241; on gases of blood, 262; on colour of blood, 223, 261; on formation of fibrin, 246; on gravitation of red corpuscles of blood during life, 243; on irritability of endocardium, 276, 287; on inhibition of heart's action, 297 *note;* his differential thermometer, 319, 320; his cardiometer, 320; on respiration of carbonic oxide, 385; on asphyxia, 393; on hepatic circulation, 444; on glycogeny, 447, 450; on albuminuria, 462; on gases of urine, 483; on death by heat, 509; on animal heat, 503, 509 *note,* 515, 516; on spinal accessory, 593; on relation of facial nerve to sense of taste, 624; on curare, 298 *note;* on sympathetic nerve, 155, 848, 856; on section of sympathetic, 516, 850; on dilating nerves, 852; on contraction of pupil, 736; on circulation in muscle, 802; action of drugs on muscle, 803; on milk, 972.
Bernhardt, temperature of blood in heart, 224 *note;* on depressor nerve, 309; on inhibition of heart's action, 290 *note.*
Bernstein, on state of thorax before birth, 362.
Bernstein, M., on rapidity of muscular contraction, 799; on Calabar bean, 727 *note.*
Bert, on gases of blood, 14, 259, 260; on respiration of tissues, 342; on contractility of lungs, 347; on respiratory movements, 351; on respiration of oxygen, 342, 350, 376, 385; on asphyxia by drowning, 388.
Bertholet, on testis ferment, 69.
Berzelius, his analysis of urine, 468 *note;* on acid of gastric juice, 146.
Besanez, v. Gorup-, see *Gorup-Besanez.*
Bever, M.K., on vaso-motor centre, 295 *note,* 308.
Bezold, Von A. M., on sympathetic, 848 *note;* on coronary arteries, 276 *note;* on the innervation of the heart, 290 *note,* 295 *note;* on the action of curare on heart, 298 *note;* on the action of atropin on

heart, 293, 298 *note;* on vaso-motor centre, 308; on influence of oxygen on muscle, 803; on action of veratria on muscle, 802, 803; on electrotonus, 560; on trophic nerves, 858; on contraction of muscle, 799 *note.*
Bichât, on closure of pupil, 736.
Bidder, on movements of deglutition, 118; on cardio-motor ganglia, 285 *note,* 286; on action of curare on vagus, 298 *note;* on elimination of carbonic acid, 371; on kidney, 456 *note;* on union of motor with sensory nerves, 544; on sympathetic of cat, 848 *note;* on spinal cord, 570; on trophic nerves, 856 *note.*
Bidder and Schmidt, on quantity of lymph, 200; on excretion of bile in relation to food, 166, 174, 446; on nutrition, 402 *note,* 407; on effects of fat on bile, 445.
Biesiadecki, Prof., on organisms in blood, 269 *note;* on liver, 439; on optic chiasma, 623; on corpuscula tactûs, 699 *note.*
Bile, test for, 82; secretion of, by hepatic cells, 433, 437, 444; excrementitious character of, 443–444; essentially formed from products of disintegration, in and by the liver itself, 444; but partly from newly absorbed materials, 445; its relation to fatty and albuminous compounds, 445; influence of nervous system on, 446; vicarious secretion of, 432; composition of, 440, 446; character of, 440; quantity of, 166, 403; its uses in digestion, 164; aids the absorption of fat, 165; its re-absorption from intestine, 174, 446; spectrum of, 442; its presence in fæces, 445; and in other tissues, 433; bile acids, 441; pressure under which it is secreted, 440; presence of, in urine, 469; gases of, 440; colouring matter of, 440; index of refraction for light, 443; effect of blood supply on secretion of, 443; spectrum of Pettenkofer's test for, 443; first appearance of, in gall bladder, 445; effect of drugs upon flow of, 446, 447.
Bile ferment, 69.
Bile-pigment, 441.
Biliary cells, 438; biliary fat, 88.
Bilifulvin, 442.
Bilifuscin, 442.
Bilihumin, 442.
Bilineurin, 81.
Biliprasin, 442.
Bilirubin, 174, 441, 444.
Biliverdin, 174, 441, 442, 444.
Billing, Dr., on sounds of heart, 284 *note.*
Billroth, Dr. T., on spleen, 207; on heat developed in tetanus, 798.
Binocular vision, 739 *et seq.*
Bird, Dr. Golding, on action of acetates on urine, 487; on action of diuretics, 488; on action of oxalates, 484.
Birkett, Mr., on the anatomy of the breast, 967.
Birkner, on effect of withdrawal of water from nerves, 550.
Birsch-Hirschfeld, on organisms in blood, 269 *note.*
Bischoff, Prof., on penetration of ovum by spermatozoa, 884; on embryonic development of mammals, 909 *note;* on rotation of yolk, 914.
Bischoff and Voit, MM., on gelatin diet, 95; on general nutrition, 402, 407; amount of bile acids in fæces, 445.
Bischoff, M., on inorganic compounds, 92; on urine, 470 *note;* on impregnation, 884, 886.
Bishop, Mr., on motion, 814 *note;* on physiology of voice, 837; on stammering, 844 *note.*
Bistrow, on milk, 978 *note.*
Biuret-reaction, 149.
Bizio, M., on glycogen, 450.
Bizot, M., on relative size of right and left ventricles, 273.
Bizzozero, on cells of bone, 50; on lymphatic glands, referred-to, 195; on myeloplaxes, 218; on spermatozoa, 870 *note,* 871 *note;* on fatty degeneration of muscle, 420.
Bladder, urinary structure of, 488.
Blagden, Dr., experiments on animal heat, 508.
Blainville, on coagulation of blood in vessels, 248.
Blake, Prof., on quantity of blood, 222 *note;* on action of various poisons on heart, 298 *note;* on rapidity of circulation, 299; on animal heat, 500; on limits of audible sounds, 760 *note.*
Blane, Sir G., on reflex acts, 606.
Blastoderm, 908, 911; formation of, 913; theory of formation of, 913 *note;* formation of the trilaminate, or primary, 914; growth of, 915; formation of quadrilaminate or secondary, 917 *note.*
Blau, on excitation of chorda tympani, 708 *note.*
Blind persons, improvement of hearing in, 776; movements of eyes in, 820.
Blöbaum, on action of atropin on heart, 298 *note;* on action of oxygenated blood on muscle, 793 *note.*
Blomfield, J. E., on development of spermatozoa, 871 *note.*
Blondlot, on gastric juice, 146, 152; on the bile, 166 *note.*
Blondeau, on formation of fat, 414.
Blood, general character and purposes of, 220; quantity of, 221, 223; urea in, 479; temperature of, in various parts, 224; colour of, 223; specific heat of, 224; microscopical characters of, 225; crystals of, 236; spectrum analysis of, 240; pneumatology of, 258, 381; (see *Carbonic Acid*); in urine, 469; distribution of, 223, 337; refractive power of, 224.
Coagulation of Blood, 241–250; influence of fibrin upon, 243; influence of red corpuscles upon, 242, 246; influence of white corpuscles upon, 246; coagulation in inflammation, 250; effect of pepsin upon, 251; effect of alkaloids upon, 251; occasional deficiency of, 249;

retardation of, 249 ; effect of external influences on, 242, 249 ; influence of rest, 250 ; influence of temperature, 242, 248, 250 ; effect of neutral salts, 243, 251 ; effect of exclusion of atmosphere, 251 ; influence of depressed vitality or death of vessels, 248 ; influence of admixture of dead matter, 248 ; formation of buffy coat in, 243 ; effect of irrespirable gases on, 250.

Composition of, in Health, 254 ; extraction of, 254 ; ferment of, 255 ; salts of, 255 ; modification of, by age, 256 ; by sex, 256 ; by food and drink, 257 ; by loss of blood, 258 ; differences of arterial and venous, 261; peculiarities of portal blood, 249, 447 ; of mesenteric blood, 263; of splenic blood, 219, 246 ; of hepatic vein, 249, 480 ; of renal vein, 249, 469.

Composition of, in Disease, 242 ; increase of fibrin, 247, 265 ; diminution of fibrin, 247, 266 ; increase of red corpuscles, 266; diminution of red corpuscles, 266 ; increase of colourless corpuscles, 267; diminution of albumin, 267; increase of fatty matter, 268 ; altered proportion of salts, 268 ; of water, 268 ; presence of poisons in, 250, 809; presence of organisms in, 269 *note*.

Corpuscles of, Red ; form, size, and aspect of, 225, 228 ; number of, 225 ; composition of, 235, 253 ; influence of reagents on, 227, 241, 454 ; tendency to aggregation of, 230 ; production and disintegration of, 234 ; embryonic development of, 251, 924 ; subsequent development of, from lymph corpuscles, 252 ; change of colour in, by respiration, 259 ; their uses, 380 ; variations in amount of, in disease, 266 ; mutual attraction of, in coagulation, 243 ; adhesion of, to walls of vessels, 355 ; duration of existence of 241.

Corpuscles of, Colourless ; form, size, and aspect of, 231 ; peculiar movements of, in capillaries, 231 ; structure of, 231 ; action of reagents on, 232; numerical proportion of, to red, 219, 233 ; their variations in number, 239 ; multiplication of, in disease, 267 ; influence of, upon coagulation, 246.

Distribution of, 223, 337.

Pressure of, against arteries, 319 ; in hepatic veins and in vena portæ, 435.

Properties of, Physical, 223.

Properties of, Vital, 241 ; self-maintaining power of, 252 ; uses of fibrin of, 248; uses of corpuscles of, 231, 246 ; purification of, by respiratory processes, 369 ; by excretion of bile, 444 ; by excretion of urine, 468 ; by excretion of skin, 490 ; composition of, determines modes of nutrition, 401 ; electrical conditions of, 521.

Rate of Propulsion of, by heart, 299 ; rate of movement of, through arteries, 317 ; through capillaries, 329 ; through veins, 336.

Blood ferment, 69.

Blood pressure in auricles and ventricles, 321.

Blood-relations, effects of marriage of, 904, 908.

Blood-vessels, vaso-motor nerves of, 308, 849 ; vasomotor centre of, 309 ; absorption by, from alimentary canal, 182–184 ; contractility of, 305 ; dilatation of, 852 ; development of, 920, 923 ; from body in general, 188 ; (see *Arteries, Capillaries, Veins*).

Blumenbach, Prof., on zoological position of man, 15 ; on races of mankind, 985.

Blundell, on inanition, 113.

Bobrik, on effects of acids on heart, 287.

Bochdalek, on ciliated epithelium on tongue, 38 *note*.

Bochefontaine, on cerebral centres, 676.

Bock, on cells of liver, 438 *note*.

Böcker, Dr., on influence of tea, 109, 302, 486 ; on influence of diet on urine, 465, 471 ; on influence of alcohol, 487.

Boddart, v., on effects of section of vagus, 365.

Bödecker, on the composition of milk, 974.

Boéchat, on thyroid gland, 216.

Boehm, on inhibition of heart's action, 290 *note ;* on action of poisons on heart, 293 *note*, 298 *note*.

Boehm and Hoffmann on hæmaturia produced by injection of glycogen, 454.

Boerhaave, on intercostal muscles, 352 ; on rut, 878.

Bogoljubow, on gases of bile, 440.

Bogomoloff, on pigments of bile and urine, 477 ; on reaction of milk, 970.

Boileau, Lieut., on apparent death, 1032 *note ;* on influence of climate on temperature, 499 *note*.

Boileau-Castelnau, M., on insufficient diet at the Maison Centrale of Nîsmes, 114.

Bois-Reymond, M. Du, on electrical disturbance in organic processes, 521 *note :* his law of nerve excitation, 549 ; on electrical phenomena in nerves, 554, 561 ; on electrotonus, 556, 557, 560 *note*, 564 *note ;* on muscular current, 522, 796 ; on muscle, 790 *note*.

Boismont, Brierre de, on menstruation, 877 *note*.

Bókay, on nuclein, 73 ; on lecithin, 82 ; on pancreas, 161.

Boll, on structure of tendon, 41 ; on visual purple, 730 *note*, 731 *note*.

Bone, structure and growth of, 46.

Bones, composition of fossil, 50.

Bonnar, on limits of gestation, 902 *note*.

Booker, on respiration-regulating centre, 356 ; on respiration in frog, 362.

Borax, effect of, on fermentation, 68.

Borelli, on intercostal muscles, 352.

Born, on ovaries, 874 *note*.

Borneo arrow poison, action on heart, 298 *note.*
Borsarelli, on amount of phosphorus in brain, 530.
Böttcher, on blood, 226 *note.* 227; on blood-crystals, 235, 239; on lesions of semi-circular canals, 628; on spermatozoa, 869.
Botschetshkaroff, on effects of division of splenic nerves, 210.
Boucher de Perthes, M., on flint implements, 981.
Boudin, M., on hereditary disease, 904 *note.*
Bouillaud, M., on auricles of heart, 273, 274; on cerebellum, 647 *note.*
Boulton, on the growth of children, 963.
Bounafont, on membrana tympani, 769.
Bourdon, M., on voluntary arrest of respiration, 357 *note.*
Bourgery, on weight of brain, 664.
Boussingault, M., on respiration, 370; on excretion of nitrogen, 381; on fæces, 406; on formation of fat, 413.
Boutigny, M. De, on bad conductibility of aqueous vapour, 507 *note.*
Bowditch, on the force of ciliary movement, 781; on heart, 276, 287.
Bowman, Mr., on structure of liver, 434; on fatty liver, 438; on kidney, 456 *note,* 457–458; on ciliary muscle, 722; on retina, 728; on muscle, 785.
Boyer, on relative capacity of cardiac ventricles, 273.
Bozzi, M., on spermatozoa, 872 *note.*
Brachycephali, 987, 997.
Braconnot, on air of large towns, 393.
Bradford, on numeration of blood corpuscles, 226, 233.
Braid, Mr., on hypnotism, 686, 692, 1032 *note;* on influence of nervous system on the organic functions, 863.
Braidwood, Mr., on development of muscle, 791; on arrow poison, 298 *note.*
Brain of Man, compared with that of apes, 27; arrangement of convolutions of, 28, 29, 658; concussion of, 806; development of, 953; weight of, in relation to stature, 664 *note;* weight of, in relation to race, 664 *note;* presence of glycogen in, 450; weight of, 664; (see *Cerebrum, Cerebellum,* and *Sensory Ganglia*).
Branchial arhes, 924, 928.
Brandt, on movements of nucleoli, 35 *note.*
Braune, case of artificial anus, 130.
Bread, bad economy of exclusive diet of, 96.
Breeds of animals, origination of new, 993.
Brémond, on cutaneous absorption, 190.
Breschet and Becquerel on cutaneous respiration, 512.
Brettauer and Steinach, MM., on epithelial cells of villi, 181.
Breuer, on respiration, 358; on kinetic theory of hearing, 774; on effects of stimulating laryngeal nerves, 361.
Brewster, Sir D., on spectrum analysis of blood, 239; on law of visible direction, 738 *note,* 755.
Breymann, on vaso-motor centre, 308.
Bridgeman, Laura, case of, 31.
Brieger, on phenol, 89.
Bright, Dr., on fatty discharges, 162.
Bright's disease of kidney, 461.
Brinton, Dr. W., on peristalsis, 122.
Broadbent, Dr., on inorganic constituents of body, 91; on sounds of heart, 284; on lesions of optic thalami and corpora striata, 633; on paralysis, 674; on aphasia, 679; on co-ordination of reflex movements 615.
Broca, M. P., on the primates, 46 *note;* on aphasia, 678; on antiquity of man, 981 *note;* on colour of man, 984; on anthropology, 987 *note.*
Brodie, Sir B., on tobacco, 109; on action of nervous system on animal heat, 503.
Bromide of potassium, action of, on heart, 298 *note.*
Bronchial tubes, structure of, 344; contractility of, 374; vessels, 373.
Brondgeest, M., pansphygmograph, 350; on action of chloroform on heart, 298 *note.*
Bronzing of the skin, 217.
Brooke, Mr. C., on otic ganglion, 770; on conduction of sound, 772 *note.*
Brown, Crichton, on cerebral localization, 676 *note.*
Brown, Dr. Crum, on irritability of muscle, 803; on section of semi-circular canals, 773 *note;* on kinetic theory of hearing, 774.
Brown-Séquard, on adrenals, 212; on formation of fibrin, 246; on vaso-motor centres, 309; on respiratory nerve-centres, 363, 610; on asphyxia, 388; on renal circulation, 460; on animal heat, 504 *note,* 529; on recurrent sensibility of anterior roots of spinal nerves, 541; on restoration of function of spinal cord after division, 596; on functions of posterior columns, 597; on course of fibres in spinal cord, 599–602; on effects of section of one lateral half of spinal cord, 609; on medulla oblongata, 611; on corpora restiformia, 612; on muscular tension, 616; on section of optic tract, 623; on lesions of the thalami, 630; on functions of mesocephalon, 632; on cerebellum 746 *note,* 748, 750 *note;* on channels for various sensations, 704; on action of light on iris, 736, 737; on closure of pupil, 736; on cerebrum, 677; on restoration of muscular irritability, 808, 809; on effects of sympathetic, 849, 857; on albuminous urine, 408 *note;* on rhythmical movements of muscles, 805 *note;* on lesions of kidneys, 467 *note;* on normal temperature, 498 *note.*
Brownian movements, 39, 52, 780.
Brozeit, on quantity of blood, 223.
Bruch, Prof., on absorption of fat, 184.
Brücke, on pigment cells, 39; on reabsorption of pepsin, 148; on colour of blood, 223; on red corpuscles of blood, 227; on gly-

cogen, 449; on fæces, 173; on Peyerian glands, 181; on muscle, 785, 789; on cause of heart systole, 277 *note;* on structure of red corpuscles, 227; on emulsification of fat, 162; pseudo-fibrin, 62; extract of pepsin, 68; test for glycogen, 84.
Brunn, v., on development of adrenals, 213.
Brunnen, on ossicula auditûs, 771 *note.*
Brunner, on glands of intestines, 168; on composition of milk, 974.
Brunton, Dr., on albumins, 69; on splanchnics, 128; on composition of the nucleus of the white corpuscles, 232; on action of heat on heart, 288 *note*, 290; on action of atropin on heart, 293; on digitalis, 298 *note*, 488; on influence of position on pulse, 301; on rhythmical movements of vessels, 307; on vaso-motor nerves, 309; on glycogen, 450; on effects of stimulating corpora quadrigemina, 627; on acids of urine, 484; on secretion of urine, 466.
Buchanan, Dr., on coagulation of blood, 242 *note;* on left-handedness, 817 *note;* on force of the heart, 285, 417.
Buchheim, on action of drugs on muscle, 802 *note;* on action of curare on heart, 298 *note.*
Buck, Dr., on ossicula auditûs, 770, 771 *note.*
Bucquoy, on effects of atmospheric pressure on heart, 302 *note.*
Budd, Dr. G., on liver, 445.
Budd, Dr. W., on hypoglossal, 594; on paraplegia, 607; on epilepsy, 614.
Budge, Prof. J., on cartilage, 45; on deglutition, 118; on inhibitory nerves, 290 *note;* on movements of intestines, 127; on gastric juice, 155; on irritability of heart, 276; on action of poisons on heart, 298 *note;* on influence of various circumstances on pulse, 302; on dynamics of circulation, 317; on intercostal muscles, 352; on lymphatics of liver capsule, 439 *note;* on excitability of nerves, 551; on ciliary ganglion, 586 *note;* on sympathetic centre of urinary bladder, 488; on seasonal changes of temperature, 503; on genito-spinal centre, 609; on effects of stimulating corpora quadrigemina, 627; on nerve endings, 699 *note;* on stimulation of muscle, 804; on vaso-motor fibres, 852.
Budge and Waller, Drs., on influence of nerves on pupil, 735 *note;* on genito-spinal centre, 609.
Buffy coat of blood, 243.
Buisson, action of poisons on muscle, 803.
Bulbus arteriosus, 927; aortæ, 923.
Bulgak, on origin of splenic nerves, 210; on corpuscles of splenic blood, 219.
Bunge, on hippuric acid, 79.
Burdach, on quantity of blood, 222; on formation of fat, 414; on vicarious secretion of urine, 431, 432; on cerebellum, 654; on influence of nerves on secretion, 861; column of, 566, 571, 597.
Burkart, M., on effects of stimulation of vagi, 360; on laryngeal nerves, 361, 364.
Burnett, on ossicula auditûs, 771 *note.*
Burrows, Sir G., on intracranial blood circulation, 339 *note.*
Busch, on cessation of gastric movements during sleep, 124; case of injury of intestine, 130; on absorption, 186.
Bushmen of Southern Africa, 1006.
Busk, Mr. G., on alteration of blood in scurvy, 265; on muscle, 785 *note.*
Busse, on elimination of carbonic acid, 373.
Butchers' meat, composition of, 97.
Bütschli, on segmentation of ova, 911 *note.*
Büttner, on trophic nerves, 858.
Butyric acid fermentation, 66.
Butyric acid, 89.
Byasson, M., on excretion of urea, 474; of uric acid, 475; of phosphates, 482 *note;* of chlorides, 483.

CADAVERIC rigidity, 809.
Cadiot, on effects of consanguineous marriages, 904 *note.*
Caffein, action of, on heart, 298 *note.*
Calabar bean, action of, on heart, 298 *note;* effect of solution of, on eye, 727.
Calamus scriptorius, 578.
Calcutta, Black Hole of, 391.
Caldani, on optic chiasma, 623.
Callender, on development of thyroid gland, 216; on development of facial bones, 951.
Calliburcés on effect of temperature on heart, 288 *note*, 302.
Calorifying power, sources of (see *Heat*), 514, 517.
Calory, definition of, 514 *note.*
Camerer, on intensity of gustatory sensations, 712.
Campbell and Heynsius, on origin of urinary pigment, 477.
Camper, angle of, 987.
Canaliculi of bone, 47.
Cane sugar, 84; effects of, on digestion, 150.
Capacity for progress, a characteristic of man, 32.
Capillaries, structure of, 326; diameter of, 327; arrangement of, 329; rate of movement of blood through, 329; its variations in, 330; its independence of heart's action in, 330; its regulation in, by conditions operating in capillaries themselves, 331; influence of nervous system on, 849; of nervous supply to, 523; of lungs, extent of, 347.
Cappie, on cranial circulation, 339; on causation of sleep, 681 *note.*
Caproic acid, 89.
Capronic acid, 89.
Caprylic acid, 89.
Caput cornu of the grey substance of the spinal cord, structure of, 567.
Carbolic acid in urine, 478.
Carbon, amount of, excreted daily, 377; quantity of, required in food, 402.

Carbonic Acid in blood, 260; sources of production of, in system, 342; action of, on heart, 298 *note;* circumstances affecting quantity generated, 369, 824; seat of origin of, 379; extraction of, from skin, 377; elimination of, in atmosphere of nitrogen or hydrogen, 378, 379; effects of respiration of, 359, 385, 393; elimination of during fasting, 378; average proportion in pure air, 368; in expired air, 369; in air of towns, 393; its ordinary proportion in urine, 484; influence of inanition on excretion of, 371; sources of, 379; various circumstances affecting quantity of, 369; its presence in blood, 258; in expired air, 369; in sweat, 547, 551; consequences of its non-elimination, 463.
Carbonic oxide, action of, on heart, 298 *note;* effects of, on blood, 241; effects of respiration of, 359, 385, 393.
Carburetted hydrogen, elimination of, by lungs, 369.
Cardiac plexus of sympathetic, 274, 846; centres, 611.
Cardiac sphincter of stomach, 123.
Cardiograph, 282.
Carlet, on walking, 814.
Carnin, 73.
Carnivorous animals, gastric juice of, 150.
Carnochan, on trophic nerves, 857.
Carroval, action of poison of, on heart, 297.
Carter, T. A., on lymphatic system, 193.
Carter, Vandyke, on trophic nerves, 855, 866.
Carter, on urinary pigment, 478.
Cartilage, structure and growth of, 44.
Carville and Duret, on effect of lesions of corpora striata, 631.
Carville, on Inée, 298 *note.*
Casein of milk, 62; composition of, 59; digestion of, 148, 971, 973; ferment, 977.
Casey, on diurnal variations in temperature, 500.
Caspar, on diseases of viability, 1024 *note.*
Castell, effect upon heart of its immersion in carbonic acid, 276 *note.*
Catamenia, 878–880 (see *Menstruation*).
Caton, on emigration of leucocytes, 331.
Caucasian race, 998; variety of colour in, 985.
Caudate nucleus, 630.
Cayrade, on effects of stimulating corpora quadrigemina, 627 *note.*
Cell wall, 34.
Cells, encased, 33; structure and mode of increase of, 34; rhythmical movements in, 780; pavement or tessellated, 36; columnar or cylindrical, 37; spheroidal, 38; chalice, cup, or goblet, 39, 344; pigment, 39; cartilage, 45; nerve, 527; ciliated, 38, 47, 781; influence of reagents, on ciliated cells, 781.
Cellulose, 83, 447.
Celtic race, 999.
Cementum of teeth, 55.
Centres of respiratory movements, 356.
Centrifugal nerves, (see *Efferent nerves*).
Centripetal nerves, (see *Afferent nerves*).
Cephalic nerves, general character and relations of, 577–596; homologies of, 595.
Cephalic index, 987.
Ceradini, on valves of heart, 280 *note;* on intercostal muscles, 353.
Cerebellum, peculiar to vertebrata, 537, 644; structure and relations of, 645, 663, 873; relative development of, in different animals, 537; results of experiments on, 646, pathological phenomena of, 649; functions of, 646–656; race characteristics, 662; weight of, 664; weight of, in various animals, 653; alleged sexual function of, 652–656.
Cerebral centres, 670–677.
Cerebrin, 72, 529.
Cerebro-spinal fluid, 665.
Cerebro-Spinal System, see *Nervous System, Cerebellum, Cerebrum, Cord, Crura Cerebri, Medulla Oblongata, Sensory Ganglia, Spinal Cord.*
Cerebrum, comparative anatomy of, 537; peculiar to vertebrata, 537, 657, 729; arrangement of convolutions of, 27–30, 658; structure of, 659; its relative size in different animals, 664, 666; its vast predominance in man, 664; its anatomical structure, 658–664; its weight, 664; its supply of blood, 665; circulation in, during sleep, 682; lymphatics of, 665 *note;* development of, 952; projection system of Meynert, 661; specific gravity of, 665.
Functions of, 538, 539, 626, 666 *et seqq.*; centres of, 670–677; its relation to intelligence as contrasted with instinct, 667, 677; electrical excitability of hemispheres, 670; latent period for stimulation of, 673; relation of, to speech, 678; intellectual and emotional functions of, 680; Hitzig's experiments on, 670; Ferrier's experiments on, 671; motor centres in, 673; effects of its removal, 676; information deducible from its pathology, 677; functions of, arguments deduced from comparative anatomy, 666–670; functions of, arguments deduced from experiment, 670; its functional connection with sensory ganglia, 572; sensory localization, 675 *note;* irradiation in, 605; effects of removing, 626.
Cervix cornu of the grey substance of the spinal cord, 567.
Cetacea, provision for storage of oxygen in, 387.
Chabert the Fire King, 507.
Chalazæ, 910.
Chalice-cells of lungs, 344.
Chalvet, on blood in scurvy, 265, 268.
Champollion, on antiquity of man, 981 *note.*
Chandelon, on glycogen in muscle, 454; 790 *note.*
Chantrey's workmen, 507.

Charcot, on trophic fibres, 855.
Chatin and Bouvier, on blood in scurvy, 265.
Chaumont, de, on diet, 102.
Chaussier, on weight of infants at birth, 992.
Chauveau, on expiratory murmur, 354; on rate of movement of blood, 324; on sugar in blood of hare, 448; on electrical stimulation of nerve, 549, 589; on glosso-pharyngeal, 590; on heart, 282.
Chemical composition of the body, 58.
Chenocholic acid, 441 *note*.
Chenu, on inanition, 115.
Cheselden, on sense of vision, 737, 741.
Chevallier, on milk of sheep, 976.
Chevreul, M., on gastric juice, 146; on colours, 754 *note*; on composition of beef-tea, 98.
Cheyne, G., on apparent death, 1032.
Chickens, time required to produce asphyxia in, 388.
Childhood, characteristics of, 1016, 1017; diseases of, 1017, 1024.
Children, physical development of, 963.
Childs, Dr., on consanguineous marriages, 904 *note*.
Chimpanzee, comparison of, with man, 17.
Chinese, 1002.
Chirac, on vicarious secretion of urine, 432.
Chittenden, on glycogen in scallop, 450.
Chlorine gas, effects of respiration of, 359.
Chloroform, action of, on heart, 298 *note*.
Chlorosis, state of blood in, 266; treatment of, 266 *note*.
Cholalic acid, 81, 441; in fæces, 445.
Cholepyrrhin, 442 *note*.
Cholera, state of blood in, 266; influence of imperfect respiration in developing, 394; cause of spasms in, 550; movements after death from, 809.
Cholesteræmia, 89.
Cholesterin, 88; in fæces, 173, 174; in bile, 442; in blood, 444; in nerve, 529.
Cholic acid, 81, 441.
Cholin, 81.
Choloidinic acid, 441 *note*.
Cholophæin, 442 *note*.
Chondrin, 71.
Chondroblasts, 45.
Chondroglycose, 71.
Chorda dorsalis, 944, 1024 (see *Notochord*).
Chorda tympani, 589, 624; dilator fibres in, 310; nerve, 586, 708.
Chordæ vocales, necessity for separation of, 832; method of measuring their action, 835; regulation of their tension, 826–829.
Chorion, formation of, 886, 889, 919; frondosum, 886.
Chossat, his experiments on inanition, 111, 510, 511; on animal heat, 503 *note*.
Chouppe, on vomiting, 125.
Christison, Sir J., on the blood serum in disease, 267; on limits of gestation, 899 *note*.
Chromatic aberration, 719.
Chromatoptometry, 749.
Chromoblasts, 39.
Chromophane, 731.
Chyle, composition of, 199; microscopic characters of, 202; assimilation of, 203; movement of, 204; development of red-corpuscles from, 252.
Chyme, movement of, 125; formation of, by digestive process, 158.
Chrzonszczewsky, on capillaries, 327; on lungs, 346; on cutaneous absorption, 191; on terminal bile ducts, 437.
Ciaccio, on nerve endings, 699 *note*.
Cicatricula, 911.
Ciliary cells, 38, 47, 781.
——— ganglion, 586.
——— movement, 781; force of, 781; influence of reagents on, 781.
——— muscle, function of, 723.
Ciliated cells, 38, 47, 781; distribution of, 38; in digestive tract, 38 *note*.
Cilio-spinal centre, 609, 848.
Cinchonin, action of, on heart, 298 *note*.
Circulating albumin, 404.
Circulation, 270; general plan of, 270, 271; action of heart in, 270–304 (see *Heart*); action of arteries in, 270 (see *Arteries*); action of capillaries in, 326 (see *Capillaries*); action of veins in, 333 (see *Veins*); account of, 279; rapidity of, 299.
Peculiarity of, in cranium, 338; in liver, 271, 338; in lungs, 383; in erectile tissues, 339; in kidneys, 338, 459; in brain during sleep, 682.
In fœtus, early type of, 271 *note*, 918; change in plan of, 927; plan of, in mature fœtus, 930.
In plants, 272.
Cisoff, on smell, 716 *note*.
Civilization, influence of, on form of skull, 990; on body in general, 991.
Clarke, Dr. J. Lockhart, on structure of nerves, 525 *note*; on spinal cord, 565 *note*, 566, 567, 568, 569, 570, 602; on medulla oblongata, 575, 578; on origin of spinal accessory nerve, 592; on cilio-spinal centre, 609; on structure of corpora quadrigemina, 605; on the nature of volition, 681 *note*; on structure of cerebrum, 657, 659, 661; on the olfactory nerves, 715 *note*, 716; on development of muscular fibre, 790; on Daltonism, 754 *note*.
Clarke, Dr. Joseph, on weight of new-born infants, 962.
Claremont, lead poisoning at, 106.
Claudet, Mr., his stereomonoscope, 741 *note*.
Clava, 575.
Clavicle, development of, 947.
Cleavage of ovum, 911, 913.
Cleland, Prof., on effect of heat on heart, 288 *note*; on action of intercostals, 352; on cerebral convolutions, 659 *note*.
Clemens, on cutaneous absorption, 190.
Climacteric, diseases of, 1027.
Cloaca, 936, 937, 941.
Cloetta, M., on chemical composition of lung tissue, 347; on inosit, 85.

Cloez, M., on taurocholic acid in adrenals, 444.
Cloquet, on osphresiology, 715 *note*.
Clowes, on pancreatic ferment, 161.
Coates, on inhibition of heart's action, 290 *note*, 295.
Coathupe, Mr., on amount of tidal air, 367.
Coccius, on accommodation, 722.
Coccygeal gland, 217.
Cochlea, structure of, 764; functions of, 774.
Cochlear nerve, distribution of, 764.
Codrington, Sir E., case of, 687.
Cœliac ganglia, effects of extirpation of, 155.
Coffee, effects of use of, 109.
Cohesion of nerve, 526.
Cohn, on cause of splenic fever, 67; on colour sensations, 751.
Cohnheim, M., on migration of white corpuscles, 205, 266, 331; on spleen, 211; on structure of capillaries, 327; on amylolytic ferment, 451; on ending of motor nerves in muscle, 787; on ferment, 69.
Coition, share of male in, 873; of female, 880; duration of influence of, 886 *note*.
Cold, influence of, on tonicity of arteries, 315; influence of, on respiration, 370; power of resisting, variation of, with age, 506; death by, 1031.
Coleridge, S. T., his automatic mental activity, 690.
Colin, on quantity of pancreatic fluid, 160; on digestion of fat, 162; on absorption of salts, 183; on lymph, 200; on heart's impulse, 280; on intercostal muscles, 352; on rapidity of impulses conducted by sympathetic, 553; on sugar in chyle and lymph, 448.
Collagen, 71.
Collard de Martigny, M., on respiration in nitrogen, 379.
Colloids, properties of, 60.
Colm, on Daltonism, 755.
Colostrum, 972, 975.
Colour blindness, 751.
Colourless corpuscles, 231 (see *Blood*).
Colour of skin, variation of, in man, 984.
Colours, vibrations producing, 749; saturation of, 750; intensity of, 750; influence of twilight on, 751; discrimination of, 753; cases of changes of, 985; want of power to discriminate, 751, 754; production of complementary, 751, 754; power of discriminating in blind people, 707.
Columnar cells, 37.
Coma, how different from sleep, 682.
Combe, Dr. A., on digestion, 154 *note*; on influence of passion on mammary secretion, 861 *note*; on influence of mother on fœtus, 906; on infant nutrition, 975 *note*.
Combetti, his case of destruction of cerebellum, 647 *note*; 650 *note*.
Commissures of cerebrum, 602.
Committee Royal Med.-Chirurgical Society on asphyxia, 388.
Comparison of length of limbs as compared with vertebral column, 24 *note*.
Complemental air, 366.
Complementary colours, 751.
Compressed air, effects of respiration of, 375.
Conception, act of, 895; period of, 884.
Conduction of sonorous vibrations, 768.
Conglutin, composition of, 59.
Conia, action of, on heart, 298 *note*.
Connective tissues, 32.
Conner, Dr., on trophic nerves, 857.
Consanguinity, effects of, marriages of, 904 908.
Consciousness, seat of, in sensory ganglia, 680; states of, 680.
Consensual movements, 364, 582, 617, 621.
Conservation of energy, 13, 513, 520.
Consonants, nature of, 840, 842.
Constitution of the sexes, differences in, 965.
Conte, Prof. Le, on correlation of force, 7.
Contour lines of dentine, 54.
Contractile power of muscle, 822.
Contractility of arteries, 305.
——— of blood-vessels, 306.
Conversions of relief, 747.
Convolutions of brain, arrangement of, 30 658; functions of, 670.
Convulsive centre, 611.
Cooper, Sir A., on influence of emotions on mammary secretion, 860; on structure of mammary gland, 967; on blood supply of mammary gland, 969.
Co-ordination of movements, the probable function of the cerebellum, 647–653; influence of habit on, 812; cause of impulses for, 598; centre for, 611.
Copland, Dr., on antiphlogistic regimen, 115, 275.
Cord, spinal, structure of, 566–573; as a conductor of motor impulses and sensory impressions, 596; as an independent centre, 602 (see *Nervous System, Spinal Cord*).
Corfe, Mr., on water at Wolverton, 106 *note*.
Cork, Bishop of, his case of lactation by male, 969 *note*.
Cornaro, on abstinence, 103.
Corn-flour, composition of, 97.
Corona radiata, 619.
Coronary arteries of heart, effects of ligature of, 275.
Corpora amylacea, of Virchow, 451.
——— Malpighiana, of kidney, 457; of spleen, 208.
——— olivaria, 578, 611.
——— pyramidalia, 577.
——— quadrigemina, 589, 605, 617; their functions, 626, 633, 650; development of, 955; effects of stimulating, 627.
——— restiformia, 575, 582, 612, 650.
——— striata, 618, 661; functions of, 127, 604, 618, 619, 629, 630, 633, 644, 648 673; connection of, with cerebrum, 672 effect of lesions of, 630, 631, 679; weight of, 664.
——— Wolffiana, 935.
Corpse lights, explanation of, 519.
Corpus callosum, 668; cases of deficiency of, 677.

Corpus dentatum, 574, 578, 645, 650.
——— luteum, formation of, 881.
——— rhomboideum, 645.
Corpuscles of blood, red, 225; white (see *Blood*).
——— of chyle, 203, 204; their transformation into blood-corpuscles, 204, 252.
Correlation of force, doctrine of, 14 *note*.
Corti, Marquis, on cochlea, 764; organ of, 764, 774; rods of, 765; number of, 766.
Corvisart, on pepsin, 145, 148; on the functions of the pancreas, 163; on bile, 162.
Coste, M., on duration of passage of ova through oviduct, 886 *note*; on decidua reflexa, 888; on development of embryo, 910 *note*.
Coughing, act of, 364, 613, 643, 830; centre for, 641.
Coulomb, M., on amount of work performed by body, 417.
Courvoisier, M., on structure of ganglionic cells, 528, 847.
Cowan, Dr., his case of consensual movements, 635; of apoplexy of cerebellum, 649 *note*.
Cowper's glands, 880 *note*, 941.
Cozé, on glycogeny, 453.
Cranial nerves, origins of, 577–582; distribution of, 588–596.
Cranium, capacity of, 23.
——— of man, compared with that of apes, 19–23; peculiarity of circulation in, 338, typical forms of, 987–989, 997.
Cranio-spinal axis, the fundamental portion of the cerebro-spinal system, 536, 643; development of, 944, 948, 952; comparative anatomy of, 536 (see *Medulla Oblongata*, and *Spinal Cord*).
Crassamentum, 242.
Craufurd, on the colours of different races of man, 985 *note*.
Crawford, Dr., on colour of blood, 261.
Creighton, C., theory on the homology of the adrenals, 882 *note;* on structure of mammary gland, 967 *note;* on development of mammary gland, 968.
Crimean War, effects of inanition during, 115.
Crisp, on spleen, 207.
Critical evacuations, 488.
Croce-Spinelli, on oxygenation of blood in balloon ascents, 14.
Croft, Sir R., on emotions, 861.
Crombie, Dr., on animal heat, 499 *note*.
Crompton, on sense of smell as an aid in diagnosis of disease, 718 *note*.
Cruickshank, on regeneration of nerves, 528 *note*.
Cruorin, 235, 248.
Crura cerebelli, 650.
—— cerebri, fasciculus of Meynert, 631; red nucleus, 631; crusta or basis, 631; tegmentum, 631; locus niger, 631; motor and sensory tracts of, 583, 618; effects of section of, 632, 644; course of fibres in, 619.
Crusta, 631, 662.
—— petrosa, 55.
Cruveilhier, relative capacity of cardiac ventricles, 274; on intercostal muscles, 353.
Crying, act of, 363.
Crystallin, 244.
Crystals of blood, 236.
Cubic space required for respiration, 391.
Cunningham, on germs in air, 428.
Cunze, M., on action of arsenious acid on heart, 298 *note*.
Cup cells, 39; of intestinal villi, 182; of lungs, 344.
Curare, its effects on muscles, 803; on heart, 293, 296.
Curling, Mr., his cases of hypertrophy of the fingers, 458 *note;* on atrophy of bone, 425.
Currie, Dr., on cutaneous absorption, 189.
Cutaneous asphyxia, 507, 508.
——— respiration, 495, 507, 508, 511, 513.
——— sensibility, 700.
——— transpiration, 489–496 (see *Sudoriparous Excretion*).
Cutler, on numeration of red corpuscles, 226, 233.
Cuvier, on the hand, 17; on the intercosta muscles, 352.
Cyanuretted hydrogen gas, effects of respiration of, 385.
Cyon, M. E., on glycogeny, 452.
Cyon, M. M., on action of heat on heart, 288 *note*, 290; on innervation of heart, 295 297, 298 *note;* on depressor nerve, 309 on rapidity of blood current in arteries, 324; on electrotonus, 563; on section of semicircular canals, 628, 629, 773 *note;* on sympathetic nerve, 848; on urea in liver, 480.
Cystin, 80, 461; in urine, 469.
Cytoplasm, 32.
Czajewicz, M., on the development of fat, 44.
Czermak, Dr. J., on deglutition, 118; on influence of vagus on heart, 295; on causes of dyspnœa, 358; on sense of touch, 701; on mechanism of voice, 830.
Czermak's photo-sphygmograph, 316.
Czerny, on rectal digestion, 171; on visual purple, 731 *note*.

DAHM, on the thymus, 214.
Dähnhardt, on secretion of milk, 977.
Dally, Dr. E., on consanguineous marriages, 904 *note*.
Dalton, Dr. J. C., on quantity of food required, 101; on rate of secretion of bile, 167; on effects of ablation of spleen, 211; on biliary acids, 82; on spectrum of bile, 442; on the cerebellum, 647; on corpus luteum, 883 *note;* on spectrum of Pettenkofer's bile test, 443.
Dalton, on rate of conversion of glycogen into sugar, 451; on spectrum notation, 240.
Daltonism, 754.
Dalzell, on tactile papillæ, 699 *note*.
Damaluric acid, 468, 478.
Damolic acid, 468, 478.
Damiens, sleep of, 683 *note*.
Dangel, St. V., on source of urea, 479 *note* on asparaginic acid, 176.

Daniell, Dr., on diaphoresis, 496 *note;* on African fevers, 994 *note;* on death of fever patients, 1029 *note.*
Danilewsky, on ferments, 69; on muscle, 790; on chemistry of contracted muscle, 793; on cerebrum, 668 *note.*
Darwin, Dr. Charles, on the variation of species under domestication, 902, 980, 993 *note:* on geological changes in human period, 1008; on teasel, 33 *note.*
Daturia, action of, on heart, 298 *note.*
Davies, Dr. H., on size of cardiac orifices, 281.
Davis, Dr. N. S., on central lobe of cerebellum, 655; on weight of brain, 664 *note.*
Davy, Dr. J., on temperature of blood in heart, 224; on colour of blood, 261; on venous hue of arterial blood, 223; on absence of coagulation of blood, 250; on effects of loss of blood, 258; on temperature of human body, 498; on milk, 972 *note.*
Deaf and dumb, 839.
Deaf-spots, 775.
Dean, on medulla oblongata, 573 *note.*
Death, the necessary consummation of life, 1028; somatic, 506, 1029; molecular, 506, 1029, 1031; apparent and real, 1032; signs of, 1033; from cold, 509, 1031.
Debouzy, on the iris, 736 *note.*
Decidua, formation of, 887; decidua vera, 888; reflexa, 888; serotina, 888.
Decline, period of, 1026.
Decussation of nerve fibres, 599; of optic nerves, 522.
Deen, Von, on grey substance of spinal cord, 600.
Deer, exuviation of antlers of, 419.
Defecation, act of, 610; centre for, 609, 859; influence of habit on act of, 853.
Degeneration, tendency to, during period of decline, 1026; of type in man, 990, 992, 1006, 1010.
Deglutition, act of, 117, 548, 613; nerves of, 120, 547; centre for, 611.
Deininger, on urea in sweat, 491 *note.*
Deiters, on cerebellum, 645 *note;* cells of, 567, 765.
Delaroche and Berger, MM., their experiments on endurance of heat, 508.
Delau, M., on vocal sounds, 840.
Delbœuf, on the measure of sensation, 778 *note.*
Delore, on cutaneous absorption, 190.
Delphinin, action of, on heart, 298 *note.*
Demant's case of intestinal fistula, 169.
Demarquay, on regeneration of tissues, 427.
Dementia, 680.
Demilune of Giannuzzi, 429.
De Morgan, Mr., on removal of bone by absorption, 419.
Denis, on coagulation, 244.
Dentinal sheaths of Neumann, 54.
Dentine, 54.
Dentition, first, 1016; second, 1020.
Depressor nerve, 309, 310; action on heart, 294, 592, 599, 848.
Desaguliers, Dr., his examples of muscular power, 821.
Descot, M., on regeneration of nerves, 529.
De Sinéty, on cause of parturition, 898 *note;* on Graafian vesicles, 883; on decidua reflexa, 888.
Despretz, M., on musical notes, 760 *note.*
Deutencephalon, development of, 1034.
Deutoplasm, 908.
Deutsch, on lymphatics of gall bladder, 439 *note.*
Development, importance of heat for, 5; spleen and other vascular glands, 211; influence of, on respiration, 370; organ of smell, 900; of embryo, general plan of, 907; earliest stages of, 909; segmentation of yolk, 911; formation of blastodermic vesicle, 908, 912; formation of ectoderm and endoderm, 912; formation of epiblast, 914; mesoblast and hypoblast, 914; formative cells, 914; changes in unfertilized eggs, 914; formation of trilaminate blastoderm, 914; growth of blastoderm, 915; structures derived from epiblast, 915; mesoblast, 915; hypoblast, 915; formation of primitive streak, 915; of primitive groove, 915, 916; vitelline duct, 916; cleavage of mesoblast, 916; formation of pleuro-peritoneal cavity, 916; of somatopleure, 916, 920; of splanchnopleure, 916, 920; of medullary folds or laminæ dorsales, 917, 919; of medullary canal, 917; of noto-chord, 917; of quadrilaminate or secondary blastoderm, 917 *note;* foundation of vertebral column and nervous centres, 917, 920; development of amnion, 917, 918, 925; first appearance of vessels, 918; of allantois, 918; vitelline vessels, 918, 921; heart and arterial system, 918, 923–929; cranial flexure, 919; visceral or branchial clefts, 919; of chorion, 919; of intestine, 920; umbilical vessels, 920, 921, 926; of umbilical vesicle, 921; meatus venosus, 922; hepatic vessels, 922; ductus venosus, 922; bulbus aorticus 923; branchial arches, 924; second form of circulating system, 924, 927; of bladder, 925; urachus, 925; liquor amnii, 926; umbilical cord, 926; ductus arteriosus, 927, 930; aortic arches, 927; ductus Cuvieri, 928; of venæ azygos, 928; sinus venosus, 928; venous system, 928; vestigial fold, 929; fœtal circulation, 929, 930; Eustachian valve, 929; liver, 929, 932; changes in fœtal circulation at birth, 931; on relative thickness of ventricular walls during intra-uterine life, 931; alimentary canal, 931; of pancreas, mucous and peptic glands, 933; lungs, 933; urinary organs, 934–938; of Wolffian bodies, 935; Wolffian duct, 935; kidneys, 936; ureter, 936; of epididymis, 936, 938; of Müllerian duct, 936, 937, 940; sinus urogenitalis, 937; cloaca, 937, 941; of Fallopian tubes, 937 *note;* Gaertner's canals, 937 *note;* vasa deferentia, 937; of adrenals,

938; of urinary bladder, 938; genital ridge, 938, 939, 941; of gubernaculum testis, 938; of vesiculæ seminales, 938; of testes, 938; of ovary, 939; generative apparatus, 938–943; germ epithelium, 939; of primordial ovum, 939; egg clusters, 939; Graafian follicle, 940; of uterus, 940; of vagina, 940; of vesicula prostatica, 940; of external organs of generation, 941; of notochord, 944; skeleton, 944; vertebral column, 944; skull, 948; face, 951; nervous centres, 952; eye and ear, 958; of sex, 961; of the extremities, 961; mammary gland, 968; of muscle, 790; period of, 1013; method of determining age by, 1014.
Devergie, M., on characters of embryo, at different periods, 1014.
Dewar and McKendrick, on electrical disturbance caused by light, 756.
Dewar, on cystin, 80.
Dextrose, 84.
D'Hércourt, Gillibert, on reaction of sweat, 490.
Diabetes, agents producing, 454; centre for, 452.
Diakonow, M., on lecithin, 82.
Diapedesis of white corpuscles of blood, 232; red corpuscles, 331.
Diastase, 68.
Diastema, 21.
Dichroism of blood, 223.
Dicrotous pulse, 314.
Diday, on falsetto voice, 838 *note*.
Diet, animal, 95; vegetable, 96; mixed, 88; of trainers, 104; different scales of, 101; influence of, on composition of blood, 258; on respiration, 371; on composition of urine, 471.
Diet-scales, various, 101.
Diemerbröck, on action of intercostals, 320.
Differential manometer, 319.
Digestion:
Buccal, 137.
Gastric, a process of chemical solution, 148, 155; time required for, 156; action on azotized substances, 148; influence of various conditions on, 157; of milk, 971.
Intestinal, influence of pancreatic fluid in, 161; of bile in, 164; of succus-entericus, 169; its universal efficacy, 169; of milk, 971.
Digestive fluids, relative amounts of, 403.
Digitalis, action of, on heart, 298 *note*; 320.
Dilatation of vessels, 852.
Dilatator nerves, 310.
——— pupillæ, centre for, 611.
Dingo, Australian, breeding of, 1073 *note*.
Dioxindol, 77.
Diphthongs, nature of, 840.
Dipolar molecules, 555.
Directing trabeculæ of bone, 52.
Direction of sounds, judgment of, 773.
Direction, visual sense of, 738; centre of, 738.
Discus proligerus, 881, 884, 940.
Disdiaclasts, 785.
Disodium orthophosphate, 91.
Distance, adaptation of eye to, 722; visual appreciation of, 743; auditory appreciation of, 776.
Distribution of blood, 337.
Ditlevsen, on gustatory nerves, 710 *note*.
Dittmar, on vaso-motor centre, 308, 578.
Diuretics, effects of, on urine, 488.
Diurnal variation, of pulse, 302; of respiration, 373; of temperature, 556.
Dixon, Mr., on nerves of taste, 590 *note*.
Dobell, on pancreatin, 164.
Dobroslawin, on intestinal digestion, 170.
Dobrynin, on allantois, 918 *note*.
Dobson, on the spleen, 210.
Dock, on glycogeny, 449, 450, 452.
Dodd, Mr., his case of early viability, 899 *note*.
Dogiel, M., on sounds of heart, 284; on rapidity of blood current in arteries, 324; on lymphatic absorption, 185; on action of chloroform on heart, 298 *note*.
Dogs, time required to produce asphyxia in, 388.
Döhmen, on dyspnœa, 359.
Dohrn, on muscular sense, 703.
Dolichocephali, 987, 997.
Donders, Prof., on duration of the action of the heart, 277; on inhibition of heart's action, 290 *note*, 292; on capacity of capillary system, 329; on expiratory force, 348, 355; on pressure of inspiration and expiration, 355; on quantity of urine, 465; on perspiration, 494; on limits of pitch of vocal sounds, 938; on rapidity of transmission of motor impulses through nerves, 553, 797; on absolute muscle force, 822; on astigmatism, 727; on the limits of clear vision in health, 724; on the symmetrical movements of the eye, 819; on presbyopia, 727; on sound colours, 770 *note;* on work in muscle, 822; on food in relation to work, 825 *note*.
Dönitz, on muscle, 784 *note*.
Donné, M., on temperature in disease, 505; on development of electricity in living body, 521; on human milk, 972, 975 *note*.
Donovan, Dr., on Irish starvation, 113; on evolution of light, 520.
Dormant vitality, 2 *note*.
D'Ornellas, on vomiting, 125.
Dove, on colours, 751 *note*.
Dowler, Dr. Bennet, on post-mortem elevation of temperature, 506; on post-mortem movements, 809.
Dragendorf, on gastric juice, 146.
Drasch, on forms of glomeruli in kidney, 459 *note*.
Dreaming, 682, 690; effect of drugs on, 691.
Dreschfeld, on vaso-motor centre, 308.
Drink, water the natural, 105; influence of, on composition of blood, 257; effects of alcoholic, 106.

Drosdoff, on division of splenic nerves, 210; comparison of portal with hepatic venous blood, 262; on migration of white corpuscles, 303.
Drosdow, on cardiac ganglia, 287 *note*.
Du Bois-Reymond (see *Bois-Reymond, du*).
Dubreuil and Legros, MM., on influence of sulphocyanide of potassium on heart, 297 *note*.
Dubrisay, on globular richness of blood, 225, 226, 233.
Duchenne, on intercostals, 352 *note;* on respiratory nerve centres, 357; on locomotion, 813; on trophic nerves, 854.
Ducks, time required to produce asphyxia in, 388.
Ductless glands, structure and functions of, 206, 218.
Ductus arteriosus, S. Botalli, 928, 930.
——— Cuvieri, 928.
——— venosus, 922.
Duffin, Dr., on the stimuli affecting nerve and muscle respectively, 802 *note*.
Dufresne, on pancreatic ferment, 70.
Dugès, M., on function of cerebellum, 650; on the ova of batrachia, 909 *note*.
Dulong, M., on calorification, 513.
Dumas, on ferments, 66; on formation of fat, 413.
Duncan, Dr. M., on rapidity of blood current, 329 *note;* on fertility of females, 879 *note;* on time of parturition, 896; on epithelial lining of uterus during pregnancy, 897; on rate of movement of fluids through tubes, 324.
Dunglison, Prof., on sounds of heart, 284 *note;* on temperature in disease, 505; heat of uterus in parturition, 510 *note;* on temperature of paralyzed limbs, 504; his cases of peculiar secretion of milk, 969 *note*.
Dunkin, on time of parturition, 895 *note*.
Dunn, Mr., on automatic actions, 117; his cases of apoplexy of cerebellum, 649 *note*, 650, 655.
Dupré, M. A., on animal quinoidin, 81; on alcohol, 107; on rapidity of absorption from stomach, 183.
Dupuy, M., on injection of cerebral substance into veins, 248; on electrical excitation of cerebrum, 673 *note*.
Duration, relative, of different parts of the organism, 399; of after-sensations, 714, 718, 748.
Durham, Mr. A., on the condition of the circulation in the brain during sleep, 339, 681.
Duroy, on alcohol, 107.
Dursy, on primitive streak and groove, 915 *note*.
Duval, on intercostal muscles, 352; on regeneration of tissues, 427; on origin of 4th nerve, 581; on cranial nerves, 594; on appreciation of sounds, 766; on development of spermatozoa, 871.
Duverney's glands, 880 *note*.
Dwight, on muscle, 784 *note*.
Dybkowsky, M., on lymphatic absorption, 185; on movement of lymph, 206; on hæmoglobin, 237; on action of antiaris on heart, 297 *note;* on rise of temperature in rigor mortis, 506 *note*, 793.
Dyspepton, 149.
Dysperistalsis, 126.
Dyspnœa, causes of, 359; from heat, 507.
Dyslysin, 81, 441 *note*.
Dzondi, on deglutition, 119.

EAR, 765; external, 775; meatus, 775; middle, 769; internal, 763, 772; development of, 958; ossicula auditûs, 770 (see *Hearing, organ of*).
Earle, Dr. Pliny, on want of power to discriminate musical notes, 775 *note*.
Earle, Mr. H., on temperature of paralysed limbs, 504.
Earthy phosphates in urine, 482.
Easkell, on blood-flow in muscle, 807.
Eberhard, on absorption of solid particles, 185.
Eberth, M., on adrenals, 212; on muscular fibres of heart, 274; on lymphatics of heart, 275; on structure of small arteries, 305 *note;* on structure of capillaries, 327; on structure of veins, 333; on biliary ducts, 437; on muscular tissue of heart, 783; on ciliated epithelium, 781; on contractility of capillaries, 328.
Ebner, v., on development of spermatozoa, 871 *note*.
Ebstein, on pepsin, 147.
Ecker, Prof., on thymus, 215; on convolutions of cerebrum, 658 *note*, 672; on nerves of touch, 699 *note*.
Eckhard, Prof., on influence of nervous system on erection, 340, 852 *note;* on glycosuria, 452; on electrotonus, 559; on the nodus cursorius, 631 *note;* on development of muscle, 791; on influence of changes of temperature on nerves, 550, 551; on electrical condition of nerves, 561.
Economy, balance of vital, 402 (see *Vital Economy*).
Ectoderm, 914; formation of, 912.
Ectosteal ossification, 52, 53.
Ectostosis, 947.
Edis, on nerve lesions, 855 *note*.
Edwards, Dr. W., on irritability of heart in young animals, 276; on respiration in hydrogen, 379; on absorption and elimination of nitrogen, 381; on temperature in tetanus, 505; on temperature of infants, 499 *note;* on seasonal variation of calorific power, 503; on inferior calorifying power of young animals, 509, 517.
Effective energy of various compounds when consumed in the body, 416.
Effects of respiration on air, 369 *et seq*.
Effects of temperature—on respiratory process, 370; on moisture of air, 370; on age, 370; on sex, 370; on development of body, 370; on food, 371; on muscular exertion, 372; on repose, 372; on sleep, 372; on period

of day, 373; on season, 373; on frequency of respiratory acts, 374; on state of health or disease, 374.
Efferent nerve-fibres, 527, 543, 546, 564, 604, 624; variations in excitability of, 551; electrical conditions of, 554; influence of electrical currents on, 561.
Egesta, chemical composition of, for one day, 404; relative proportion of, discharged by different excretory organs, 404, 405.
Egg albumin, composition of, 59; characters of, 61, 244.
Egg clusters, 939.
Eggs, composition of, 97.
Ehrenberg, Prof., on limits of vision, 733, 734.
Eichhorst, on absorption from rectum, 187; on effects of section of vagus, 365.
Eichwald, on fibrin, 244.
Eidoptometry, 733.
Eimer, M. T., on corpuscula tactûs, 699 *note;* on movements of nucleoli, 35.
Einbrodt, M., on influence of respiration on blood pressure, 323.
Eisenmenger, on action of various drugs on muscle, 802 *note.*
Ejaculatio seminis, 873; its independence of sensation, 609.
Elasticity of arteries, 305; of veins, 333; of lungs, 348; of walls of chest, 354; of muscular tissue, 794; of nerves, 526.
Elastic tissue, 39, 42.
Elastin, 71.
Electricity, evolution of, in living body, 497, 520; connection of, with nutritive and secretory operations, 521; muscular current of, 521, 796; disturbance of, in muscular contraction, 871; nervous current of, 553; disturbance of, in nervous action, 557; disequilibrium of, 522; in optic nerve, 756; on electrical condition of the blood and tissues, 521; on heart, 287; on brain, 672; on nerves of special sense, 772; on nerves, 849; on muscular contraction, 825.
Electrotonus, 544, 556; of Hermann, 556; of Pflüger, 557, 563; explanation of, 563.
Elliotson, Dr., on number of respiratory movements, 356.
Elliptical skull, 989.
Elson, Dr., on action of cinchonin on heart, 298 *note.*
Embryo, development of, 907 (see *Development*); determination of age of, 1014.
Embryonal cartilage, 45.
Embryonic life, peculiarities of,
Emerson, Dr., on infantile mortality, 518 *note.*
Emetin, action of, on heart, 298 *note;* effects of, 125.
Emigration of white corpuscles, 331.
Emmetropia, 724.
Emminghaus, on transudates, 205, 475; on flow of lymph, 333.
Emotional movements, 364.
Emotions, influence of, on digestion, 839; on pulse, 302, 538, 640; excitation of, by muscular suggestion, 680, 693; their action on organic functions, 850, 853; influence of, on stammering, 844; relation to cerebro-spinal system, 540; nervous centres for, 618; effect of, on secretion of milk, 860.
Emulsin, 68.
Enamel of teeth, 54.
——— organ, 56.
Encephalic circulation, 339.
Endemans, on air of New York, 393.
Enderlin, on fæces, 173.
Endocardium, nerves of, 276.
Endoderm, formation of, 912.
Endogenous cell formation, 35.
Endolymph, 773.
Endoneurium, 523.
Endosteal ossification, 51, 53.
Endosteum, 48.
Endostosis, 947.
Endothelium, 36, 196; of arteries, 305; of nerves, 523.
Energy, conservation of, 513, 520 *note.*
Engel, M., on development of cerebellum, 645.
Engelmann, influence of heat upon the vegetable organism, 497; on heart, 288 *note;* on protoplasm, 33; on intestinal movements, 123; on gustatory bulbs, 710; on ciliary movements, 781; on muscle, 784 *note,* 785, 799 *note;* on termination of motor nerves, 787; on nerve currents, 555.
Enteric fluid, digestive power of, 168.
Entoptical phenomena, 758.
Enzyme, 64.
Epencephalon, development of, 919.
Epiblast, 914; structures derived from, 915.
Epidemic diseases from insufficient respiration, 394.
Epidermis, 37.
Epididymis, structure of, 878; development of, 936.
Epineurium, 523.
Epiotic, 951.
Epithelium, 36; tessellated, 36; ribbed, 37; columnar or cylindrical, 37; cup, 38; goblet, 38; spheroidal, 38; ciliated, 781; germinal, 936; peritoneal, 936; germ, 939.
Epoophoron, 942.
Erb, on fatty degeneration of muscle, 420, 857; on animal heat, 504 *note.*
Erdmann, on cells of villi, 132.
Erectile tissues, circulation in, 339.
Erection, 654, 853; centre for, 609, 873.
Erect vision, cause of, 738.
Ergot, action of, on heart, 298 *note;* as cause of gangrene, 1024.
Erichsen, Prof., on rate of absorption, 183; on effects of ligature on coronary artery, 275; on asphyxia, 391 *note.*
Erismann, on perspiration, 492 *note,* 494.
Erman, on protracted lactation, 975 *note.*
Erotic sense, 651.
Eruption of teeth, 57.
Erythrodextrin, 83.
Erythrogranulose, 83.

Erythrozyme, 68.
Esquimaux race, 1007; their food, 95; pyramidal skull of, 1007.
Estor and St. Pierre, MM., on gases of blood, 343 *note*.
Ethidene lactic acid, 86.
Ethiopian race, 1003.
Etzinger, on digestibility of cartilage, 95.
Eulenberg and Guttmann, MM., on action of bromide of potassium on heart, 319 *note;* on excitation of the sympathetic, 515, 851.
Eulenberg, M., on absorption of salts, 183; on action of nicotin and quinine on heart, 298 *note;* on cerebrum, 673, 676; on muscular sense, 703.
Eupnœa, 358.
European nations, 998.
Euskarian language, 999.
Eustachian tube, functions of, 771.
——— valve, uses of, 927, 929.
Evanson, Dr., his case of abolition of sexual desire, 655 *note*.
Ewald, on rate of movement of blood in capillaries, 329; on salivary glands, 131, 139; on respiration, 351; on respiratory force, 355; on dyspnœa, 384; on glycogen, 454.
Ewart, Cossar, on Bacillus anthracis, 67.
Excito-motor actions of spinal axis, 530, 632 *note*, 614; their independence of sensation, 531, 634; their adaptive character, 532; their relation to the organic function, 532; their subservience to locomotion, 532; their establishment by habit, 636.
Excretion, general nature of, 428; sources of demand for, 430; statics of, 404; complementary relation of different modes of, 430; vicarious forms of, 431.
Excretin, 173.
Excretolic acid, 173.
Exercise, influence of, on excretion of carbonic acid, 401; on pulse, 302; on composition of urine, 472, 475, 482; on temperature of body, 500; on growth of muscle, 791; on muscle, 824.
Exhalation of aqueous vapour, from lungs, 382; from skin, 411, 494; from dead body, 494; frigorific effect of, 508.
Exhaustion, muscular laws of, 793; causes of death by, 511, 810.
Exner, on time of reflex acts, 673; on olfactory cells, 715 *note*.
Expectant attention, 853.
Expiration, effects of, on blood pressure, 322; movements of, 350; muscles of, 352; force required for, 355.
Expiratory muscles, 352; power of, 355.
Extensibility of nerve, 576.
Extension, sense of, 702.
Externality, elementary notion of, 737.
Extractives of blood, 254; of urine, 478.
Extremities, development of, 961.
Exuviation of effete tissues, 453.
Eydoux and Soulyet, on animal heat, 498.
Eye, optical structure of, 721; adaptation of, to distances, 722; nervous organization of (see *Retina*); use of, in vision (see *Vision*); development of, 720, 958; tension of, 720 *note;* intra-ocular pressure, 719 *note;* emmetropic, 724; refractive surfaces of, 720; index of refraction, 720; principal points of, 721; nodal points of, 721; positive accommodation of, 722; negative accommodation of, 723; blind spot, 725; excursion of, 725; convergence of, 725; amount of light admitted to, 734; influence of sympathetic on, 851; influence of nervous system on nutrition of, 858.
Eyeball, movements of, 628, 817–20.
Eyes, convergence of axes of, in object, 725, 740, 746; movements of, directed by visual sense, 820; relation of will to, 819; harmony and symmetry of, 817–820; centres for, 610, 611.

FABRICIUS, on closure of pupil, 736.
Facial angle of man and apes, 22,23.
Facial nerve, deep origin of, 580; distribution and functions of, 589, 624, 770.
Face, development of, 951.
Fæces, composition of, 172, 405; expulsion of, 130; average daily quantity of, 172, 406.
Fagge and Stevenson, Drs., on action of poisons on heart, 297.
Fährer, effects of ablation of spleen, 223.
Fakeers, Indian, apparent death of, 1032.
Falck, on origin of urea, 536.
Falk, on effects of respiration of dry air, 393.
Fallopian tubes, development of, 937 *note;* passage of spermatozoa through, 880, 884; passage of ova through, 884; formation of chorion in, 886.
Falsetto voice, nature of, 836; double, 838.
Faraday, Prof., on visual illusions, 748.
Faria, Abbé, on somnambulism, 686.
Farinaceous constituents of food, 93, 96, 161; importance of, in production of muscular force, 472.
Faroese islanders, diet of, 105.
Farr, Dr. W., on zymotic affections, 286.
Farre, Dr. Arthur, on decidua reflexa, 888; on uterine sinuses, 848.
Fasci, L. M., on muscular contraction, 792 *note*.
Fasciculi teretes, 581.
Fasting, balance of economy in, 406.
Fat, structure, uses, and development of, 45–47; variations of, 414; amount of, in blood, 268, 421; in old age, 1026; in milk, 897 *note;* in chyme, emulsification of, 162; in fæces, 172; effects of, when taken with meat, 408; origin of, 413, 414; proportion of, in blood, 415; in adipose tissue, 415; in brain, 415, 529; in nerves, 415, 529; in milk, 973; disappearance during starvation, 511.
Favre, M., on sweat, 490, 492; on calorific equivalents, 570.

Favre and Silbermann, MM., on heat of combustion, 513.
Fayrer and Ludwig, on effects of extirpation of spleen, 219.
Fayrer, Sir Joseph, on elimination of snake poison, 284; on snake bites, 289, 292.
Febrile states, effects on blood, 380.
Fechner, Dr. G. Th., on appreciation of weight, 703; his psycho-physical law, 778 780.
Fecundation, seat of, 884; act of, 873; uses of, 902.
Feder, on source of urea, 474 *note.*
Feinberg, on suppression of cutaneous respiration, 495.
Fellenberg, Dr. C., on recedence of near-point with advancing age, 724.
Feltz, on migration of white corpuscles, 478; on pigments of bile and blood, 442 *note;* on jaundice, 447.
Female, physiological peculiarities of (see *Sexes*); mental constitution of, 965; length and weight of, at birth, 962–964; subsequent increase of, 1043; viability of, 963; puberty of, 877; influence of, on progeny, 962; on sex, 962; share of, in generation (see *Generation*).
Fenestra ovalis and rotunda, 772.
Fermentation, 65; lactic acid, 86; alcoholic, 65; mechanical theory of, 65; vitalist theory of, 65; lactic acid, 66; butyric acid, 66; acetic, 66; bacteria, 67.
Ferments, 64; soluble, 67; inversive, 69; unorganised, 68, 69; amylolytic, 69; proteolytic, 69; causing coagulation of blood, 242, 245; experiments in support of the existence of fibrin ferment, 245; method of isolating, 245; in bile, 441; in liver, 451; in urine, 467, 469; in milk, 971, 977; casein, 977; in lymph, 202; in muscle, 789; lactic acid ferment, 789; myosin, 810; casein, 977.
Fernet, M., on gases of blood, 255, 256.
Ferrein, on vocal ligaments, 832.
Ferrier, Dr., on electrical excitation of cerebral convolutions, 670; on corpora quadrigemina, 617, 627, *et seqq.* 630.
Fibrillæ, 784.
Fibrin, composition of, 59; factors, 242.
Fibrin, 63; of blood, artificial formation of, 244; origin of, 244, 246; normal proportion of, 254; increased proportion of, in arterial blood, 261; in splenic vein, 246; augmentation of, in inflammation, 244, 247, 265; diminution of, in adynamic diseases, 244, 247; its coagulation, 242 (see *Coagulation*); ferment, 242.
——— of chyle, 202.
——— of lymph, 202.
Fibrinogen, 242, 244.
Fibrino-plastin, 63, 242, 244.
Fibrinous effusions of inflammation, 277, 475; conservative nature of, 466.
Fibro-cartilage, 45.
Fibrous tissue, 39.
Fick and Wislicenus, MM., on elimination of nitrogen by the urine, 13, 93, 472.
Fick, Prof. A., on secretion of gastric juice, 148; on action of spartein on heart, 298 *note;* his spring kymograph, 321, 343; on force required for respiration, 355; on heat dyspnœa, 507; on cochlea, 764; on nerves of touch, 699 *note;* on sense of touch, 701; on sensations of temperature, 705; on colour zones of retina, 751; on rise of temperature in rigor mortis, 506 *note,* 794; on contraction of muscle, 501, 798; on elasticity of muscle, 795; on absolute muscle force, 822; on Proteid metabolism, 462.
Fifth pair of nerves, origin of, 580, 581; distribution and functions of, 584; its action on sight, 856; cardiac nerves, 592; influence on salivary secretion, 592; on lachrymal, 585: on eye, 585; trophic root, 584; trophic fibres of, 855, 370, 619, 585, 586; in respiration, 362, 592; its agency in taste, 590, 624, 708; in smell, 620, 716; union of lingual with hypoglossal, 544.
Figuier, on glycogeny, 448.
Filum terminale, structure of, 565 *note.*
Finkler, on influence of climate on temperature, 499 *note.*
Finlayson, Dr., on temperature of infants, 499.
Finn, on glycogeny, 449.
Finnish race, 999, 1002.
Fischer, on trophic nerves, 858; influence of nervous system on animal heat, 503 *note.*
Fission of cells, 36.
Flacetodezza, cause of, 67.
Flagellata, 33.
Flechsig, on spinal cord, 570, 619.
Fleischer, on formation of fat, 414.
Fleischl, on lymphatics of liver capsule, 439 *note.*
Flês, Dr., his case of atrophy of liver and pancreas, 164.
Flesh, amount of nitrogen in, 406.
Flint, Dr. Austin, on cholesterin, 89; on stercorin, 90; on bile capillaries, 437 *note;* on secretion of bile, 167; on semilunar valves of heart, 280; on bile ducts, 437 *note;* on jaundice, 445; on effects of exercise on urea, 474, 824 *note;* on uric acid, 425; on muscle force, 824.
Flögel, on muscle, 784 *note,* 785.
Flourens, M., on enlargement of arteries with pulse, 312; on nœud vital, 356; on reflex action, 606; on removal of cerebrum, 627, 877 *note;* on functions of corpora quadrigemina, 625; on auditory nerve, 624, 628; on vertigo, 628; on thalami optici, 630; on typical skulls, 987 *note;* on section of semicircular canals, 773.
Flower, Prof., on comparative anatomy liver, 433.
Flügge, time of circulation in liver, 435.
Fluoride of calcium in fossil bones, 50 *note.*
Flute-pipes, laws of, 833.

Fodéré, on inanition, 116.
Fœtal cartilage, 45.
Fœtus, mode of determining age of, 1014; size and weight of, at birth, 962; development of organs in (see *Development*); condition of, in utero, 688.
Folet, M., on temperature of paralysed parts, 504.
Follicles of Lieberkühn, 168, 169.
Folwarzy, on lithium in blood, 256.
Fontana, on regeneration of nerves, 528 *note*.
Food, the primary source of neuro-muscular energy, 15; classification of components of, 92; saccharine constituents of, 93; oleaginous constituents of, 93; albuminous constituents of, 94; gelatinous constituents of, 94; proportions of carbon and nitrogen in different articles of, 96; calorific and histogenetic value of, 97; most economical combinations of, 96; composition of various kinds of, 97; relative value of animal and vegetable, 98; quantity of, needed by man, 101, 402; importance of purity of, 105; consequence of deficiency of, 109; prehension and ingestion of, 116; relative digestibility of different kinds of, 156; influence of nature of, on composition of blood, 257; on respiration, 371; on excretion, 514; on the temperature, 510; instinctive choice of, 713; milk as, 976; animal, composition of, 97; vegetable, composition of, 97.
Foot of man compared with that of apes, 18.
Foramen ovale, 930.
Ford, Hudson, on alcohol in blood, 255.
Ford, Mr., his case of absorption in ovarian dropsy, 190.
Fordyce and Blagden, Drs., their experiments on endurance of heat, 508.
Forebrain, 954.
Foraminifera, 33.
Form, mode of acquiring knowledge of, by touch, 702; by vision, 737.
Formad, on nervous supply of iris, 735.
Formative Power, formative cells, 814; its greater energy in earlier than in later periods of life, 1012.
Förscher, on nerve regeneration, 528 *note*.
Förster, on field of vision, 724, 756.
Fort, on functions of mesocephalon, 633.
Fort Sumter, state of prisoners in, 114.
Fortunatow, on nerves of villi, 179.
Foster and Balfour, on development of fowl, 252, 886, 909 *notes;* of liver, 932.
Foster, Dr. M., on amylolytic power of pancreatic fluid, 161; on cardio-motor ganglia, 290 *note;* on heart of snail, 292; on action of intercostals, 352; on glycogen, 450; on coagulation of blood, 244 *note;* on ferments, 69, 70, 161.
Fothergill, on digitalis, 298 *note;* on temperature in disease, 505.
Foulis, on voice, 842; on ovary, 874 *note*, 876 *note;* on development of ovary, 939, 940 *note;* on development of vertebral column, 945.
Fourcault, Dr., on cutaneous asphyxia, 495.
Fourdanet, on respiration of compressed air, 375.
Fournié, on excitation of cerebral convolutions, 674, 676 *note*.
Fourth pair of nerves, origin of, 581; distribution of, 588.
Fovea centralis, 732, 751.
Foville, M., on function of cerebellum, 650; on condition of brain in insanity, 678.
Fowler, on inanition, 113.
Fox, Dr. Wilson, on development of muscle, 791 *note*.
Franck, on latent period of brain, 673; on contraction of pupil, 735 *note*.
Frankland, Dr., on disintegration of muscle, 93; on amount of heat produced, 513.
Franklin, Sir J., on temperature, 506; his case of lactation by male, 969 *note*.
Frantzel, M., on nerve cells, 528 *note*, 847.
Franque, on urea, 471.
Fraser, Dr. T. R., on physiological action of Calabar bean, 297 *note;* on action of various compounds on nerve and muscle, 803, 287 *note*.
Free cell formation, 34.
Frerichs, Prof., on leucin, 75; on composition of semen, 869; on gastric juice, 146; on composition of bile, 440; on meconium, 445; on glycogeny, 447, 483; on excretion of urea, 475, 480; on uræmia, 463.
Frey, Prof., on structure of lymphatic glands, 195; on thyroid, 216; on dilator nerves, 310; on biliary ducts, 437, 439.
Freyer, on cells of spleen, 209.
Friedländer, on pressure under which bile is secreted, 167; on action of heart, 285 *note;* on effects of deficiency of oxygen, 359; on section of vagus, 365; on respiration of oxygen, 385.
Friedleben, M., on composition of thymus gland, 215.
Fritsch, on electrical excitation of brain, 670, 673.
Frogs, respiration in, 377; effects of injecting saline solutions into, 380.
Frohde's test for albumin, 60.
Fröhlich, on influence of position on pulse, 301.
Frommann, Dr. C., on structure of spina cord, 570 *note;* of nerves, 524.
Fubini, on cutaneous respiration, 377.
Functions, vital (see *Absorption, Assimilation, Circulation*, &c.)
Fundamental notes, 760.
Fungi, action of light upon, 7.
Fungiform papillæ of tongue, 709.
Funke, Dr. Otto, on absorption of fat, 181; on absorption of peptone, 186; on blood crystals, 239; on blood pressure, 322; on Traube's curves, 323; on perspiration, 491, 492; on regulating mechanism for heat, 508; on temperature of brain, 498, 516; on reaction of nerve, 549; on effects of curare on motor and sensory

nerves, 298 *note*, 803 ; on law of contraction, 561.
Fuscin needles, 731.
Fusion of cells, 36.

GABOR, on poisons of heart, 298 *note*.
Gad, on emulsification of fats, 162.
Gadden, on optic commissure, 627.
Gaertner's canals, 937 *note*.
Gaetghens, on glycogeny, 456; on source of urea, 479 *note*, 483.
Gairdner, Dr. W. T., on blood, 261 ; on contractility of bronchial tubes, 348 ; on kidney, 456 *note*.
Galabin, on the sphygmograph, 315.
Galactophorous ducts, 967.
Galen, on action of intercostals, 352.
Galezowski, on iris, 736 *note*.
Gall, on amative function of cerebellum, 651 ; on comparative development of cerebrum, 668, 669.
Gall bladder, position of, 433.
Galton, on composite portraits, 743 ; on visualisation, 758 ; on heredity, 904 *note*.
Galvanoscopic frog, 554.
Galvano-tetanus, 549.
Galvano-tonus, 549.
Gamgee, Prof., on cystin, 80 ; on bile, 166, 446; on specific heat of blood, 224; on influence of nitrites on blood, 241; on rapidity of blood current, 324; on coagulation of blood, 242 ; on vagus, 293 *note*.
Ganglia of sympathetic system, 506, 846.
Ganglia, structure of, 286, 523, 527, 528, 548, 585, 617 *et seq.*, 847 (see *Nervous System*).
Ganglion stellatum, 296.
Gangrene, death by, 1032.
Garcia, on falsetto voice, 837.
Garrod, A. H., on active dilatation of heart, 276 *note;* on cardiographic tracings, 282 *note;* on effect of heat on heart, 288 *note*.
Garrod, Dr., on salines of blood in cholera, 268 ; on uric acid in blood, 476 ; on sweating, 493.
Gaskell, on dilating nerves, 852.
Gasserian ganglion, 535, 846 ; its influence on nutrition, 937; on the eye, 735.
Gasser, on development of urinary organs, 934 *note;* 935.
Gases found in the alimentary canal, 175 ; in the blood, 258 ; effects of breathing various, 359.
Gastric ferment, 69.
——— follicles, structure of, 143.
——— juice, composition of, 145 ; conditions of its secretion, 151 ; quantity of, secreted daily, 146, 403 ; influence of nervous system on, 154 ; solvent power of, 155.
——— venous blood, 263.
Gaule, negative diastolic pressure in auricles, 276 ; on cardiac pressure, 276 *note*.
Gegenbauer, on osteoblasts, 51 ; on development of vertebral column, 946.
Gehler, on double vision, 740.
Gelatin, 71 ; uses of, as food, 94 ; peptic digestion of, 150.
Gelatinous nerve fibres, 847.
Gellé, on resonance of voice, 771.
Gemmation, multiplication of cells by, 36, 865.
Gendrin, on maturation of ova, 879.
Generation, general nature of, 864 ; provisions for its performance, 865, 867; spontaneous, 865 ; by fission, 866 ; relation of cerebellum to, 651, *et seq.* ; organs of, their development, 938–943.
Action of *Male* in, 867 ; structure of testes, 867 ; characters of seminal fluid, 869 ; nature and evolution of spermatozoa, 870 ; essential importance of spermatozoa in fecundation, 871 ; puberty, epoch of, 872 ; of sexual desire, 873 ; coition, 873.
Action of *Female* in, 874 ; structure of ovum, 875 ; evolution of ovum, 876 ; period of puberty, 877 ; menstrual discharge, 878 ; coincident ovulation, 878 ; duration of procreating period, 879 ; her function in coition, 880 ; maturation of ova, 881 ; corpus luteum, 881 ; changes in ovum previous to fertilization, 885 ; fecundation of ovum, 884, 885 ; consequent changes, 885 ; formation of chorion, 886 ; formation of decidua, 887 ; of villi of chorion, 890 ; of fœtal tufts, 891 ; of placenta, 891 ; changes in uterus during gestation, 887, 893 ; quickening, 895 ; parturition, act of, 895 ; period of, 897 ; superfœtation, 901 ; see *Lactation, Mammary Gland, Milk*.
Influence of *Parents* on progeny, 902; effects of near relationship of, 903 ; influence of male on subsequent offspring, 893, 905 ; effects of state of parents at time of conception, 906 ; subsequent influence of mother, 906, 931 ; influence of ages of parents on sex of progeny, 961.
Embryonic Development (see *Development of Embryo*).
Generative force, its dependence on heat, 10.
Genersich, on lymphatic system, 193 *note;* on lymph, 200 ; on effects of movement on flow of lymph, 333 *note*.
Genital ridge, 938.
Genito-spinal centre, 609.
Genius, 670.
Genth, on excretion of uric acid, 475; of urea, 471 ; of salts, 483.
Gerlach, on nerves of intestines, 126; on structure of kidney, 456 *note*, 514 ; on spinal cord, 565 *note*, 567, 570 *note;* on cerebrum, 659 *note;* on nerves of touch, 699 *note*.
Germ cell, 866.
—— theory, 865.
Germinal membrane, 913.
——— matter, 32.
——— spot, 875, 911.
——— vesicle, 866, 875, 911 ; segmentation of, 885.

Gestation, ordinary term of, 895, 897; abbreviated, 899; protracted, 897, 899; signs of, 895.
Ghert, Von, on effects of exertion on respiration and circulation, 356.
Giaffré, on nerve stimuli, 548 *note*.
Giannuzzi, on sympathetic nerve, 847; on conditions affecting the secretion of saliva, 129; on lymphatics of glandular organs, 193; on mammary gland, 967 *note*.
Giant cells, 218, 419.
Gibb, Dr. G., on the laryngoscope, referred-to, 832 *note*.
Gibbes, Heneage, on structure of spermatozoa, 870 *note*.
Gilbert and Lawes, Messrs., on the mode of fattening animals, 413.
Gilchrist, Dr., on effects of section of vagi, 360.
Gillett, on deglutition, 119; on trophic nerves, 855 *note*.
Girdwood, Mr., on periodical discharge of ova, 879, 884.
Glaisher, Mr., his balloon ascents, 376.
Glands, assimilating, of absorbent system, 195; development of, 932, 933; vascular, 206; their functions, 218; salivary, 132; gastric, 143; pancreatic, 158; lymphatic, 194; liver, 433; kidney, 456; Brünner's, 168; sweat, 489; mammary, 966; secreting, essential nature of, 428.
Glandula coccygea, 217.
——— intercarotica, 217.
Glikz, on lesions of corpus striatum, 630.
Glisson, capsule of, 434.
Globular richness of blood, 225.
Globulin, 244; composition of, 59; characters of, 63.
Glomerulus, 458.
Glosso-pharyngeal nerve, origin of, 579; distribution and functions of, 545, 546, 590, 595; its instrumentality in deglutition, 547, 590; in sense of taste, 590, 624, 708 *note*; number of fibres in, 591; mode of termination of gustatory fibres of, 710.
Glottis, regulation of, 826, 830; changes in, during production of sounds, 831; artificial, 834.
Gluge and Thiernesse, on union of sensory with motor nerves, 544.
Glutin, 71.
Glycin, 82, 412; in urine, 469.
Glycocholic acid, 82, 413, 441, 445.
Glycocin, 82.
Glycocol, 79, 82, 441, 444, 477.
Glycogen, 76, 438, 447; action of pancreatic juice on, 161; conditions affecting formation of, 449, 450; presence of, in various tissues and animals, 450; effect of ferment upon, 451; effect of drugs on, 453–454; effect of respiratory disturbance upon, 454; effect of vascular disturbance upon, 454; uses of, 455; formation of, from oleaginous materials, 455; abundance of, in embryonic tissues, 456; composition of, 85; theories of origin of, 447; amount in different animals, 449; in muscle, 790.
Glycogeny and glycogenic function of the liver, 439, 447; influence of nervous system upon, 452; effects of various agents on, 449, 454; effects of food on, 448–449.
Glycose, 83.
Gmelin, on bile, 441.
Goblet cells of lungs, 344.
Gobley, on urea in blood, 264.
Goldstein, on respiration with deficiency of oxygen, 387; on effect of temperature on respiration, 358; on heat dyspnœa, 507.
Golgi, on fatty degeneration of muscle, 420.
Goll, column of, 566, 568, 575, 596, 602; on rapidity of flow of urine, 465, 466.
Goltz, on negative diastolic pressure in auricles, 276; on movements of œsophagus, 121; on intestine, 128; on cardiac pressure, 276 *note*; on inhibitory nerves of heart, 290 *note*; on action of poisons on heart, 298 *note*; on erection, 340; on migration of white corpuscles, 333; on nervous centre of bladder, 488, 489; on section of semicircular canals, 628, 774; on vaso-motor nerves, 852 *note*; on functions of cerebrum, 626 *note*.
Goodsir, Prof., on structure of kidney, referred-to, 456 *note*; on structure of decidua, 890 *note*.
Gordon, on ventricles of heart, 274.
Gorilla, comparison of, with man, 17–35.
Gorup-Besanez, v., on test for peptones, 149; on spleen, 210; on thymus gland, 215; on fibrin in blood, 261; on formation of fat, 413; on composition of the bile, 440; on urine, 469, 472, 484; on composition of nervous tissue, 530; on composition of semen, 868 *note*; on reaction of milk, 970 *note*.
Götte, on development, 910 *note*; on theory of formation of blastoderm, 913 *note*; on formative cells, 914 *note*.
Götting, on nervous mechanism of secretion of sweat, 491 *note*.
Gottstein, on cochlea, 764 *note*.
Gough, John, case of, 707.
Gower's hæmatocytometer, 226.
Graafian follicle, 875; development of, 940; formation of ovum within, 876; escape of ovum from, 881; subsequent changes in, 881–883.
Gräfe, Prof. Von, on glycogeny, 508; on paralysis of fifth nerve, 586; his case of removal of iris, 724; on Calabar bean, 727; on movements of the eye, 817 *note*.
Gräfe and Sämisch, on accommodation, 722 *note*.
Graham, Prof., on osmosis, 185.
Grailich, on colours, 751 *note*.
Grainger, on reflex action, 603.
Grandeau, M., on effects of injecting salts into blood, 92, 287.
Grandry, M., on adrenals, 212.
Granulose, 83.

Granville, Dr., on heat of uterus in parturition, 509 *note*.
Grape sugar, 84 ; in urine, 469.
Gratiolet, M., on aphasia, 678 ; on cerebral convolutions, 658 *note ;* on cerebrum, 663.
Graves, Dr., on limit of confusion in touch, 700.
Gray, Mr. H., on structure and development of spleen, 207, 209 ; on blood of splenic veins, 264.
Green, Dr., on protracted lactation, 976.
Gregory, Dr., his case of suggested dreaming, 692 *note*.
Gréhant, on gases of blood, 259 ; on vital capacity of chest, 366 ; on amount of tidal air, 367 ; on urea in blood, 479, 480.
Grenacher, on muscle, 784 *note*.
Grey substance of spinal cord, 566.
Griffith, Mr., on the composition of milk, 974.
Grohe, on ferment in lymph, 202 ; on spermatozoa, 870 *note*.
Groner, on formation of fat, 413.
Groves, Prof., on the correlation of the physical forces, 13 *note*.
Growth, period of, 1013 ; importance of heat for, 5 ; a source of demand for nutrition, 396 ; excess and deficiency of, 422, 425 ; its difference from development, 398 ; formative activity during period of, 1012 ; rate of, 963.
Gruber, on starch, 84.
Gruby and Delafond, MM., on cells of intestinal villi, 181.
Grünewaldt and Schroeder, on quantity of gastric fluid, 146.
Grunmach, on rate of motion of pulse wave, 316 ; on muscle, 784 *note*.
Grützner, on pepsin, 147 ; on succus entericus, 167 ; on vaso-motor nerves, 308 ; on respiration with deficiency of oxygen, 387 ; on chemistry of contracted muscle, 793 ; on nerve stimuli, 548, 564.
Gscheidlen, on quantity of blood, 223 ; on vaso-motor centre, 308 ; on origin of urea, 480 ; on albuminuria, 463 ; on reaction of nerves, 530, 549, 790 ; on muscle, 783 *note ;* on spontaneous generation, 965 *note ;* on lactose, 973 *note*.
Guachos, their meat diet, 95.
Guanin, 78.
Gübler, on relation between colouring matters of blood and bile, 442 *note*.
Guiding sensations, 117, 637, 812 ; essential to regulation of certain movements, as to those of the eye, 817 ; those of the larynx, 832.
Guillot, M., on amount of milk secreted, 978 *note*.
Guinea-pig, time required to produce asphyxia in, 388.
Guislain, M., on influence of emotions on nutrition, 862.
Gull, Sir W., on uses of plexuses of nerves, 542 *note*.
Gulliver, Mr., on molecular base of chyle, 202, 203 ; on spleen, 209 ; on adrenals, 212 ; on thymus gland, 214 ; on red corpuscles of blood, 226, 227 ; on coagulation of blood, 242–251 ; on elasticity of lungs, 348 ; on temperature of cold-blooded vertebrates, 498 ; on post-mortem rigidity, 810 ; on fatty degeneration of arteries, 420 *note ;* on disappearance of spermatozoa in disease, 871, 872 *note ;* on climacteric disease, 1027 *note*.
Gum, effects of diet of, 93.
—— sugar, 82.
Gundlach, on formation of fat, 413.
Gunning, on vaso-motor centre, 307.
Günther, on gangliated cord of articulata, 572.
Gussenbauer, on the muscular fibres in the cardiac valves, 274.
Gustatory nerves, 591, 708 ; mode of termination of, 711.
———— organs, 711.
———— pore, 711.
———— cells, 711.
Guttmann, on action of potassium bromide on heart, 298 *note*.
Guy, on influence of sex on pulse, 301 ; on influence of muscular exertion on pulse, 301.
Gwosdew, on blood crystals, 239.

HABIT, influence of, in establishing excito-motor actions, 615 ; on impressions on sleeping persons, 687 ; on amount of sleep required, 688, 689 ; on co-ordination of muscular movements, 812, 820 ; on skull, 990.
Hachisch, effects of, 691.
Hadlich, on cerebellum, 645 *note*.
Haeckel, on protista, 37 ; on general morphology, 32.
Hæmadromometer, 323.
Hæmadynamometer, 320.
Hæmatin, 235, 237 ; effect of nitric acid on, 442 *note ;* in urine, 469.
Hæmatoblasts, 226, 253.
Hæmatochometer, 324.
Hæmato-crystallin, 67.
Hæmatocytometer, 226.
Hæmatoidin, 238, 441.
Hæmatoin, 238.
Hæmatolin, 238.
Hæmatoporphyrin, 238.
Hæmaturia produced by injection of glycogen, 454.
Hæmin crystals of blood, 237.
Hæmochromogen, 237.
Hæmoglobin, 235, 236, 804 *note*.
———— spectrum, 241.
Haeser, vital capacity of Germans, 366.
Hafiz, on trophic nerves, 308, 858 *note*.
Haidlen, on milk, 974 *note*.
Haighton, on nerve regeneration, 528 *note*.
Hair, characters of, in different races, 986.
Hake, on nuclein, 73.
Hales, on absorption, 205 ; on dynamics of circulation, 318 ; on the force of the heart's contraction, 319 ; on rate of blood's movement in capillaries, 329.

Halford, Prof. G. B., on the movements and sounds of the heart, 277, 284, 307.
Hall, Dr. C. Radclyffe, on vital capacity of lungs, 367 ; on ciliary ganglion, 586 *note*.
Hall, Dr. J. C., on protracted gestation, 121; on lactation by male, 969 *note*.
Hall, Dr. M., on deglutition, 121 ; on circulation in acardiac fœtus, 330 *note;* on intercostal muscles, 352 ; on stimulus to respiratory movement, 362 ; his mode of artificial respiration, 390 *note;* on reflex action of spinal cord, 606, 612 ; on muscular tension, 616 ; on articulate sounds, 843 *note;* on stammering, 843; on function of nerve trunks, 546 ; on teething, 1017.
Haller, on irritability of muscle, 806 ; on heat, 878 ; on quantity of blood in the body, 222 ; on relative capacity of cardiac ventricles, 273 ; on rapidity of muscular movements, 821, 826 ; on respiratory pulse, 360 ; on vicarious secretion of urine, 431; on closure of pupil, 736 ; on heart, 276.
Hallwachs, on hippuric acid, 477.
Halones of vitellus, 910.
Hamberger, on action of intercostals, 352.
Hammarsten, on lymph, 202 ; on tension of carbonic acid in blood and lymph, 380; on flow of lymph, 333 ; on milk, 971.
Hammond, Dr., on diet of gum, 93 ; on diet of albumen, 94, 409, 462; on effects of alcohol, 107 ; on effects of tobacco, 109 ; on blood corpuscles, 226 ; on action of carroval on heart, 297 *note;* on condition of circulation in brain during sleep, 339 ; on urine, 467, 475; on muscle, 825.
Hämpeln, on albuminuria, 463 *note*.
Hand of man, peculiar attributes of, 17.
Hankel, M., on velocity of sensory impulses, 553.
Hannover, Dr., on exhalation of carbonic acid, 374 ; on optic chiasma, 623.
Haptogen membrane, 64.
Harless, Dr., on muscular contraction, 792 *note;* on effect of withdrawal of water from nerves, 550 ; on effect of ether on motor nerves and on muscles, 804.
Harley, Dr. G., on quantity of gastric juice, 146 ; on effects of ablation of adrenals, 212 ; on glycogeny, 448, 454; on excretion of urea, 480; on superfœtation, 902 *note;* on effect of poisons on the blood, 809.
Harmony of muscular movements, 817.
Haro, on rate of movement of blood in capillaries, 329.
Hartig, on aleuron, 74.
Harting, on the pneumogastric nerve, 123 *note*.
Harvey, Dr. Alex., on relative influence of male and female parents, 902, 905 *note;* on influence of fœtal blood on maternal, 906 *note*.
Harvey, William, influence of a single coitus, 886 *note*.
Hassall, on thymus, 215.
Hasse, on spleen, 207; on structure of ear, 764 *note*.
Hastings, Dr., on animal heat, 501.
Haughton, Prof. S., on work done by heart, 285 ; on work done by muscles of respiration, 355 ; on amount of work done in and by the body, 417 ; on excretion of urea, 471, 472, 473, 475 ; on the sound accompanying muscular contraction, 794 ; on the contractile energy of muscle, 822, 825 *note*.
Haversian canals of bone, 48.
Hayem, on blood corpuscles, 226, 253, 266.
Haygarth, Dr., on metallic tractors, 863 *note*.
Head kidney, 936.
Hearing, organ of—functions and structure of membrana tympani, 769 ; of intrinsic muscles, 770 ; of ossicula auditûs, 770, 771 *note;* of tympanic cavity, 771 ; of Eustachian tube, 771 ; course of vibrations through, 771 ; of labyrinth, 773 ; endolymph, 773 ; perilymph, 773 ; otoconia, 773 ; otoliths, 773 ; semicircular canals, 773 ; cochlea, 774 ; organ of Corti, 774 ; its essential structure, 763 ; its adaptation to laws of propagation of sounds, 768 ; structure and functions of tympanic apparatus, 769 ; of labyrinth, 773 ; of external ear and meatus, 775 ; nerves of, 623 ; centre for, 675.
Sense of, 835 ; discrimination of pitch of tones, 774; estimate of direction of sounds, 773, 776; estimate of distance, 776 ; influence of habitual attention on acuteness of, 776 ; rapidity of perception by, compared with vision, 777, 778; use of, in regulating voice, 778 ; sense of, Kinetic theory, 774; estimation of quality, 774 ; of tones, 774 ; on deaf spots, 775 ; on inability to appreciate sounds, 774; estimation of intensity, 777 ; on sense of time in the ear, 777 *note;* on the accommodation of the ear, 777 *note;* appreciation of, in relation to Fechner's formula, 779 ; harmony of muscular movements by means of, 817 ; physical conditions of, 759.
Heart, general functions of, 271 ; comparison of right with left auricle, 273; ventricle, 273; valves of, 273 ; muscular fibres of, 272, 274; arrangement of muscular fibres in, 272; capacity of cavities, 273; irritability of, 275 ; rhythmical movements of, 277; time of, 277; movements of, 277; rate of, 277; action of, 275; effect of ligature of coronary arteries of, 275 ; intracardiac pressure, 276 ; cause of contraction, 276; apex of, 276; systolic and diastolic pressure in, 276 ; influence of irritability on rhythm, 277; account of one cardiac revolution, 279; impulse of, 279 ; action of valves of, 280 ; relative size of orifices in, 281 ; venous pulse, cause of, 281 ; influence of respiration upon, 281; rapidity of circulation, 299 ; varying excitability of, 288 ; latent period of, 288, 292; effect of temperature on, 288 ; heat

diastole, 289 ; independent action of, 285 ; effects of increased pressure on, 291 ; inhibition of, 806 ; cardiograph, 282 ; causes of impulse, 283 ; force exerted by, 285 ; course of blood through, 280 ; sounds of, 283 ; influence of nervous system on, 285, 848 ; excito-motor system of, 276, 285 ; effects of temperature on, 289 ; effect of various poisons on, 276, 287, 293, 297 ; effects of electrical currents on, 287 ; nerves, inhibitory, 291 ; nervus depressor, 294 ; nerves, 298 ; quantity of blood expelled by, 299 ; accelerating, 295 ; influence of shock on, 295 ; action of poisons on, 276, 298 ; number of beats, circumstances affecting, 300–301 ; influence of, on respiratory movements, 353 ; peculiarity in contractions of, 789, 793 ; development of, in muscular contraction, 793 ; number of pulsations of, 825 ; first development of, 918, 923 ; subsequent changes in, 923, 927–931.

Heat centres, 504, 506.
—— diastole, 289.
—— dyspnœa, 507.
—— asphyxia, 509.
—— rigor, 289, 810.
—— tetanus, 802.
—— units produced daily, 417.
—— expenditure of, 514 ; influence of drugs upon, 516 ; effect of, on heart, 288 ; power of generating, 517 ; importance of, in growth and development, 4, 5, 1016 ; influence of, on vital action, 497 ; on period of gestation, 980 ; endurance of extremes of, 506 ; its production in human body, 508, 509, 514 ; sources of variation of, 499, 501, 507, 511 ; alterations of, in disease, 504, 516 *note ;* liberation of, after death, 498, 501, 505 ; sources of, 510, 513 ; loss of, the cause of death by starvation and exhausting diseases, 511, 1031 ; partial dependence of, on cutaneous respiration, 495, 507, 511 ; absolute amount of, produced in the body, 499, 503, 514, 515 ; influence of nervous system on, 503, 507 ; local variations of, 504, 509 *note*, 515, 516 ; inferior power of generating, at earliest and latest periods of life, 499, 500, 509, 517 ; influence of, on secretion of sweat, 493 ; influence of, on elimination of carbonic acid, 370 ; inspiration, tetanus from, 361.

Heaton, Mr., on seat of oxidizing processes, 418, 825 *note*.

Heiberg, on regeneration of corneal epithelium, 427.

Heidenhain and Brücke, on reaction of nerve, 530 ; on spinal accessory, 593.

Heidenhain, Prof., on cells of salivary glands, 429 ; on gastric juice, 146 ; on villi, 181 ; on temperature of heart, 224 ; on gases of blood, 260 ; on action of curare on heart, 298 *note ;* on vaso-motor centre, 308 ; on structure of liver, 436 ; on pressure of bile, 440 ; on action of nerves on liver, 446 ; on kidney, 457 *note*, 458, 461 ; on temperature of brain, 498 ; on animal heat, 504 *note*, 516 *note ;* on law of muscular contraction, 562 ; on muscles, 798 ; his tetano-motor, 549, 801 ; on vaso-motor nerves, 852 *note ;* on temperature of nerves, 551 ; on respiration of imperfectly oxygenated air, 387.

Height at different ages, 964.

Heinemann, M., on action of strychnia on heart, 298 *note*.

Heintz, on kreatin and kreatinin, 477 ; on milk, 977.

Heinzmann, on thermic excitation of nerves, 549 *note*.

Heitzmann, on effects of ingestion of lactic acid, 50 *note*.

Helger, on inosit, 85.

Helicine arteries, 340.

Helleborus niger and viridis, action of, on heart, 297.

Heller, on migration of white corpuscles, 331 ; on urine in disease, 475 ; on blood-vessels of villi, 179.

Hellerworden, on origin of urea, 479.

Helmholtz, Prof. H., on conservation of energy, 13 *note ;* on muscular force of heart, 285 ; on calorification, 417 ; on absolute amount of heat produced in body, 514 ; on rapidity of transmission of motor impulses, 551, 553 ; on accommodation of the eye, 722 ; on optical constants, 724 *note ;* on the horopter, 740 ; his theory of acoustics, 760, 841 ; on membrana tympani, 769 ; on function of cochlea, 774 ; on period of latent excitation, 797 ; on chemical changes and rise of temperature during muscular contraction, 793 ; during action of nerves, 551 ; on volitional movements of the eye, 819 ; on vision, 719, 733 ; on colours, 749 ; on complementary colours, 751.

Helmont, Van, on muscles of respiration, 353.

Helps, Mr., on post-mortem movements in cholera patients, 809.

Helvetius, on vicarious secretion of urine, 432.

Hemi-albumose, 149.

Henderson, on respiration of various gases, 385.

Henke, M., on ossicula auditûs, 772 *note ;* on absolute muscle force, 822.

Henle, Prof., on gastric glands, 145 ; on adrenals, 212 ; on thyroid, 216 ; on kidney, 437 ; on neuroglia, 568, 661 ; on helicine arteries, 340 *note ;* on nerves of taste, 709 ; on cardiac nerves, 274 ; on medulla oblongata, 573 *note ;* looped tubes of, 457 ; on development of spermatozoa, 871 *note ;* on their absence in disease, 872.

Henneberg, on elimination of carbonic acid, 373.

Henneberg and Stohmann, on nutrition, 402.

Hennig, on structure of nerve fibres, 523 *note*.

Hénocque, M., on muscle, 784 *note*.

Henry and Chevallier, MM., on the composition of milk, 974.

Henry, Mr. Mitchell, his case of deficient commissures, 677.

Hensen, on influence of nervous system on glycogeny, 452.
Hensen and Schmidekan, on hearing, 772 *note*.
Hensen, M., on glycogeny, 448, 451, 452; on auditory hairs of crustacea, 762; on waves in ear, 775; on muscle, 784 *note;* cells of, 765; on notochord, 944; on development, 914.
Hensley, Dr., on heart, 272.
Hepatic artery, 434; size of, compared with splenic and renal, 434.
——— duct, 436.
——— parenchyma, arrangement of, 434.
——— vein, 434, 435; blood of, compared with portal, 262.
Hepatin, 449 (see *Glycogeny*).
Heppner, on structure of muscle, 785 *note*.
Herapath, Dr. W. B., on lead-poisoning, 106.
Herbivorous animals, gastric juice of, 150.
Herbst, on quantity of blood, 221; on amount of tidal air, 367.
Hereditary transmission of maladies, 903.
Hering, on pigment cells, 39; on action of fifth nerve on heart, 294; on quantity of blood expelled by ventricles, 299, 300, 335; on vaso-motor centre, 309; on Traube's curves, 310; his experiments on the circulation, 335; on secretion, 429; on nerves of liver, 439; on biliary ducts, 436, 437; on optical illusion of Zollner, 748.
Hermann, Dr. L., on vomiting, 125; on splenic blood, 219; on fibrin ferment, 245; on gases of blood, 260 *note;* on action of intercostals, 352; on poisonous gases, 385; on influence of nervous system on quantity of urine, 465 *note;* on electrical phenomena in nerves, 554 *note*, 563; on electrotonus, 555, 560 *note* 564 *note*, 790, 822 *note;* on electric stimulation of cerebrum, 674 *note;* on muscle force, 825; on limits of audible sounds, 760 *note;* on electrical current in muscle, 797; on muscle, 799 *note;* on rigor mortis, 810; on sympathetic, 847 *note;* on trophic nerves, 855.
Hermaphrodism, 943.
Hermite (L'), M., his osmotic experiment with a fluid septum, 187.
Herschel, Sir J., on spectrum analysis of blood, 239; on light, 754 *note*.
Hertwig, M., on removal of cerebrum, 625, 646 *note;* on cerebellum, 627, 647 *note;* on segmentation of ova, 911.
Herter, on effects of deficiency of oxygen in air breathed, 359, 386; on respiration of oxygen, 385.
Herzen, on ablation of spleen, 220.
Heterogenesis, theory of, 865.
Heubel, on lymph, 210.
Heuzinger, on spontaneous generation, 865 *note*.
Hewett, F. C., on vital capacity, 367.
Hewson, on red corpuscles of blood, 227; on production of red corpuscles in spleen and thymus, 218; on coagulation of blood, 242–251.
Heymann, on excentric vision, 756.
Heynsius, on pigments of bile and urine, 477; on source of urea, 480.
Hibernants (see *Hybernation*).
Hiccup, act of, 364.
Hildebrand, on action of electricity on heart, 287.
Hildersheim, on quantity of fæces, 406.
Hiller, on organisms in blood, 269 *note*.
Hill, Sir G., on cutaneous absorption, 190.
Hilston, on ammonia in snake-bites, 289.
Hilton, on cerebro-spinal fluid, 665 *note;* on spinal accessory, 593 *note;* on trophic nerves, 854.
Hindbrain, 954.
Hindostan, languages and people of, 999, 1002, 1003.
Hinton, on resonance of voice, 771.
Hippel, Von, on trophic nerves, 858.
Hippocrates, on rest, 878; on female semen, 880 *note*.
Hippuric acid, 79, 441; its presence in urine, 468, 469, 476.
Hirsch, on rapidity of transmission of sensory impressions, 553.
Hirschmann, M., on gases of blood, 258, 343; on structure of lung tissue, 346.
Hirt, on the relative proportion of white and red corpuscles in the blood, 233; in splenic blood, 219; in blood of splenic vein, 264.
His, M., on structure of lymphatic glands, 194, 195; on corpus luteum, 883 *note;* on development, 886 *note*, 907 *note*, 910; on development of chick, 920 *note;* on lymphatics of nervous system, 569.
Hitzig, on lesion of crus cerebri, 631 *note;* on cerebellum, 649 *note;* on electrical excitation of cerebral convolutions, 670, 673, 676.
Hjelt-Otto, M., on regeneration of nerves, 528 *note*.
Hofacker, on proportion of sexes, 961.
Hofmann, on composition of cartilage, 46; on peptones, 148; on formation of fat, 413; on elimination of urea, 470 *note*.
Hoffmann, M., on regeneration of epithelium, 427; on glycogen particles in liver, 438 *note*.
Högyes, on sound, 760.
Holland, Sir H., on sleep, 685; on instinctive choice of food, &c., 713 *note;* on influence of expectant attention on involuntary movements, 853; on hereditary diseases, 903 *note;* on temperature of infants, 499.
Holm, M., on adrenals, 212, 213.
Holmes, on action of ergot on heart, 298 *note*.
Holmgren, M., on colour-blindness, 754; on action of light in producing electrical disturbance, 756; on colour sensations, 751 *note*.
Holoblastic ova, 911.
Home, Dr. F., on temperature in disease, 505.
Homolle, M., on absorption by skin, 191.
Homologies of sexua organs, 942.

Honigschmied, on sense of taste, 711 *note.*
Hooker, Dr., on relation between pulse and respiration, 356 *note.*
Hooker, Sir J. D., on the theory of continuous development, 980; on the flora and fauna of New Zealand and Australia, 1008 *note.*
Hoppe, Dr. F., on spectrum analysis of blood, 239; on effects of breahing a highly rarefied atmosphere, 376; on formation of fat, 414.
Hoppe-Seyler, on composition of cartilage, 46; on fermentation, 64, 67; on lecithin, 82; on cholesterin, 88; on pancreatic digestion, 163; on proportion of corpuscles to plasma in blood, 230 *note;* on hæmoglobin, 237, 241; on formation of fibrin, 244; on composition of blood, 253; on gases of blood, 259, 343; on fibrin, 277; on respiration of poisonous gases, 339; on glycogeny, 450; on composition of liquor amnii, 926 *note;* on milk, 974 *note.*
Horbaczewski, J., on auditory nerve, 763.
Horopter, nature of, 740.
Horvath, influence of external cold upon temperature, 503; on animal heat, 516; on anæsthesia by cold, 705.
Hospitals, composition of air in, 393.
Hottentot race, 1006.
Houckgeest V. Braam, on intestinal movements, 122, 128.
Houston, Dr., on circulation in acardiac fœtus, 330 *note.*
Howe, Dr., on education of Laura Bridgman, 31; on idiotcy, 904 *note.*
Howship, on lacunæ of bone, 419.
Hoyer, on pigment-cells, 39; on development of lymph corpuscles, 218; on the olfactory nerves, 715 *note.*
Hoyle, on consumption of alcohol, 106.
Hübbenet, on pancreatic juice, 162.
Hüber, on formation of fat, 413.
Hüfner, on ferments, 69; on gases of intestine, 175; on hæmoglobin, 237; on kidney, referred-to, 457 *note,* 458.
Huguier, M., on Duverney's glands, 880 *note.*
Huhnefeldt, on gastric juice, 146.
Humboldt, Von, case of lactation by male, 969 *note.*
Humus, absorption of, by plants, 7.
Hunger, indicates necessity for aliment, 110; immediate source of sense of, 110.
Hunter, John, on coagulation of blood, 243, 249; on elasticity of arteries, 305; on retardation of blood by curves in vessels, 317; on heart's impulse, 279; on temperature in disease, 505; his case of paraplegia, 607 *note;* on post-mortem rigidity, 810; on vesiculæ seminales, 869.
Hüppel and Grünhagen, on intra-ocular pressure, 719 *note.*
Hüppert, on glycogeny, 456 *note.*
Huss, Dr., on chronic alcoholism, 108 *note,* 421 *note.*
Hutchinson, Col., on ancon breed of sheep, 993 *note.*
Hutchinson, Dr. J., on elastic tension of lungs, 348; on action of intercostal muscles, 352; on forces of inspiration and expiration, 354; on vital capacity of chest, 355; its relation to height and weight, 355; on amount of air inspired, 355, 366; on asphyxia, 388; his case of lost sense of smell, 713 *note;* on change of colour in negro, 713 *note,* 985 *note.*
Hutchinson, Mr. Jon., his cases of nerve lesion, 504; on nerve lesions, 855 *note.*
Huxley, Mr. T. H., on agamic development of aphis, 5; on cranium of man, 21–26; on fossil remains of man, 29 *note;* on the zoological relation of man with the lower animals, 26 *et seq.;* on structure of spleen, 207; on tactile papillæ, 699 *note;* on muscular fibre, 785 *note;* on the development of the ovum in pyrosoma, 885 *note;* on development of embryo, 910 *note;* on the Neanderthal cranium, 982; on leiotrichi, 986; on skull in various races, 987 *note;* on ossification of temporal, 950.
Hyalin cartilage, 45.
Hybernation, effects of, on blood, 225, 261.
Hybrid races, question of fertility of, 995.
Hybrids, influence of parents on, 902.
Hydrobilirubin, 238, 478.
Hydrocarbonaceous compounds, 82.
Hydrochloric acid gas, effects of breathing, 359.
Hydrocyanic acid gas, action of, on heart, 297 *note;* effects of respiration of, 359.
Hydrogen, elimination of, by lungs, 369, 383; per diem, 404; respiration in, 359, 378.
——— arsenide, effects of respiration of, 385.
——— cyanide, effects of respiration of, 385.
——— phosphide, effects of respiration of, 385.
Hydroid polypes, structure of, 781.
Hydrophyr, 149.
Hygrometric conditions of air, influence on respiration, 370.
Hyocholalic acid, 441 *note.*
Hyoid arch, 949.
Hyoscyamin, action of, on heart, 297 *note.*
Hyperæsthesia, 601, 609, 612, 695.
Hypermetropia, 725.
Hypertrophy, 397, 423; conditions of, 422.
Hypnotism, 686, 692, 863.
Hypoblast, 914; structures derived from, 915.
Hypochondriasis, operation of, 864.
Hypogastric plexus of sympathetic, 846.
Hypoglossal nerve, origin of, 578, 594; union of, with lingual, 544; functions and distribution of, 596; number of, 595; fibres in, 594.
Hypospadias, 943.
Hypoxanthin, 78, 461.
Hyrtl, on cause of heart contraction, 277 *note.*

I'ANSON, on nerve lesions, 855 *note*.
Icelanders, freedom of, from tuberculosis, 99.
Idea, cause of, 538, 539, 540, 640, 681, 683.
Idiocy, predominance of instinct in, 669; causes of, 904; weight of brain in, 664.
Idio-muscular contraction, 801.
Impregnation, changes effected by, in ovum, 885; position of, 886.
Inanition, 109; balance of vital economy in, 406; effects of, on temperature, 510.
Indican, 76, 468, 478.
Indigo, 76.
—— blue, 76.
—— glucin, 76.
—— rubin, 76.
Indo-European race, 998.
Indo-Germanic languages, 999.
Indol, 67, 76, 77.
Inée (poisoned), action of, on heart, 298.
Infancy, characteristics of, 1015.
Infants, temperature of, 499; inferior power of generating heat in, 509; length and weight of, at birth, 1015.
Inferior laryngeal nerve, influence of, on respiration, 360.
Infundibula of lungs, 345.
Ingesta, average chemical composition of, for one day, 404, 405.
Inhibition of respiration, 361.
Inhibitory influence of the nervous system on intestine, 128; on heart, 290, 292; on vessels, 310; on respiratory muscles, 361; on reflex actions, 606.
Inman, Dr., change of colour in negro, 985 *note*.
Inoblast, 457.
Inorganic constituents of body, 80; of blood, 251; their uses, 415; of urine, 523, 524, 537.
Inosit, 461; in urine, 469; in nerve, 530.
Inosinic acid, 412.
Insalivation, 132.
Insects, automatic actions of, 532; rapidity of, 826.
Inspiration, effects of, on blood pressure, 322; movements of, 350; muscles of, 352; force required for, 354.
Inspiration-tetanus, from application of heat to vagi, 361.
Inspiratory muscles, 352; power of, 355.
Instinct, contrasted with reason, 667.
Instruments, relation of voice to, 833.
Intelligence, 538; nature of, as opposed to instinct, 532; degree of, conformable to size and development of cerebrum, 668; relation of, to cerebro-spinal system, 540; in brutes, 666 *note*.
Interannular segments, 524.
Inter-carotidean gland, 217.
Interference action of vagi, 295.
Interlaminar plexus of lymphatics of intestine, 179.
Interlobular veins, 435.
Intermediary lamellæ of bone, 48.
Internuncial fibres, 530.
Intestinal canal, movements of, 116; influence of sympathetic nerves on, 128; development of, 931.
———— ferment, 69.
———— juice, 169; its use in digestion, 169; quantity of, 403.
———— secretions, influence of nervous system on, 853.
Intra-cartilaginous ossification, 51.
Intra-lobular veins, 435.
Intra-membranous ossification, 52.
Intra-nuclear fibres, 34, 35.
Inulin, action of pancreatic juice on, 161.
Inversive ferments, 69.
Investing spaces of lymphatic glands, 195.
Involuntary movements, 811; influence of sympathetic on, 849; muscle, 782.
Inzani and Lussana, on nerves of taste, 708 *note*.
Ipecacuanha, effects of, 125.
Iris, structure of, 734; movements of, in accommodation of eye, 722, 723; effects of heat and light upon, 734 (see *Pupil*); blood supply of, 734; nerves of, 735.
Irminger, M., on biliary ducts, 437, 495; perivascular lymphatics in liver, 439.
Iron in body, 92.
Irradiation of impressions on retina, 752, 756; reflex in cord, 605.
Irrigation of the tissues effected by lymph, 205.
Isaacs, on kidneys, 457 *note*, 459 *note*.
Isatin, 77.
Isatyd, 77.
Isolactic acid, 86.
Izquierdo, on tactile corpuscles, 699.

JAAGER, M. de, on rapidity of transmission of impulses through motor nerves, 553.
Jaborandi, action of, on heart, 293.
Jaccoud, on uses of salt, 91.
Jackson, Dr. J. H., on choreic movements, 602 *note*; on thalami optici, 629; on cerebellum, 649 *note*; on agraphia and aphasia, 678; on the condition of the circulation in the retina during sleep, 782; on training diet, 104.
Jackson, Dr., on vital capacity of lungs, 366 *note*; on gradual death in adynamic fevers, 1029 *note*.
Jacob's membrane, 729.
Jacobson, M., on temperature of blood, 224; on pressure of blood in veins, 361 *note*; on temperature in inflamed parts, 505; on effects of curare on animal heat, 517; on liver ferment, 441; on renal portal system, 444.
Jaffe, M., on hippuric acid, 79; on stercobilin, 173; on urobilin, 442 *note*, 478; on glycogen in brain, 450.
Jago, James, on tympanic cavity, 771.
Jaminet, M., on action of compressed air, 303, 375.
Jardine, Rev. Fergus, case of, 899 *note*.

Jaundice, bile in the tissues in, 433.
Jaw, development of lower, 951; development of upper, 951.
Jeaffreson, Mr., on Daltonism, 754 *note*.
Jeffreys, Mr. J., on inspired air, 365, 368 *note;* on Daltonism, 754.
Jelenffy, on crico-thyroid muscle, 828 *note*.
Jendrassik, on thymus gland, 213; on muscle, 799 *note*.
Jewish females, period of conception in, 884 *note*.
——— nation, 1001; varied complexion of, 985.
Jobelin, on intercostal muscles, 353.
Jobert, M., on corpuscula tactûs, 699 *note*.
Johnson, Dr. G., on structure of kidney, 456 *note;* on albuminuria, 462, 463 *note*.
Johnston, Dr., on cause of summer diarrhœa, 67.
Johnston, Crosse, influence of climate upon temperature, 499 *note*.
Johnstone, Dr., on conversation of deaf and dumb, 839.
Jolly, M., on intra-cranial pressure, 339.
Joly and Filhol, MM., on the composition of milk, 974.
Jones, Dr. Bence, on animal quinoidin, 81; on rapidity of absorption by stomach, 183; on sulphates in urine, 481; on phosphates in urine, 482; on acidity of urine, 476, 484; on alkalescence of urine, 485.
Jones, Dr. Handfield, on fatty degeneration, 420 *note*.
Jones, Dr., on condition of prisoners in Fort Sumter, 114.
Jones, Mr. Wharton, on lymphatic heart of eel, 204; on development of red corpuscles, 253; on white corpuscles, 233; on rhythmical movements of veins in bat's wing, 335; on structure of spleen, 207.
Joseph, on trophic nerves, 856.
Joule, mechanical equivalent of heat, 514 *note*.
Jousset, on employment of trachea for absorption, 387.
Jurasz, on action of bile and urea on blood-corpuscles, 227.
Jürgessen, Dr., on temperature of the body, 500, 502, 508.
Jurin, Dr., on absorption of vapour, 190.
Juzani, on chorda tympani, 624 *note*.

KAFFRE race, 1005; language of, 1005.
Kahler, on cerebral lesions, 677 *note*.
Kaiser, on the horopter, 740 *note*.
Kammler and Aubert, on sense of weight, 703.
Kapff, on ovaries, 874 *note*.
Kassowitz, on trophic nerves, 857 *note*.
Kaster, on evolution of light by body, 520.
Kathelectrotonus, 558, 559, 563.
Kauffmann and Rosenthal, MM., on action of sulphuretted hydrogen on heart, 298 *note*.
Kaupp, on quantity of urine, 465 *note;* on excretion of urea, 474.
Kehrer, on milk, 972.
Kellie, Dr., on the intra-cranial circulation, 338.
Kemmerich, on value of salts in beef-tea, 95; on formation of fat, 414; on composition of milk, 971, 977.
Kempelen, on vocal sounds, 832, 840, 841.
Kendall and Luchsinger, on nervous mechanism of secretion of sweat, 491–492.
Keratin, 71; membrane in nerve, 526.
Kering, on regulating mechanism for heat, 508.
Keuchel, on inhibition of heart's action, 290 *note*.
Key and Retzius, on structure of nerve fibres, 523.
Kidd, P., on movements of nucleus, 35 *note;* on development, 914.
Kidney, quantity of blood passing through, 460; chemical composition of, 461; nerves of, 461; morbid changes in, 461, 495; structure of, 457; tubuli uriniferi of, 457; circulation in, 459; corpora Malpighiana of, 457; secreting cells of, 457, 460; elimination of water by, 460; of soluble matters generally, 481; two factors occasioning secreting action of, 479, 486; excretory function of, 456–489; development of, 936; lymphatics of, 461 (see *Urine*).
Kiernan, Mr., on structure of liver, 435, 443.
Kilian, on fatty degeneration of uterus after parturition, 420.
Kinesodic substance, 598 *note*.
Kinetic theory of hearing, 774.
King, Mr. T. W., on tricuspid valve, 280, 281.
Kingzett, on nuclein, 73.
Kinic acid, 477.
Kirkes, Dr., on effects of disease of adrenals, 213; on sympathetic, 850.
Kishu, on visual purple, 730 *note*.
Kistiakowski, on pancreatic peptones, 163.
Kitchen-middings, 983.
Kitto, Dr., on guiding sensations, 638; his cases of acute tactile sensibility, 707.
Klaatsch, seat of sense of taste, 712.
Klebs, on absorption of insoluble substances, 185; on structure of nerves, 525 *note*.
Klein, on lymphatic system, 193; on Peyer's patches, 198; on spleen, 207, 209; on capillaries, 326; on non-medullated nerve fibres, 327; on structure of nucleus, 35; on nerves of intestine, 126; on gastric glands, 142; on lymphatic system, 192 *note*; on structure of testes, 867 *note;* on development of spermatozoa, 871; on ovaries, 874 *note;* on serous membranes, 196; on thymus, 214; on action of reagents on blood, 227; on white corpuscles, 233; on development of blood-vessels, 252, 923; on primordial ova, 939; on corpuscula tactûs, 699 *note;* on nerves

of capillaries, 327 ; on lymphatics of lungs, 347 ; on nerve-endings in cornea, 526 ; on organisms in blood, 269 *note ;* on structure of nerve fibres, 523 ; on ciliary movement, 781 *note.*
Klein and Noble Smith, on cells of villi, 182 ; on proportion of plasma and corpuscles in blood, 225 ; on arteries, 305 ; on capillaries, 327 ; on nerves of uterus, 894 *note.*
Kleinenberg, on neuro-muscular cells, 782.
Kletzinsky, on urine, 469, 478 *note.*
Klug, on sense of touch, 701 *note.*
Klünder, on muscular contraction, 798.
Klupfel, on acids of urine, 482.
Knapp, on lens, 720 ; on accommodation of the eye, 722.
Knieriem, on origin of urea, 479 *note.*
Knoll, on inhibition of respiration through olfactory nerve, 361 ; on effects of lesion of corpora quadrigemina, 628.
Knorz, M., on absolute muscle force, 822.
Kobelt, Dr., on *emissio seminis*, 873 ; on Fallopian tubes and Wolffian bodies, 937 *note.*
Koch, on cause of splenic fever, 67.
Köhlrausch, M., on rapidity of transmission of impulses through motor nerves, 553.
Kölk, Schroeder van der, on coagulation of blood in vessels, 249 ; on spinal cord, 570 ; on medulla, 573 *note*, 574 ; on crura cerebri, 632 *note.*
Kölliker, Prof., on osteoclasts, 50 ; on splanchnics, 128 ; on structure of gastric follicles, 145 ; on bile capillaries, 437 *note ;* on rate of secretion of bile, 167 ; on muscular structure of intestinal villi, 179 ; on structure of lymphatics, 194 *note ;* on structure of Peyerian glands, 198 ; on structure of spleen, 207 ; on vaso-dilatator fibres, 852 *note ;* on adrenals, 212 ; on thymus, 214 ; on thyroid, 216 ; on proportion of colourless corpuscles to red, 233 ; on action of curare on heart, 298 *note ;* on structure of arterial walls, 305 *note ;* on diameter of capillaries, 327 ; on veins, 333, 340 ; on erectile tissue, 340 ; on lungs, 344 ; on giant cells, 419 ; on starch in test of Tunicata, 447 ; on structure of kidney, 456 *note*, 459 ; on spinal cord, 565 *note*, 573 ; on neuroglia, 568 ; on connection of corpora striata and thalami optici with cerebrum, 619 *note ;* on cerebrum, 661 ; on tactile papillæ, 699 *note ;* on termination of motor nerves, 787 ; on structure of iris, 735 *note ;* on function of retina, 733 ; on cochlear nerve, 764 *note*, 766 ; on action of curare on motor nerves, 803 ; on analysis of semen, 868 *note ;* on evolution of spermatozoa, 871 ; on augmentation of uterine substance in pregnancy, 889, 894 ; on placenta, 891 ; of limbs, 961 *note ;* of muscle, 791 *note ;* of mesoblast, 914 *note*, 916 *note ;* on urea, 471 *note ;* on development, 909 *note ;* on notochord, 944 *note.*
Kollmann, on development of intermaxillary bone, 951.
Konjkoff, effect of foods on glycogen formation, 449 ; effects of arsenic and amyl nitrite, 454.
Körner, M., on temperature of blood in heart, 224 ; on nerves of uterus, 894 *note*, 893 *note.*
Korowin, on pancreatic ferment, 161.
Kossel, composition of peptone, 149.
Koster, M., on absolute muscle force, 822.
Kottenkamp and Ullrich, on cutaneous sensibility, 702 *note.*
Kottmeier and Küthe, MM., on secretion of bile, 443.
Koumiss, 977.
Kowalewsky, on spleen, 207 *note ;* on inhibitory nerves of heart, 290 *note ;* on vaso-motor nerves, 308 ; on variations of arterial pressure, 309, 310 ; on elimination of carbonic acid, 375 ; on respiration of oxygen, 485 ; on bile, 440.
Krahmer, Prof., on action of diuretics, 488.
Kratschmer, on action of fifth on heart, 294 ; on vaso-motor centre, 309 ; on arrest of respiration, 361.
Krause, Prof., on lymph, 200, 206 ; on coccygeal gland, 217 ; on erectile tissue, 340 ; on kidney, 457 *note*, 461 *note ;* on termination of nerves in muscle, 787 ; on sudoriparous glands, 489 *note*, 490, 494 ; on the nerves of touch, 699 *note*, 700 *note ;* on length of muscular fibre, 784 ; on respiratory centres, 568 *note ;* on number of fibres in optic nerve, 732.
Krauss, on structure of retina, 728 *note ;* on structure of muscle, 784.
Kreatin, 77, 461, 469, 477, 480 ; in nerve, 530 ; in muscle, 787.
Kreatinin, 77, 468, 477, 480 ; in muscle, 789.
Kreidmann, on depressor nerve, 309.
Kreitzen, on histology of virgin uterus, 894 *note.*
Kries, on the pressure of blood in capillaries, 330.
Krolow, on digestive action of intestinal glands, 169.
Kronecker and Stirling, on tetanus, 801.
Kronecker, laws of muscular exhaustion, 805.
Kryptophanic acid in urine, 468.
Kühn, on cochlea, 764 *note.*
Kühne, Prof., on casein, 64 ; on fibrin ferment, 245 ; on bile, 445 ; on ciliary movements, 781 *note ;* on blood crystals, 235, 239 ; on glycogeny, 450, 455 ; on hippuric acid, 477 ; on muscle, 784 *note*, 785 ; on mode of termination of motor nerves, 787 ; on effects of stimuli applied to muscle and nerve respectively, 802 ; on albuminous materials in muscle, 438 ; on visual purple, 730, 731 ; on action of reagents on blood, 227 ; on elimination of ammonia by lungs, 383.
Kühnt, on structure of nerve fibres, 523 *note ;* on number of fibres in optic nerve, 733.
Kulz, relations of bile and glycogen secretion, 453.

Kunkel, on rapidity of perception of colour, 752.
Kupffer, on spinal cord, 570 *note;* on cerebrum, 661.
Kupressow, on pressure of urine in bladder, 488.
Kusnezoff, on spleen, 220.
Küss, on arsenic in blood, 256; on lungs, 345; on intercostal muscles, 353; on regeneration of corneal epithelium, 427; on laws of reflex action, 604; on secretion of urine, 466 *note.*
Küssmaul and Tenner, on intra-cranial circulation, 339; on the effects of anæmia on reflex excitability of cord, 605.
Küssner, on formation of urea, 479.
Küthe, on bile, 168.
Küttner, on sympathetic nerve, 846 *note.*
Kyber, on spleen, 207, 210.
Kymograph, 319, 321.

LABORDE, on gastric juice, 146.
Laborde and Leven, on trophic nerves, 854.
Labour, work done in various kinds of, 823.
Labyrinth of ear, functions of, 773.
Lachrymal secretion, influence of mental states on, 858.
Lactation, 966–979; change of quality of milk in course of, 970, 974; extraordinary prolongation of, 975; fever of, 978; by males, 969 *note;* suspended, 970.
Lacteals, origin of, in villi, 177; absorption by, 182; glandulæ of, 195; (see *Chyle*).
Lactic acid, effects of injection of, 50; origin and relations of, 867; presence of, in urine, 469; ferment, 789.
Lactiferous ducts, 967.
Lactoprotein, 61.
Lactose, 84, 973.
Lacunæ of bone, 47.
Ladovsky, on inability to appreciate sounds, 775.
Laennec, relative capacity of cardiac ventricles, 274.
Lafargue, M., on lesion of thalami optici, 630; on corpora striata, 631, 632.
Lalanne, on tactile sensibility, 704.
Lamellæ of bone, 48; intermediary, 48; perimedullary, 48; peripheric, 48.
Lamandé, M., on amount of work performed by the body, 417.
Lamansky, on perception of colour, 752.
Lamina spiralis, structure of, 765.
Laminæ dorsales, 919.
Lancerotte, on optic thalamus, 630.
Landerer, Dr., on urea in sweat, 491.
Landois, on quantity of fæces, 172; on nerves of villi, 179; on dicrotic pulse, 314; on venous murmur, 337; on movements of respiration, 353; on vital capacity, 366; on sweat glands, 490; on rapidity of colour perception, 752; on stimulation of sympathetic, 515; on rate of heart-beat, 278; on fifth nerve, 585; on auditory nerve, 623 *note*; on cerebrum, 673, 676; on influence of drugs on tactile sensibility, 702.
Landolt, on perimetry, 724 *note*, 725; on position of yellow spot, 733.
Landré, on action of curare on animal heat, 517.
Lang, on cutaneous asphyxia, 495.
Langer, on fœtal heart, 931.
Langerhans, on corpuscula tactûs, 699 *note;* on nerves of heart, 275.
Langhans, on blood crystals, 238.
Langley, on secretion, 429.
Language, the expression of ideas, 678.
Languages of different races, deduction from conformity in, 996; American, 1007; Bushman, 1006; Celtic, 999; Euskarian, 999; Hindoo, 1002; Hottentot, 1006 *note;* Indo-Germanic, 999; Kaffre, 1005, 1006 *note;* Malayo-Polynesian, 1009; Negro, 1004; Negrito, 1010; Sanskritic, 999; Syro-Arabian, 1000; Tamulian, 1011; Australian, 1011.
Lankester, Dr., on various diet scales, 98.
Lankester, Prof. E. Ray, on hæmoglobin in heart, 804 *note;* in plasma of blood of invertebrata, 236; on degeneration, 530 *note;* theory of formation of blastoderm, 913 *note.*
Lantermann, on structure of nerves, 523, 525 *note.*
Lapps, race of, 999, 1002.
Laptschinsky, on vitellin, 64.
Larcher, size of ventricle during pregnancy, 273.
Lardacein, 73.
Larrey, Baron, on Syro-Arabian race, 1000.
Laryngeal nerves, 361.
Laryngoscope, appearances seen by, 831.
Larynx, structure of, 825; precise adjustment of muscular actions of, 825; their dependence on guiding sensations, 812; nerves of, 361, 832; production of sounds by, 832; theory of the voice, 836; falsetto notes, 836; muscles of, 828; appearance of, during life, 830, 831; artificial, 834.
Lassaigne, on cerebellum, 652.
Lassar, on the manometry of the lungs, 355.
Latent period of heart, 288, 292.
——— of muscle, 798.
Lateral vision, 756.
Latham, Dr., on scurvy at Millbank, 114.
Latham, Dr. R. G., on varieties of men, 884 *note;* on Negro area, 987 *note;* on Kaffre language, 1005.
Latour, Cagniard de, on tracheal fistula, 838.
Latschenberger, on blood pressure, 322; on rectal digestion, 171.
Laughing, act of, 364.
Laurence, Mr. J. Z., on astigmatism, 727 *note.*
Laurent, on action of hyoscyamin on heart, 298 *note.*
Lavdovsky, on muscular contraction, 792 *note.*
Laveran, on nerve regeneration, 528 *note.*
Lavoisier, on respiration, 374.
Lawes and Gilbert, on constituents of ood 99; on nutrition, 402, 413.
Laycock, Dr., on vicarious secretion of urine, 431; on cerebellum, 651.

Lead, poisoning of water by, 106.
Lealand, on structure of muscle, 785 *note*.
Leaping, 816.
Leared, Dr., on sounds of heart, 284.
Lebert, on Daltonism, 755 *note;* on muscle, 791 *note*, 755 *note*.
Lebon, on inanition, 115.
Lecanu, M., on fat in blood, 268, 421.
Lecithin, 82, 530; action of pancreatic juice on, 161.
Lee, Dr. R., on cardio-motor ganglia, 285 *note;* on nerves of liver, 439; on periodical discharges of ova, 879; on nerves of uterus, 894.
Lee, Mr. H., on the effect of admixture of pus with blood, 248.
Lee, Mr. W., on preventible disease, 394.
Lefort, on glycogeny, 448.
Left-handedness, 817.
Legallois, relative capacity of cardiac ventricles, 273; on animal heat, 503 *note*.
Legg, on vicarious secretion of bile, 432; on glycogeny, 453.
Legros and Dubreuil, on action of poisons on heart, 297 *note*.
Legros and Onimus, on movements of leucocytes, 35; on intestinal movements, 128.
Legros, on dilating nerves, 310, 340, 852.
Legumes, composition of, 97.
Legumin, composition of, 59.
Lehmann, Dr. Julius, on influence of coffee, 109, 486 *note*.
Lehmann, Prof., on quantity of blood, 223; on extractives of blood, 254; on excretion of urea, 471 *note*; on extractives of muscle, 789; on solution of blood-corpuscles, 228; on composition of portal and hepatic venous blood, 436 *note;* on respiration, 370; on formation of fat, 413; on alkaline salts of blood, 268; on gastric juice, 146; on composition of bile, 445; on origin of bile, 447; on glycogeny, 445; on composition of urine, 467, 468, 469, 472; on its acid reaction, 540; on bile acids, 441.
Leigh, on the air of towns, 393.
Leiotrichi, 986.
Lemmens, Marie, case of, 620.
Lemnisci, 582.
Length of limbs compared with that of the vertebral column, 24 *note*.
Lenhossek, on spinal cord, 570 *note*.
Lenticular nucleus, 589, 630; effects of stimulation, 618.
Lepine, M., on act of vomiting, 124.
Lesser, on quantity of lymph, 200.
Letellier, M., on influence of temperature on production of carbonic acid, 370.
Letheby, Dr., on discharge of ovules in menstruation, 879 *note*.
Letzerich, M., on absorptive organs of villi, 181, 182; on nerves of testis, 868.
Leube, on nutrition, 171, 187, 406; on perspiration, 490, 494; on reflex action, 605.
Leucæmia, 218.
Leucin, 75, 163, 412, 461, 469.
Leuckart, Dr., on spermatozoa, 871 *note;* on development of embryo, 910 *note*, 914; on vesicula prostatica, 941.
Leucocytes, 231.
Leucocythæmia, 267.
Leuret and Lassaigne, on gastric juice, 146, 301 *note*.
Leuret and Mitivié, MM., on pulse rate, 301.
Leuret, M., on comparative anatomy of cerebellum, 645 *note;* on comparative size of cerebellum in geldings, &c., 652, 664; on relative weight of encephalon, 664.
Leven, M., on influence of caffein and thein on action of heart, 298 *note*.
Leven and Ollivier, MM., on functions of the cerebellum, 647 *note*, 648.
Lewes, Mr. G. H., on the sensorial power of the spinal cord, 607 *note*.
Lewis, Bevan, on cerebrum, 668 *note*.
Lewis, Dr., on organisms in blood, 269; on spores in air, 428.
Lewis and Clarke, on cerebral convolutions, 659 *note*.
Lewitzky, on temperature of disease, 505 *note*.
Ley, Dr. H., his case of disordered respiration, 357.
Leyden, on animal heat, 505.
Leydig, Dr., on structure of spleen, 207; on cardiac ganglia, 287; on nerves of touch, 699 *note;* on taste-bud, 710 *note;* on visual purple, 730 *note*.
Lichtenfels, on influence of various circumstances on pulse, 301.
Lieberkühn, on development of notochord, 944 *note;* alkali albuminate, 61; follicles of, 169, 199.
Liebermeister, on action of heat on heart, 288 *note;* on regulating mechanism for heat, 508.
Liebig, Dr. G., on exhalation of carbonic acid from muscle, 342; on respiration of tissues, 379.
Liebig, Prof., on action of muscles on oxygen and carbonic acid, 342; on formation of fat, 413; on amount of carbon excreted, 377; on muscle, 790 *note*.
Liebreich, on reaction of nerve tissue, 530.
Liégard, on duration of pregnancy, 900 *note*.
Liegeois, on sense of smell, 715.
Lieutaud, on relative capacity of cardiac ventricles, 273.
Life, nature of, 1; distinguishing features of, 2–5; multiplication of, 3, 4; importance of heat in development of, 5, 6; influence of light upon, 6; final purpose of, in plants, 8; various manifestations of, in animals, 9, 10; in growth, 9; in production of heat, 10; in sensori-motor activity, 11; in development, 11; correlation of the physical forces in the acts of, 13–15; of the blood, 247.
Light, evolution of, from living body, 497,519.
Lightning, death by, effect of, on blood, 270.
Limbs, development of, 961; nature and development of, 1038; attempted reproduction of, in fœtus, 464.

Limits of vision, 733.
Lindenmeyer, on cholesterin, 88.
Lindgren, on nerves of uterus, 894.
Lining, on absorption of vapour, 190.
Lipsky, on cells of villi, 182.
Liquor amnii, 926.
——— sanguinis, 225, 242.
——— folliculi, 940.
——— Cotunnii, 773.
Lister, Prof., on pigment cells, 39, 781; on lactic acid fermentation, 66; on splanchnics, 128; on inhibition of heart's action, 290 *note;* on the coagulation of the blood, 230, 249; on structure of iris, 735 *note;* on milk fermentation, 971 *note.*
Listing, on visible direction, 738 *note.*
Lithic acid, 531 (see *Uric Acid*).
Lithium in blood, 256.
Litzmann, on function of uterus in impregnation, 880.
Liver, ferment, 69; sugar, 84; composition of, 97; structure of, 434; general plan of, in lower animals, 433; in man, 434; arrangement of blood-vessels in, 434; biliary ducts in, 436; parenchyma of, 438; reaction of, 438; lymphatics of, 438 439; development of, 932; double function of, 439; lobes of, 433; gall-bladder, 433; weight of, 433; assimilating action of, 456; production of glycogen and sugar by, 439, 447, 450; effects of drugs on, 447; excretory action of, 455; formation of bile by, 439 (see *Bile*); time of circulation of blood in, 435; perivascular lymphatics of, 439; nerves of, 439; lymphatics of capsule, 439 *note;* urea in, 480.
Liversidge, on pancreatic ferment, 161.
Livingstone, on temperature of Africans, 499.
Lobular veins, 435; plexus, 435.
Lobuli of lungs, 346.
Lochia, 897.
Locke, on visual perception, 738 *note.*
Locomotion, movements of, 614.
Locomotor ataxy, cause of, 598.
Lombard, on animal heat, 501, 516; on temperature of nerves, 551.
Lomikowsky, on cutaneous asphyxia, 495.
London, composition of air in, 393.
Londonderry steamer, case of, 391.
Longet, M., on quantity of gastric juice, 123; on effects of division of the pneumogastrics on stomach, 155; on contractility of bronchial tubes, 347; on intercostal muscles, 352; on albuminuria, 462 *note;* on spinal cord, 575; on lesion of crus cerebri, 631; on roots of pneumogastric, 586; on removal of cerebrum, 625, 626; on functions of corpora quadrigemina, 627; on thalami optici, 630; on corpora striata, 631; on tuber annulare, 632, 746 *note*, 749; on vertigo, 628; on crura cerebri, 632 *note.*
Longet and Lafargue, on the cerebellum, 648.
Loos, on action of curare on heart, 298 *note.*
Loose connective tissue, 40.
Lortet, M., his hæmatochometer, 325; on animal heat, 501; on mal de montagne, 376.
Lösel, on optic chiasma, 623 *note.*
Lossen, on elimination of carbonic acid and ammonia by the breath, 374, 383.
Loss of blood, influence of, on composition of blood, 258.
Loss of weight in tissues in starvation, 112.
Lostorfer, on organisms in blood, 269 *note.*
Love, nature of, 873.
Lovén, on lymphatics of stomach, 145; on rhythmical movements in vessels, 307; on vaso-motor centre, 308, 309, 852 *note;* on giant cells of bone, 419; on sympathetic nerve, 848 *note.*
Löwenberg, on section of semicircular canals, 628.
Lower jaw, development of, 951.
Lower, relative capacity of cardiac cavities, 274.
Löwig, on glycogeny, 447.
Lowit, on milk, 974 *note.*
Lubbock, Sir John, on the Danish peat-mosses, 983.
Lucæ, on Eustachian tube, 771 *note.*
Luchsinger, on glycogeny, 449, 450, 455, 790 *note.*
Luchsinger and Kendall, on nervous mechanism of secretion of sweat, 491.
Luciani and Tamburini, on lesions of cerebrum, 675 *note.*
Ludwig, Prof., on absorption by lymphatics, 185; on lymphatics, 193; on sweat, 859; on sounds of heart, 284; on cardio-motor ganglia, 287; on effects of increased pressure on heart, 291; on innervation of heart, 293, 295 *note*, 848; on influence of position on pulse, 301; on vaso-motor centre, 308; his kymographion, 320; on pressure in arteries, 320; his Stromuhr, 324; rapidity of blood current in arteries, 324; on tension of carbonic acid in lungs, 380; on calorific value of sugar, 380; on kidney, 457 *note;* on trophic nerves, 854; on rapidity of circulation in capillaries, 329; on rapidity of flow of urine, 465; on movements of stomach, 858; on circulation in muscle, 802; on lymph, 200; on oxidation in blood, 343.
Luiscius, on milk of mare, 976.
Luminosity of living body, 519.
Lungs, exhalation by, 382; absorption by, 384; substances found in tissue of, 347; structure of, 344; contractility of bronchial tubes of, 347; elasticity of, 348; force required for their distension, 354; mechanism of their expansion, 349; capacity of, 366; changes in, from section of pneumogastrics, 365; development of, 933, 934.
Luschka, M., on nerves of pericardium, 272; on nerve-endings of nipple, 895 *note.*
Lusk, on glycogeny, 456 *note.*
Lussana, M. P., on origin of fibrin, 246 *note;* on reabsorption of bile, 446; on the cerebellum, 647, 650, 651 *note;* on nerves of taste, 624, 708 *note.*

Lutein, 74.
Luxus consumption of food, 413.
Luys, on spinal cord, 570 *note;* on cerebellum, 651 *note;* on cerebrum, 657 *note.*
Lyell, Sir Charles, on the antiquity of man, 981, 982 *note.*
Lymph corpuscles, origin of, 50; paths pursued by, 192; canalicular system, 193; paths, superficial and deep, 195, 196; characters and composition of, 199–202; quantity of, 200; microscopic characters of, 200; plasma, 202; serum, 202; ferment, 202; forces effecting the movement of, 206; pressure of, against the walls of the lymphatics, 206; influence of nervous system on amount of, 206; development of red corpuscles from, 252.
Lymphatics, 177; cells, 193; sinuses, 195; hearts, 204; origin of, 197; distribution of, in stomach, 145; in intestines, 178; in nervous centres, 188; in spleen, 210; in liver, 439; in gall bladder, 432 *note;* in kidneys, 461; in heart, 275; in lungs, 347; glandulæ of, 194, 199; absorption by, 192; contents of, 202 (see *Lymph*).

MACDONNELL, on glycogenic function of liver, 449, 450, 451, 455, 790 *note.*
MacGillavry, M., on biliary ducts, 437; on structure of liver, 438, 439.
Macgregor, Mr., on elimination of carbonic acid, 374.
Mach, M., on sense of time in the ear, 777 *note;* on kinetic theory of hearing, 774.
Mack, on hippuric acid, 477.
Mackenzie, Dr., on the laryngoscope, 832 *note.*
Maclachlan, Dr. D., on the diseases of advanced life, 1027 *note.*
Maclagan, on temperature of infants, 499.
Maclaurin, Dr. H. N., on independent irritability of muscle, 807 *note.*
Macnamara, Dr., on muscle, 785 *note.*
Macula lutea, 731.
M'William, Dr., on artificial lactation, 970.
Madden, Dr. W. H., on cutaneous absorption, 189; on pulmonary absorption, 384.
Maddox, on ending of gustatory nerves, 710 *note.*
Magendie, M., on act of vomiting, 124; on trophic nerves, 855; on alteration of blood in disease, 270; on blood, 270; on action of intercostals, 352; on albuminous urine, 462 *note;* on cutaneous respiration, 512; on roots of spinal nerves, 541; on removal of cerebrum, 625, 626; on cerebellum, 645, 646 *note,* 648; on effects of withdrawal of cerebro-spinal fluid, 666; on corpora striata, 631; on falsetto voice, 837; on section of fifth nerve, 585; on olfactory nerve, 620; on absorption, 183.
Maggiorani, on spleen, 211.
Magyar race, 998, 1002.
Maintenance of the organism, 428; during period of maturity, 1109.
Malacorps, on functions of cerebrum, 626.
Malassez, on globular richness of blood, 219, 225, 226; on blood of splenic vein, 264.
Malayo-Polynesian race, 1009.
Malcolm, Mr., on excretion of carbonic acid, 374.
Mal de montagne, 376.
Male, rudimentary uterus in, 1021; rudimental mammary gland in, 1047; lactation by, 969 *note,* 1048; influence of, on progeny, 986; on sex, 962; size and weight of, at birth, 962; subsequent increase of, 964; viability of, 963; puberty of, 952; his character as compared with female, 965; share of, in generation (see *Generation.*)
Malignant growths, 482.
——— pustule, cause of, 67.
Malleus, 951.
Malpighian bodies, of kidney, 513, 514; of spleen, 207.
Malting, influence of heat upon, 6 *note.*
Maltose, 84.
Maly, on cholepyrrhin, 442 *note,* 478; on pigments of bile and urine, 478.
Mammary gland, structure of, 966–968; functional activity of, 968; influence of mental states upon, 860; in male, 969; development of, 968; changes in, 968; functional activity of, in men, 969 *note,* 1048; periods of activity, 970; secretion of, 977 (see *Milk*).
Man, distinctive characters of, 15; hand of, 17, 18; foot of, 18, 19; cranium of, 20–23; vertebral column of, 23; lower extremities of, 18, 24; facial angle of, 23; myology of, 26; visceral apparatus of, 27; brain of, 27–30; subordination of senses to intelligence of, 28: peculiar adaptability of, 30; slow growth of, 30; mental endowments of, 31, 534; articulate speech of, 31 capacity for progress of, 31, 32; muscular current in, 522.
——— epochs of life of, 1012: antiquity of, 981; species of, 983; embryonic life, 1012; infancy, 1013; childhood, 1017 youth, 1020; adolescence, 1022; maturity, 1025; decline, 1026.
——— varieties of, 979, 983 (see *Colour, Hair, Languages, Pelvis, Races, Skull, Varieties,* and *Skeleton*).
Manassein, on action of reagents on blood-corpuscles, 230 *note;* on size of red corpuscles in fever, 380; on animal heat, 501.
Manchester, organic matter in air of, 393.
Mandelstamm, on optic commissure, 623; on perception of colour, 752.
Mandibular arch, 949.
Mandl, on glottis, 831; on falsetto voice, 837.
Manganja, action of poison of, on heart, 319.
Manometer, differential, 319; spring, 321.
Mansvelt, on elasticity of muscle, 795.

Mantegazza, on number of red corpuscles, 266; on coagulation of blood, 244, 246; on arrest of respiration, 361; on uræmia, 463 *note;* on spermatozoa, 872 *note.*
Mara, Mad., her compass of voice, 826 *note,* 904 *note.*
Maragliano, on dicrotic pulse, 314.
Marc, M., on suspended animation, 388.
Marcet, Dr., on composition of blood in disease, 268; on animal heat, 501; on composition of fæces, 172.
Marchand, M., on influence of diet on blood, 258 *note;* his analysis of urine, 468 *note;* on heart sounds, 284 *note,* 288 *note.*
Marchi, on ciliated epithelium, 781.
Marey, M., his cardiograph, 282; on character of cardiac contraction, 284, 287; his sphygmograph, 312, 313; on the dynamics of the circulation, 314, 315; on movements of respiration, 317, 350, 356; on torpedo, 521; on rapidity of transmission of impulses along motor nerves, 553; on muscle, 784 *note;* on phenomena of muscular contraction, 799, 800, 801 *note;* on locomotion, 814.
Märker, on elimination of carbonic acid, 373; on spontaneous ventilation, 392.
Markwald, on intestinal digestion, 171.
Marmé, on nervous mechanism of secretion of sweat, 491 *note.*
Marriage of relations, influence of, on progeny, 904.
Marrow, the seat of cell formation, 50; red, 218.
Marshall, Prof. Milnes, on development, 953, 956, 957.
Marshall, Mr., on development of veins, 929; on cerebral convolution, 658 *note;* on weight of brain, 664 *note,* 665.
Marsh, Sir H., on evolution of light, 519.
Martin, Alexis St., digestion in, 150.
Martin, H. N., on respiration regulating centre, 356; on respiration in frog, 362 *note;* on olfactory nerves, 716 *note.*
Martin-Magron, on action of poison on muscle, 801 *note.*
Martyn, Dr., on structure of muscular fibre, 785 *note.*
Martyn, Dr. P., on the functions of the thyroid body in regard to the voice, 829 *note.*
Masius, on bladder, 488; on stercobilin, 173, 477; on pigments of bile and urine, 477; on spinal cord, 601.
Masoin, on inhibition of heart's action, 290 *note,* 294 *note.*
Masquelin and Swaen, on development of placenta, 891.
Masson, on sensitiveness of retina, 759.
Mastication, act of, 117; nerves of, 118; centre for, 611.
Maté, 109.
Maternal impressions, 864, 906.
Mathieu and D'Urbain, MM., on pneumatology of blood, 258.
Matrix of cartilage, 45.
Matschersky, on formation of hippuric acid, 477 *note.*
Matteucci, Prof., on disturbance of electric equilibrium in organic processes, 521; on development of electricity by muscular contraction, 797; on electrical condition of nerves, 561 *note,* 563.
Maturity, characteristics of, 1025.
Mauchamp breed of sheep, 993 *note.*
Maudsley, Dr., on convolutions of brain, 659 *note.*
Mayer, Dr., on the correlation of force, 13; on spleen, 211; on vicarious secretion of urine, 432.
Mayer, Dr. S., on biliary ducts, 437 *note;* on glycogeny, 453.
Mayer, M., on action of oxygenated blood on muscle, 793 *note;* on vaso-motor centre, 309; on seat of oxydizing processes, 419; on rami communicantes, 847 *note.*
Mayhew, Mr. Henry, case quoted, 777 *note;* on nomadic races, 991 *note,* 1007 *note.*
Mayo, Dr. H., on action of intercostals, 352; on optic chiasma, 622; on guiding sensations, 639; on falsetto voice, 837; on muscle, 788; on death, 1033 *note.*
Mays, on structure of tendon, 41.
McKendrick, on functions of corpora quadrigemina, 618, 627; on electrical conditions of optic nerve, 756.
Meat, bad economy of exclusive diet of, 88; composition of, 97; effects of diet of, on balance of vital economy, 442; effects of diseased, 99.
Meatus venosus Arantii, 922.
Mechanical theory of fermentation, 65.
Mechanism of respiratory acts, 349.
Meckel, on cardiac ventricles, 274; trophic nerve of, 584; ganglion of, 587.
Meconium, nature of, 174, 445.
Mecznikow, ciliated cells in uriniferous tubules, 459.
Medulla oblongata, 536, 644; structure of, 573–582; substance of, 578; origin of various nerves from, 577–582; motor tract of, 583; sensory tract of, 583, 618; special endowments of, 679; effects of stimulation of, 127; influence of, on respiration, 359; homologies of, 536; course of fibres in, 574–577; reflex action of, 610; respiratory centre in, 610; centres in, 611; weight of, 664 (see *Spinal Cord*); relations of spinal cord to, 576; pyramidal column of, 577; grey tubercle of Rolando in, 577; columns of, 577–578; nuclei of, 577–582, 611; locus niger, 581, 619, 631; functions of strands, 612.
——— spinalis, 565 (see *Spinal Cord*).
Medullary folds or laminæ, 917; canal, 917.
——— substance of nerves, structure of, 525.
——— cells of bone, 50.
Medullated nerve fibres, 523–526.
Medullo-cells of bone, 50.
Meihuisen, on action of bromide of potassium on reflex excitability of cord, 605.

Meissner, Prof., on hippuric acid, 79, 477; on sympathetic ganglia in walls of intestine, 126; plexus of, 145, 179; on peptones, 163; on action of curare on vagus, 298 *note;* on presence of uric acid in blood, 480; on nerves of touch, 699 *note,* 704; corpuscles of, 699; on trophic nerves, 858.
Meissner and Shephard, on origin of hippuric acid, 477.
Melanin, 41.
Membrana granulosa, 956; development of, 940.
——— preformativa of teeth, 57.
——— reuniens superior, 945.
——— tympani, structure and uses of, 769.
Menopause, 879.
Mensonides, on absorption of solid particles, 185.
Menstrual fluid, 878.
Menstruation, influence of, on respiration, 370; period of, 877; persistence of, 878; influence of, on conception, 884; superstitions in connection with, 878 *note.*
Mering, Von, on pancreatic fermentation, 161; effects of foods upon glycogen formation, 449; on sugar, 84.
Merkel, V., on adrenals, 213; on muscle, 784 *note:* on spermatozoa, 871 *note;* on vision, 719 *note.*
Meroblastic ova, 912.
Mesencephalon, functions of, 702; development of, 919.
Mesenteric blood, special characters of, 263.
——— glandulæ, structure of, 199.
Mesmeric state, 686, 692, 864.
Mesoblast, 914; structures derived from, 915; cleavage of, 916.
Mesocephale, 632; effects of section of, 697; effects of electric current on, 697, 698.
Metals entering into composition of the body, 60.
Metamorphosis of matter, required in organic functions, 431; during development, 866.
Metapepton, 149.
Metastasis of secretion, 486.
Methæmoglobin, 235, 237.
Methyl glycocyanin, 77.
——— uramin, 77.
Metschnikoff, on inhibition of heart's action, 290 *note.*
Meyer, on effects of exclusive diets, 97 *note;* on gases contained in blood, 260, on centre of gravity of body, 813; on innervation of heart, 290 *note,* 292, 294, 295 *note;* on nerve stimuli, 548.
Meyerstein and Thiry, on loss of heat at commencement of muscular contraction, 793 *note,* 794.
Meynert, on spinal cord, 573; on medulla oblongata, 574; on cerebellum, 645 *note;* on structure of cerebrum, 659 *note,* 660; fasciculus of, 631; on weight of cerebrum, 664.
Mialhe, M., on osmosis, 185; on albuminuria, 263.
Michael, on voice, 838.
Michaelis, on nerve regeneration, 528 *note.*
Michel, on optic chiasma, 623 *note;* on Daltonism, 754 *note.*
Michelson, on rigor mortis, 810; on corpuscula tactûs, 699 *note.*
Michieli, on cerebrum, 673 *note.*
Micropyle, 886.
Micturition, influence of, upon excretion of urea, 474.
Midbrain, 954.
Middeldorf, on fatty degeneration, 201.
Miescher, on white corpuscles, 232; on vasomotor centre, 308.
Migration of white corpuscles, 236, 477.
Mihalkovics, on development of notochord, 944.
Milk, index of refraction for, 970; specific gravity of, 970; cream, 970; butter, 970; buttermilk, 970; souring of milk, 971; digestion of, 971; whey, 971; casein, 971, 973; colostrum, 972; milk globules, 971; fats of, 973; lactose or sugar of milk, 973; salts of, 974; beast milk, 974; green milk, 975; as a food, 976; value of, as food, 95; secretory apparatus of, 967; supply of, 1047; constituents of, 970–977; microscopical characters of, 971; variations in their proportions, 972, 974; influence of mental states on, 860; varieties of, in different animals, 976; relation of, to blood, 1055; re-absorption of, 978; vicarious secretion of, 978; quantity of, secreted, 978; passages of medicines, &c., into, 978; reaction of, 970; fat in, 897 *note;* secretion of, in man, 969 *note,* 977; sugar of, 84, 977.
Mill, Mr. James, on ideation, 681 *note.*
Millbank prison, scurvy at, 114.
Miller, Prof., on composition of air, 367.
Millon, on the metals in blood, 256.
Millon's reagent, 60.
Milne-Edwards, Prof. H., on irrigation of tissues, 205; on formation of fat, 413; on influence of season on mortality of children, 518.
Mimetic centre, 611.
Mincopie race of the Andaman Isles, 1010 *note.*
Mind, of man, its distinctive characteristics, 33, 593; its influence on organic functions, 930, 937; variation of, at different periods of life, 916, 968, 976.
Emotional activity of, 598, 752, 933.
Idio-dynamic activity of, 598.
Mitchell, Dr., on hereditary disease, 904 *note;* on vagus, 297 *note.*
Mitchell, Dr. Weir, on nerve lesions, 504 *note;* on action of cold on nervous centres, 682; on trophic nerves, 858; on cerebellum, 647.
Mitchell, James, case of, 717.
Mitivié, on influence of age on pulse, 301 *note.*
Mivart, Prof., on the genetic relation between man and apes, 26 *note.*

Mixed diet, economy of, 87 ; importance of, 88.
Modelling process, 467 ; means of promoting, 468.
Moens, on the velocity of pulse wave, 313.
Mohl, on protoplasm, 35.
Moisture of air, influence of, on respiration, 370.
Mojsisovics, on nerves of skin, 698.
Moldenhaver, on membrana tympani, 769.
Molecular base of chyle, 203.
——— death, 1029, 1031.
Moleschott, on composition of food, 97 ; on innervation of heart, 290 *note ;* on proportion of colourless corpuscles to red, 233 ; on size of pulmonary air-cells, 346 *note ;* on unstriped muscle, 783.
Mongolian race, in Europe, 998 ; in India, 1001–1003.
Monk, on effect of acids on heart, 287.
Monniki, on tension of eye, 720 *note.*
Monstrosities, by excess, 457 ; by arrest of development, 431, 1012, 1023, 1026, 1031
Montgomery, Dr., on muscle, 784 *note ;* on placental bruit, 893 ; on duration of pregnancy, 900 *note ;* on influence of mother on fœtus, 906 *note.*
Moore, Mr., on casein of human milk, 973 *note.*
Moore, Prof., on vocalization, 840.
Moos, M., on glycogeny, 452 ; on sense of taste, 708 *note.*
Morbid poisons, 282 (see *Poisons, Morbid*).
Moreau, M., on effects of division of intestinal nerves, 127 ; on hachisch, 691 *note ;* on determination of age of fœtus, 1014 *note.*
Morgagni, hydatids of, 942.
Morison, on osteophagous cells, 419.
Mortality, preventible, of England, 427 ; relative at different seasons, 518 ; at different ages, 1024.
Morton, Dr. S., on the antiquity of man, 981 *note.*
Mosler, on effects of extirpation of spleen, 218.
Mosso, rate of movement in capillaries, 329.
Mother, influence of mental states of, on fœtus, 989, 991 ; on mammary secretion, 939.
Motion, centres for, 675 *note.*
Motor centres, 632, 643.
——— nerves, laws of transmission through, 543 (see *Efferent Nerve-fibres*).
——— tract of medulla oblongata, 583, 618.
Mougeot, M., on absorption by skin, 194.
Moura, Dr., on deglutition, 118, 119.
Moutard-Martin, urine in relation to blood pressure, 465 *note.*
Movements of eye, 817, 818.
——— post-mortem, 809.
Moxon, Dr., on aphasia, 678.
Mucus, quantity of, in urine, 468.
Mucin, 72 ; in bile, 441.
Mule, characters of, 986 ; sterility of, 995.
Müller, C. W., on influence of pressure on respiration, 375.
Müller, Dr. H., on subjective phenomena of vision, 757.
Müller, J. W. M., on the structure of cells, 37 ; on the spleen, 207 ; on the thyroid body, 216 ; on spectrum analysis of blood, 239 ; on gases of blood, 255 ; on coagulation of blood, 246 ; on pressure of blood, 339 ; on respiration, 379 ; on action of nervous system on liver, 439.
Müller, Prof. Max, on the science of language, 997 *note.*
Müller, Prof., on size of capillaries, 327 ; on erectile tissue, 340 ; on respiration in hydrogen, 379 ; on respiration of oxygen, 385 ; on roots of spinal nerves, 541 ; on laws of nervous transmission, 542 ; on cerebellum, 648 ; on visual purple, 730 ; on the horopter, 740 ; on complementary colours, 752 ; on acoustic principles of hearing, 767, 772 *note ;* on movements of vocal cords, 826 ; on mechanism of voice, 832, 835, 836, 844 ; on micropyli, 886 ; on venous system of fishes, 928 *note.*
Müllerian duct, development of, 936, 940.
Müller's muscle, 723.
Multiplication of cells, 34–36 ; free cell, 34 ; endogenous, 35 ; by fission, 36 ; by gemmation, 36.
Munk, Dr., on ferments, 69 ; on rapidity of motor impulses, 553 ; on electrical phenomena in nerves, 555 ; on origin of urinary constituents, 479 *note ;* effect of nerves on bile secretion, 446 *note ;* on weight of brain, 664 *note ;* on optic nerve, 720.
Murphy, Prof., his cases of protracted gestation, 901 *note.*
Murri, on animal heat, 508 *note.*
Muscarin, 81 ; action of, on heart, 293.
Muscle albumin, 61.
——— plates, 945.
——— sugar, 85.
——— caskets, 785.
——— ferments, 789.
——— elements, 785.
——— rods, 787.
——— corpuscles, 284.
——— plasma, 789.
Muscles, capillaries of, 327 ; limited term of life of, 432, 865 ; degeneration of, 432, 897 ; hypertrophy of, 864 ; atrophy of, 865 ; electric current of, 748 ; of respiration, 352.
Muscular apparatus of organic life, 856 ; of animal life, 856.
——— movements, increase of contractile power of, after section of spinal cord, 687 ; post-mortem, 805, 809 ; voluntary and involuntary, 811 ; grouping of, 812 ; symmetry and harmony of, 813–817 ; energy and rapidity of, 820 ; absolute muscle force, 821 ; sources of muscular force, 823 ; rapidity of, 797, 826 ; precise adjustment of, 826 (see *Muscular Sense*).
——— sense, 650, 703, 778, 779 ; its participation in voluntary movements, 637, 639 ; its exaltation in somnambulism, 693.

Muscular tension, influence of spinal cord on, 616.
——— tone, 616.
——— tissue, Engelmann's theory of striated muscle, 785; Krause's theory, 785; Rouget's theory, 785 *note;* Schäfer's theory, 786; termination of nerves in, 787; extractives of, 789, 793; proportion of nerve fibres to muscles, 787; sensory nerves of, 788; hæmoglobin in cardia muscle, 789; reaction of, 790, 793; gases of, 790; specific heat of, 790; glycogen in, 790; effect of action of, 791; influence of apnœa upon, 793; amount of shortening of, 794; sound accompanying contraction of, 794; conductility of, 797; conditions of tetanized, 797; latent period of, 798; muscle curve, 798; exhaustion of, 800; neuro-muscular contraction of, 801; wave of muscular contraction, 802; circulation in muscle during contraction, 802; influence of heat on unstriated form of, 802; action of drugs on, 802; action of curare on, 803; effect of ether on, 804; inhibitory influence of nerves on contraction of, 804; on rhythmical movements of, 805 *note;* overloading of, 806; influence of nervous system on, 806; independent irritability of, 807; on flow of blood through, 807; on restoration of muscular irritability, 808; on post-mortem irritability of, 808; rigor mortis of, 809; myosin ferment, 810; effects of exhaustion on production of rigor mortis in, 810; heat rigor, 810; acid rigor, 810; reaction of, in rigor mortis, 810; absorption of gases by, 811; lifting weights by, 821; on relation of temperature to muscular action, 795 *note,* 822; influence of nitrogenous diet on, 824; of non-nitrogenous, 825; on theory of contraction, 825; disintegration of, 825; increase in contraction of, by means of electrical current, 825; influence of sympathetic on, 853; influence of, on pulse, 301; various forms of, 780, 781; structure of unstriated, 782; structure of striped, 783; distribution of motor nerves in, 783, 787; distribution of blood to striped form of, 787; lymphatics of, 787; chemical composition of, 788; chemical changes in, induced by exhaustion, 790; development of, 790; nutrition of, 791; limited duration of, 432, 791; elongated and contracted conditions of, 792; phenomena accompanying contraction of, 783, 791; elasticity of, 794; electrical relations of, 521, 553, 796; mechanism of muscular contraction, 798; idio-muscular contraction of, 801; peculiarity of that of heart, 274, 288, 800, 804; arrangement of that of the heart, 272; tetanus of, 801; various stimuli inducing contraction of, 793; examples of rhythmical movement of, 804; irritability of, 802; agents destroying irritability of, 802; effects of shock in destroying irritability of, 805; proofs of essential independence of irritability of, 805; necessity of due supply of arterial blood for maintenance of irritability of, 807; laws of contraction of, 561.
Muscularis mucosa, 145.
Musculus, on fermentation, 66; on starch, 84; on pancreatic fermentation, 161.
Musical tones, theory of, 836.
Musk, power of, 714.
Mutism, 680.
Mycoderma aceti, 66.
Mydriasis, 636.
Myelin, 72, 526.
Myelocytes, 568.
Myeloplastes, 218, 419.
Myenteric plexus, 124.
Myopia, 725.
Myopolar, 551.
Myopsin, 69, 161.
Myosin, 61, 530, 789, 825; ferment, 810.
Myrosin, 68.

NAIRNE, Dr., his case of softening of spinal cord, 602 *note.*
Naoumoff, on respiration of oxygen, 385.
Nasse, Prof., on movements of stomach, 123; on splanchnics, 128; on respiratory centres, 358; on quantity of bile, 166; on spleen, 220; on specific gravity of blood, 224; on influence of nerves on movement of lymph, 206; on fat in blood, 254; on sympathetic nerve in thorax, 928; on influence of food on secretion of liver, 445, 450; on movements of intestine, 848 *note.*
Nates, 589; effect of stimulating, 618.
Naunyn, on temperature in disease, 503 *note,* 505 *note.*
Nausea produced by pressure, 709.
Navy, diet scale of, 96.
Nawrocki, on kreatin and kreatinin, 777; on gases contained in blood, 257; on chemistry of contracted muscle, 793; on vaso-motor centre, 308; on pressure under which the urine is secreted, 545; on muscle, 789 *note;* on nervous mechanism of secretion of sweat, 491 *note.*
Neanderthal skull, 982.
Necræmia, death by, 1031.
Nedvetski, on organisms in blood, 267.
Negative variation in nerve, 557.
Negrier, on maturation of ova, 879.
Negrito race, 1009.
Negro, change of colour in, 985 *note.*
——— races, 1003; languages of, 1004; colour of, 987 *note;* hair of, 986; skull of, 987; modification of its form by civilization, 1070; pelvis of, 991; immunity from fever of, 994 *note;* geographical range and varieties of, 1003.
Neill, on villi of stomach, 143.
Nencki, on skatol, 90; on pancreatic digestion, 163; on digestion, 176; on excretion of urea, 474, 497 *note.*
Nephrozyme, 478.
Nepveu, on organisms in blood, 269.
Nerium oleander, action of, on heart, 319.

Nerve force, laws of transmission of, 603.
Nerves, of pericardium, 272; accelerator fibres, 290, 295; action of reagents on, 523, 524; structure of, 523, 524, 526; points of difference between the medullated and non-medullated forms, 524; nuclei of, 524; corpuscles, 524; elasticity of, 526; extensibility of, 526; cohesion of, 526; termination of, 526, 699; in muscle, 787; cells, 527, 528; sensory, 527; excito-motor, 527; motor, 527; secretory, 527; reaction of, 530, 550; avalanche effect, 551; Ritter-Valli's law, 551; electric current in, 555–556; negative variation in, 557; anelectrotonic, condition of, 558; katelectrotonic, condition of, 558; excitability of, 561–562: origin and course of spinal nerves, 569, 570; segmental, 595; of the special senses, 680; electrical phenomena in optic, 756; proportion of, to muscles, 788; sensory, of muscle, 788; influence of apnœa upon, 793; influence of, on muscle, 806; gelatinous fibres, 847.
Nervi erigentes, 310, 340, 609, 852.
Nervous impulse, path of, 538.
——— tissue, limited duration of, 433; atrophy of, 462; reparation of, 529, 855.
Nervous System, 523; influence of, on animal heat, 503, 515; on heart, 285; general arrangement of, 528; regeneration of nervous tissue, 528–529; chemistry of, 529; automatic character of, in invertebrata, 531, 532; distinguished in vertebrata by cerebrum and ministering to intelligence, 531, 534; comparative anatomy of, 530, 538; method of determining functions of, 547.
Cerebro-spinal system, 535; principal divisions of, 523, 535; cranio-spinal axis, 631; sensory ganglia, 688; cerebral hemispheres, 729: cerebellum, 716; general course of action of, 539; reflex operations of separate parts, 539; subordination of these to the will, 539; relations of, to sympathetic system, 540; influence of, on animal heat, 515, 516; on organic functions, 845, 849; visualisation, 758; psychology of, 531, 533; lymphatics of, 569; see *Cerebellum, Cerebrum, Cord, Spinal, Crura Cerebri, Crura Cerebelli, Cervix Cornu, Caput Cornu, Cerebral Centres, Cerebro-spinal System, Medulla Oblongata, Sensory Ganglia, Spinal Cord, Consciousness, Emotions, Excito-motor Actions, Ideo-motor Actions, Intellectual Faculties, Reflex Actions, Sensory-motor Actions, Volitional Actions.*
Sympathetic system, general structure of, 846; cerebro-spinal fibres in, 846; connection and distribution of principal trunks, 847–850; results of section and of irritation of sympathetic, 806, 850; fibres, dilating vessels, 848, 850, 852; action of, on apparatus of organic life, 849; their instrumentality in sensation in muscular contraction, 803, 849; on muscular elongation, 853; action of, on intestinal canal, 152, 848, 952; on heart, 295, 848; on blood-vessels, 847, 852; on uterus, 848; on eye, 85, 858; on iris, 812; proper fibres of, 846; splanchnics, action of, 851; influence of, on secretion generally, 858; of organic life, 540; sympathetic action on sexual secretions, 859; on secretions of skin, 859; on urine, 859; on mammary glands, 860; on secretion of saliva, 137, 848, 858; on secretion of gastric juice, 858; on lachrymal secretion, 858; on sweat, 491, 859; on nutrition, 854; on animal heat, 503, 515, 951; reflex actions of, 672; trophic nerves, 854.
Trunks, endowments of, 530; connection of, with central organs, 545; functions of, methods of determining, 546; afferent and efferent, 541, 527, 546; central, 527; use of plexuses of, 542; laws of transmission in, 603; modes of determining their functions, 544, 548; action of various stimuli on, 548–550, 564; rapidity of conduction of electrical stimulus by, 551–553; electrical phenomena in, 550, 553; electrotonic condition of, 556; electro-motor properties of, 555; capillaries of, 523.
Nessler, solution of, 383; on respiration, 413.
Neubauer, on myelin, 68; on urine, 469, 478, 483 *note*, 477; referred-to, 477 *note*, 482 *note*.
Neufeld, on action of antiaris on heart, 297 *note*.
Neuman, David, on theory of muscular contraction, 787 *note;* on post-mortem irritability of muscle, 808 *note*.
Neumann, on ciliated cells in digestive tract, 38 *note;* on glycogen, 85; on development of white corpuscles in the marrow of bones, 50, 218; on the teeth, 54; on chorda tympani, 624 *note;* on spermatozoa, 708 *note*, 871 *note*.
Neurilemma, 523, 526.
Neurin, 81.
Neuroglia, 568; synonyms for, 661, 730.
Neurology and Electrology, Report of the New York Society of, 675.
Neuro-muscular cells, 782.
——— contraction of muscle, 801.
Newport, Mr., on insects, 137; on blood corpuscles of insects, 279; on increase of carbonic acid excreted by exercise, 372; on nervous ganglia of articulata, referred-to, 572 *note;* on fertilizing power of spermatozoa, 869, 872 *note*, 885 *note*, 886; on embryonic development of batrachia, 909 *note*.
Nicol, Dr., on length of muscular fibres, 784.
Nicotin, action of, on heart, 293, 320; neuro-muscular contraction, 876.
Nieder, on animal heat, 504 *note*.
Niemetschek, on Daltonism, 755 *note*.
Night, elimination of carbonic acid and absorption of oxygen during, 372, 375.

Nîmes, prison of, mortality at, 114.
Nitric acid in urine, 484.
Nitrogen, its presence in blood, 260 ; respiration of, 359, 379 ; exhalation and absorption of, 369, 381 ; excretion of, 404, 528 ; amount of, in muscle, 790 ; uses of, 824 ; quantity required in food, 402.
Nitrous oxide, effects of respiration of, 359, 385.
Nobili, his law of muscular contraction, 561.
Noble, Mr., his cases of paralysis of fifth pair, 590.
Nodus cursorius, 631 *note*, 673 *note*.
Noel, on gases of bile, 440.
Noeud vital, 356.
Noll, on pressure of lymph in lymphatics, 206.
Non-medullated nerve fibres, 526 ; action of reagents on, 526 ; size of, 526.
Norris, Dr., on aggregation of red corpuscles, 230 ; on irritability of muscle, 805 *note* ; on emigration of white corpuscles, 331 ; on signs of death, 1033 *note* ; on blood corpuscles, 225 ; on colourless corpuscles, 234.
Norris, Mr., on Syro-Arabian race, 1006 ; on population of India, 1085 ; on Hottentot language, 1006 *note* ; on Australian language, 1011.
North, on muscular work, 402.
Nothnagel, M., on lesion of optic thalami, 630 ; of corpora striata, 630 ; on effects of lesion of cerebral convolutions, 673 ; on perception of temperature, 706.
Notochord, formation of, 917.
Nowak, on elimination of nitrogen, 382 ; on nutrition, 406 *note*.
Nuclein, 72 ; in liver, 438 ; in nerve, 530.
Nucleus, movements of, 35 ; of cells, 34.
Nuel, on inhibition of heart's action, 290 *note*.
Nunneley, on action of poisons on heart, 298 *note*.
Nüssbaumer, his case of excitation of optic centres by sound, 698.
Nüssbaum, on kidney, 461 ; on elimination of urea, 470 ; on heart, 296.
Nutrition, general nature of 280, 396 ; dependent on pabulum in blood, 396 ; complemental doctrine of, 281 ; sources of demand for, in increase, 397 ; in development, 397 ; in waste, 398 ; conditions of its performance, 401 ; interstitial and superficial, 419 ; varying activity of, 422 ; at different periods of life, 1102, 1110, 1113 ; abnormal degrees of, 457 ; peculiar phases of, in reparation of injuries, 463 ; abnormal forms of, 471 ; inflammation and its results, 471 ; tuberculosis, 481 ; malignant growths, 483 ; influence of nervous system on, 421, 846, 862, 854 ; electric disturbance in, 579.
Nysten, on excretion of carbonic acid, 374 ; on vicarious secretion of urine, 431 ; on irritability of muscle, 805.

OBERMEIER, on organisms in blood, 269 *note*.
Oblique muscles of eye, function of, 817.
Obolensky, on trophic fibres, 856.
Observation, active in infancy, 1016.
Observations, astronomical, mode of recording, 777.
Oceanic races, 1008.
Ocular spectra, 751.
Oculo-motorius, 588.
Odoriferous secretion of skin, influence of nervous system on, 859.
Odontoblasts, 56.
Odoroscopy, 715.
Odorous matter in blood, 1026.
Odour of blood, 254.
Odours, nature of, 714 ; varieties of, 715.
Œcoid, 227.
Oedmannson, on absorption by lymphatics, 185.
Oeffinger, on cells of villi, 182.
Oehl, M., on regeneration of nerves, 528 *note* ; on increase of temperature in nerves during action, 551.
Oellacher, on development of chick, 885 *note*, 910 *note*, 914.
Oertel, on pitch of notes, 835, 837.
Oertmann, on injection of saline solutions into frogs, 380 ; on thermometry, 498 *note*.
Œsophagus, movements of, in swallowing, 118, 119.
Oesterlen, on absorption of solid particles, 185.
Ogle, Dr. W., on action of belladonna on heart of rabbits, 298 *note* ; on temperature of the body, 500 ; on preferential use of right hand, 817 ; on glycogeny, 456.
Ogston, Dr., on bone, 52.
Oidtmann, on muscle, 790 *note* ; analysis of lymphatic glands, 196 *note*.
Olbers, on limits of distinct vision, 722 *note*.
Old age, characteristics of, 1027 ; diminished power of generating heat in, 499, 500, 507.
Oldham, Dr., on period of conception, 884 *note*.
Oleaginous constituents of food, 88, 93 ; digestion of, 161, 164 ; absorption of, by investing cells of Villi, 177 *note*.
Olfactive cells, 715, 716.
——— region, 716.
——— ganglia, 617.
——— nerve, 581, 620, 714 ; distribution of, 715 ; effects of stimulating, 717.
Olivary bodies, 578, 611 ; fasciculi, 574.
Ollivier, M., on heart, 297 *note* ; on albuminuria, 462 *note* ; on urine, 467 *note* ; on cerebellum, 654.
Omichmyl, oxide of, in urine, 469.
Omicholein, 478 *note*.
Omicholic acid, 478 *note*.
Omphalo-mesaraic vessels, 920, 929.
Onimus, on movements of leucocytes, 35 ; on action of electrical currents on nerves, 550 *note*, 554 *note* ; on electro-tonus, 563.
Ophthalmic branch of fifth pair, 587.
——— ganglion, 586, 621, 848.
Ophthalmometer, 722.
Opisthotic bone, 951.
Oppler, M., on origin of urinary constituents, 479 *note* ; on uræmia, 463 *note*.

Optic commissure, 622.
—— ganglia, 537, 618, 650.
—— lobes, comparative anatomy of, 618.
—— nerves, endowments of, 620, 720; distribution of, 728; deficient sensibility at entrance of, into globe of eye, 756; origin of, 725; decussation of, 622, 739; effects of lesions of, 627.
—— thalami, 581, 661; functions of, 630, 633, 644; weight of, 664, 673.
—— nerve, macula lutea, 731; fovea centralis, 732; number of fibres in, 732; electrical changes in, 756.
—— tract, 739 *note*.
Optogram, 731.
Orang-outan, comparison of, with man, 18–32.
Orbit, nerves of, 587.
Oré, M., on course of sensory fibres in spinal cord, 600; on ligature of hepatic centres, 443.
Organic functions, influence of nervous system on, 846.
Ornithuric acid, 79.
Orth, on organisms in blood, 269 *note*.
Orton, Mr., on physiology of breeding, 902 *note*.
Oser, on action of nicotin on heart, 298 *note*; on uterine contraction, 895 *note*.
Osmosis of constituents of food, 185.
Osseous tissue, 46; structure of, 47; development of, 51.
Ossicula auditûs, 770.
Ossification, intra-cartilaginous, 51; intra-membranous, 52; completion of, a mark of adolescence, 1022.
Osteoblasts, 51.
Osteoclasts, 419.
Osteogenic fibres, 53.
Ostroumow, on nervous mechanism of secretion of sweat, 491 *note*.
Otic ganglion, 587, 770, 848.
Otoconia, 773.
Otoliths, 764, 773.
Ott and Woodfield, on nervous mechanism of secretion of sweat, 491.
Oulmont, on action of hyoscyamin and daturin on heart, 298 *note*.
Outrepoint, Dr., his case of early viability, 899 *note*.
Ovalbumin (see *Egg albumin*).
Oval skull, 989.
Oval-skulled type of man, 997.
Ovarium, structure of, 874; development of, 874, 938; evolution of ovisacs within, 875; discharge of ova from, 877, 884.
Overbeck, on albuminuria, 462 *note*.
Overcrowding a predisposing cause of zymotic disease, 391.
Oviduct, length of time of ovum in, 886 *note*, 913; changes of ovum during passage through, 913.
Ovigerms, 942.
Ovisac, 876, 881.
Ovum, structure of primordial, 875; size of, 876; evolution of, 874, 939; maturation and discharge of, 876; fertilization of, 880; period of escape, 884; first changes in, 908; structure of, 910; subsequent changes in (see *Development of Embryo*); changes in, previous to fertilization, 885; provisions for nutrition of, 886; of bird, 909; of mammal, 911; development of membrana granulosa, 940; liquor folliculi, 940; discus proligerus, 940; zona pellucida, 940.
Owen, Prof., on the divisions of the mammalia, founded on the brain, 15; on anthropoid apes, 23; on typical vertebra, 947; on Mauchamp breed of sheep, 993; on the Mincopie race of the Andaman isles, 1010 *note*; on origin of species, 981.
Owsjannikow, on vaso-motor centre, 308.
Oxalic acid, action on heart, 298 *note*; in urine, 468, 469, 483.
Oxaluric acid, 468.
Oxidation of tissues, 380.
Oxindol, 77.
Oxygen, amount of, in blood, 259; sources of demand for, 342; quantity of, required, 404, 411; excretion of, 404; respiration in, 376, 385; effects of, on corpuscles, 380 effects of deficiency of, 386.
Oxyhæmoglobin, 235.

PACINIAN bodies, 700.
Packard, on development, 866 *note*.
Pagenstecher, on intracranial pressure, 339.
Paget, Dr., on morbid rhythmical movements, 650 *note*.
Paget, Sir James, on retarded coagulation of blood, 251; on fibrin, 264; on contractile movements of heart, 275; on effects of mechanical irritation on smaller arteries, 307 *note*; on formative power of individual parts, 401, 419; on fatty degeneration of lymph, 420; on exuviation of dead parts, 421; on reparative power, 401; on incipient changes in atrophy, 420; on healing processes, 426; on regeneration of nerve tissue, 529; his case of deficient commissures, 677; on influence of nervous system on nutrition, 854.
Palladino, on nerves ending in salivary glands, 849.
Palmitic acid in urine, 468.
Pancreas, charging of, in digestion, 148; structure of, 158; nerves of, 160; development of, 159, 933.
Pancreatic ferments, 69, 70.
———— fluid, composition of, 159; quantity of, 160, 403; influence of nervous system on, 160; action of, on starch, 161; on fat, 161; on albumen, 163.
———— peptones, 163.
Pander, germinal membrane of, 913; on development of vessels, 920 *note*.
Panizza, on uses of plexuses, 542.
Panspermists, 865.
Pansphygmograph of Brondgeest, 350.
Panum, Dr., on the Faroe islanders, 105; on action of heat on heart, 288 *note*; on respiration, 369, 374, 375.

Papillæ, tactile, 698; gustative, 709.
Papillon, on bone salts, 415; on odours, 715 *note*.
Papuan race, 1010.
Par vagum, origin, 579, 591; distribution, 592 (see *Pneumogastric Nerve*).
Paraglobulin, identical with fibrinoplastin, 63; method of obtaining, 244.
Paralactic acid, 789, 802.
Paralyzed limbs, temperature of, 504; condition of muscle in, 792.
Parapeptone, formation of, from albumen, 149.
Paraphanic acid in urine, 468.
Paraplasm, 35.
Paraplegia, peculiar cases of, 596.
Parelectronomic condition of nerves, 555.
Parents, influence of, on progeny, 902 (see GENERATION, *Influence of Parents*).
Parent-Duchâtelet, M., on inhalation of sulphuretted hydrogen, 384.
Parisot, on cutaneous absorption, 190.
Parker, on development of shoulder girdle, 947.
——— Mr. Langston, on mercurial inhalation, 387 *note*.
——— Mr. W. K., on development, 910 *note*; on different modes of ossification, 947; on the development of the temporal bone in birds, 980.
Parkes, Dr., on supra-renal capsules, 213; on excretion of nitrogen, 93; on nutrition, 404, 411; on influence of liq. potassæ on solids of urine, 487; on quantity of urine, 464; on composition of urine, 469; on elimination of urea, 471, 473; on elimination of phosphates by urine, 482; of sulphates, 482; on muscle force, 824, 825; on influence of sex in relation to excretion of urea, 411; on diet, 102; on elimination of nitrogen, 404.
Parostosis, 947.
Parotid gland, 138, 139; secretion of, 139; nervous supply of, 588.
Paroophoron, 942.
Parovarium, 942.
Parrot and Robin, on urine, 469.
Parry, Capt., on gluttony, 104; on resistance to cold, 506.
Parthenogenesis, 914.
Parturition, act of, 895, 897; regular period and causes of, 896, 897; premature, 899; retarded, 900; centre for, 610, 897.
Paschutin, on ptyalin, 136; on intestinal digestion, 170; on pressure of lymph in lymphatics, 205; on smell, 716 *note*.
Passion, influence of, on secretion of milk, 860.
Pastem, on fermentation, 66.
Pasteur, M., on formation of fat, 414.
Patellar reflex, 603.
Paton, Dr., on sounds of heart, 284 *note*.
Paulus, Dr., on tactile sensibility, 702; on function of cerebrum, 626 *note*.
Paupers, dietary of, 102.
Pavy, Dr., on self-digestion of stomach, 151; on amyloid substance in blood, 250; on glycogeny, 448–456.
Pawlinoff, on origin of urea, 480; on urea, 474 *note*.
Payen, M., on economy of admixture of animal and vegetable food, 96.
Peas, composition of, 97.
Peculiarities of circulation in different parts, 338.
Peddie, Dr., on mammary secretion, referred-to, 969 *note*.
Pelagian-Negro race, 1009.
Pelikan and Dybkowsky, on action of Tanghinia on heart, 297 *note*.
Pelvis, form of, in different races, 987, 991.
Pennock, on influence of age on pulse, 301 *note*.
Pepsin, 65, 69, 147, 789; effect of, on coagulation, 251.
Pepsinogen, 70.
Peptic digestion, 148.
Peptones, formation of, from albuminous compounds, 148; in urine, 469.
Perceptive centres of cerebrum, 679.
Percy, Baron, on siege of Landau, 906.
Percy, Dr., on absorption of alcohol, 183.
Peremeschko, M., on structure of spleen, 207, 211; on nerves of thymus gland, 214, 217.
Peremeschkow, on capillaries of ligamentum nuchæ, 328.
Perforating fibres of bone, 48, 53.
Pericardium, 196; structure of, 272; nerves of, 272.
Perilymph, 773.
Perimetry, 724.
Perimedullary lamellæ of bone, 48.
Perineurium, 523.
Periosteum, structure of, 47.
Peripheric lamellæ of bone, 48.
Peripolar molecules in nerves, 555.
Peristaltic movement of intestines, 126; effects of venous blood on, 126; effects of irritation of various parts of nervous system on, 127; influence of mental states on, 130, 853.
Peritoneal epithelium, 936.
Peritoneum, 196.
Perivascular lymphatics in liver, 439; in nervous system, 568.
Perrin, on elimination of carbonic acid, 371.
Persian race, 998.
Persistence of sensory impressions—tactile, 703; gustative, 714; olfactive, 718; visual, 748.
Personal equation of astronomical observers, 777.
Perspective, visual, 744.
Perspiration, 489–496 (see *Sudoriparous Excretion*).
Petersen, on nutrition, 406; on muscle, 790.
Pétrequin, M., on function of cerebellum, 655; on falsetto voice, 838.
Petrowsky, on composition of brain, 529; on glycogen in muscle, 790 *note*.
Pettenkofer, M., test for bile, 82; on mois-

ture of air, 368; his respiration apparatus, 395; on nutrition, 402, 404; on formation of fat, 414; bile test, spectrum of, 443
Pettenkofer and Voit, on elimination of carbonic acid, 375; on air in relation to clothing, 392; on respiration in air charged with carbonic acid, 393; on cause of sleep, 681.
Pettigrew, J. Bell, on the mechanism of circulation, 272 *note;* on arrangement of heart muscle, 272–274; on relative capacity of cardiac ventricles, 274; on locomotion, 814 *note;* on heart, 277 *note;* on the muscular fibres of stomach, 121.
Peyerian glandulæ, structure and relations of, 180, 198.
Peyrani, on renal circulation, 466 *note.*
Pfaundler, on sound, 760 *note.*
Pfeiffer, on pulmonary circulation, 338.
Pflüger, on gases of blood, 259, 260; on influence of vagus on heart, 290 *note,* 292 *note;* on cause of dyspnœa, 358; on respiration, 359, 362, 379, 385; on oxidation of tissues, 380; on structure of liver cells, 438; on nerves of liver, 439; on electrical phenomena in nerves, 446, 551, 554; on electrotonus, 557; on anelectrotonus and cathelectrotonus, 558–564; classification of reflex actions, 605; on spinal cord, 607; on cause of sleep, 681; on sympathetic ganglia, 849; on gases of bile, 440; on ovaries, 940.
Phantasmagoria, 746, 776.
Phenol, 89.
Phenylic acid in urine, 468, 478.
Philip, Dr. Wilson, on independent action of heart, 285 *note;* on animal heat, 501.
Philippeaux, on the spleen, 211; on adrenals, 212.
Philippeaux and Vulpian, on union of sensory with motor nerves, 543.
Phlebin, 235.
Phonation, theory of, 837.
Phosphates, alkaline, in blood, 255; in urine, 468, 482; earthy, in urine, 482.
Phosphènes, investigation of, 757.
Phosphorescence of living body, 519.
Phosphorus, elimination of, by breath, 383, 520; by urine, 520; by semen, 520 *note.*
Phosphuretted hydrogen gas, effects of inhalation of, 384.
Photophobia, 621.
Photosphygmograph, 316.
Phrenic nerves, function of, 363.
Phrenological doctrine of cerebellum, 651.
Phthisis, influence of, on pulse, 302.
Physical basis of life, 32.
——— theory of fermentation, 65.
Physiological time, meaning of term, 553, 778.
Picard, on globular richness of splenic venous blood, 219; on proportion of urea in renal, arterial, and venous blood, 221, 264, 479.
Pick, on central lesions, 677; on structure of spinal cord, 570 *note.*
Pickford, on effects of temperature on heart, 288 *note.*
Picot, on migration of white corpuscles, 331; on uræmia, 463 *note.*
Piercepied, on iris, 736.
Pigment cells, 39.
Pincus, on effect of section of nerves on stomach, 123.
Pinel-Grandchamp, M., on function of cerebellum, 650.
Pineal gland, 663.
Piotrowski, M., on composition of muscle, 789.
Pircher, on urine, 468 *note.*
Piria's test for tyrosin, 76.
Piso-Borme, on structure of lungs, 346.
Pitch of sounds, appreciation of, 774.
—— of voice, regulation of, 826, 830.
Pitres, on latent stimulation of cerebrum, 673.
Pituitary body, 217.
Place, M., on duration of latent excitation in muscle, 798 *note,* 799 *note.*
Placenta, comparative anatomy of, 889 *note,* 825, 842; formation of fœtal portion of, 898; of maternal portion, 887; bile acids in, 444; presence of glycogen in, 450; structure of, 891; vascular supply of, 892; bruit of, 893.
Placental murmur, 893.
Planer, on gases contained in urine, 484.
Plasma of blood, 225, 242.
Plasmin, 242–244.
Plastides, 33, 65.
Plateau, M., on muscular power of insects, 822 *note.*
Plattner, on quantity of bile, 166.
Platyrrhine apes, comparison of thumb of, with that of man, 17.
Playfair, on diet in training, 104.
——— Dr. L., on absolute amount of work performed by body, 417; on relation of food to work, 825 *note;* on composition of milk, 974.
Plethysmograph, 337.
Pleura, structure of, 196.
Pleuroperitoneal cavity, 916.
Pleurosthotonos, 630 *note.*
Plexus myentericus, 126.
Plexuses, 846; uses of, 542, 592.
Ploss, on the cause of variation of sex, 961.
Plosz, on peptones, 148; on ferment of blood, 255; on albuminous compounds of liver, 438.
Pneumatology of the blood, 258.
Pneumogastric nerve, origin of, 678; general distribution and endowments of, 545, 591, 595; its instrumentality in deglutition, 120; in hunger and satiety, 110 *note;* its influence on secretion of gastric fluid, and on movements of stomach, 123; on movements of intestine, 127; on movements of heart, 227, 285, 290, 293; its action as excitor of respiration, 359–365, 547; its influence on larynx, 361, 830, 832; effects of section of, 360–365; regeneration of, 529; number of fibres in, 591; ganglion of root, 591; of trunk, 592; depressor nerve, 592; trophic fibres of, 854; cardio-inhibitory fibres of, 291.

Pneumogastric, interference, action of, 295.
Pneumogastrics, influence of, on the secretion of glycogen, 453.
Pneumograph, 350.
Poincaré, on thyroid gland, 216.
Points, focal, of the eye, 721.
——— nodal, of the eye, 720
——— principal, of the eye, 720.
Pointer and setter, inter-breeding of, 903.
Poisseuille, M., on urea in blood, 264; his experiments on influence of viscidity on capillary flow, 270; on the rate of circulation, 299; on extinction of pulse wave, 317; on lateral pressure of blood within arteries, 319; on glycogeny, 448.
Pokrowski, M., on action of carbonic oxide on heart, 298 *note*.
Polaillon, on action of inea on heart, 298 *note*.
Politzer, on ossicula auditûs, 771 *note*.
Pollack, on quantity of urine, 465; on urine of infants, 467, 470.
Polli, Dr., on coagulation of blood, 249, 251.
Polynesian races, 1009.
Polyuria, 465–466.
Poncet, on left-handedness, 817 *note*.
Ponfick, on spleen, 220.
Pons varolii, 574; structure of, 582, 662; effects of stimulation of, 127; effects of section of, 632, 644.
Poore, Dr., on increase of muscular power by electrical currents, 825.
Poorten, on Eustachian tube, 771 *note*.
Portal, on cardiac ventricles, 274; on closure of pupil, 736.
——— circulation, 271, 338.
——— vein, blood of, 262; comparison of, with blood of hepatic vein, 262; its distribution in liver, 434.
Portio dura, origin of, 580; functions of, 589.
Positive accommodation of the eye, 722.
Posterior columns of spinal cord, 596.
Posture, influence of, on pulse, 301.
Potash, effect of, on urine, 487.
Potassium bromide, action on heart, 298.
Potatoes, composition of, 97.
Pouchet, on relation of nerves to pigment cells, 39; on ovulation, 882 *note*.
——— and Tourneux, 457 *note*.
Power, on albumins, 69.
——— D'Arcy, and Brunton, on effects of purely albuminous diet, 462 *note*; on secretion of urine, 466; on ferments eliminated by urine, 468.
——— Henry, case of paralysis of the fifth, 858.
Pravaz, on action of compressed air on pulse, 302.
Pregnancy, influence of, on respiration, 370; signs of, 893, 895 (see *Gestation*).
Prehension of food, movements of, 116.
Presbyopia, 727.
Pressor fibres, 599.
Pressure of blood in arteries, 319; in veins, 334; increased during inspiration, 334; influence of, on secretion of urine, 465; endocardial, 276; in heart, 276.
Prestwich, Mr. J., on the flint implements of Moulin-Quignon, 981.
Preussen, on the cause of variation of sex, 961.
Prevertebral ganglia, 846.
Prévost, on action of veratrin, 802; on fifth nerve, 849, 928, 586; on odoroscopy, 715.
——— and Dumas, MM., on fertilizing power of spermatozoa, 872 *note*.
——— and Waller, on deglutition, 120.
Preyer, M., on action of hydrocyanic acid on heart, 298 *note*; on hæmoglobin, 237, 241; on blood-crystals, 239; on Daltonism, 754 *note*.
Pribram, on vaso-motor centre, 309.
Prichard, Dr., on varieties of man, 984 *note*; on typical forms of skull, 987, 988; on changes in domesticated animals, 993 *note*; on psychical conformity of human races, 995; on Aryan race, 998; on somatic death, 1029 *note*.
Prideaux, on functions of cerebellum, 651 *note*.
Priestley, on lymphatic hearts, 204; on stimulation of vagus, 293 *note*; on ova previous to fertilization, 885 *note*; on segmentation of ova, 911.
Primary vertebræ, 945.
Primitive aorta, 945.
——— dental groove, 55.
——— streak and groove, 908, 915; band 524; nerve fibrillæ, 524.
Prisons, diet scale of, 103.
Pritchard, Dr. U., on cochlea, 763, 764.
Prochaska, on reflex acts, 606.
Prognathous skull, 987.
Projection of objects, visual appreciation of, 744; system of Meynert, 661.
Pronuclei, male, 885; female, 885.
Prootic bone, 951.
Propionic acid, 89.
Prosencephalon, development of, 919.
Prostate gland, function of, 869.
Protagon, 72.
Proteids, 59.
Proteolytic ferments, 69.
Protein of Hofmann, 62; of Soyka, 63.
Protista, 33.
Protoplasm, 32, 908; movement of, 33; composition of, 33.
Protovertebræ, 918; formation of, 945.
Protracted gestation, 900.
Prout, Dr., on acid of gastric juice, 146; on secondary digestion, 192; on excretion, 430; on quantity of urine, 465; on its specific gravity, 467.
Prussak, on migration of white corpuscles, 332.
Pseudofibrin, 62.
Pseudoscope, 747.
Pseudo-stomata of serous membrane, 198.
Psycho-physical law, Fechner's, 778–780.
Ptosis, cause of, 588.
Ptyalin, 789.
Puberty, the characteristic of youth, 1021;

in female, 877 ; in male, 872; diseases of, 1022, 1024.
Puerperal fever, predisposing causes of, 287.
Pufahl, on perimetry, 725 *note*.
Puky Akos, on Brünner's glands, 168.
Pulmonary artery, blood pressure in, 321.
Pulse, arterial, 311 ; varieties of, 336; mode of propagation of, 315; dicrotic, 314; rapidity of propagation of, 316 ; dichrotous, 313; circumstances affecting, 300, 301.
Pupil, action of, 734, 735 ; influence of drugs on, 736 ; relation of, to third pair, 723, 735; to sympathetic, 735.
Purkinje, Prof., on retina, 751; optical experiment of, 757 ; on colours, 751 *note*.
Purves, on emigration of white corpuscles, 332.
Pus, formation and characters of, 467, 475, 477–480 ; influence of, on coagulation of blood, 248 ; in urine, 469.
Pustule, malignant, cause of, 62.
Putrescent food, injurious consequences of, 105; water, injurious effects of contaminated, 105.
Putzeys, on vaso-motor centre, 308 ; on spontaneous generation, 865 *note*.
Pye-Smith, on preferential use of right hand, 817.
Pyin, 72.
Pyramidal skull, 988.
Pyramids of medulla oblongata, 575.
Pyrenæmata, 228, 251.
Python, temperature of, during incubation, 11 *note*.

QUADRUMANA, comparison of, with man, 15–32.
Quagga, transmission of marks of, 905.
Quain and Sharpey, on nerve-tissue, 528 *note;* on cerebral convolutions, 658 *note*.
Quantity of air traversing lungs, 368.
Quekett, on elastic tissue in fæces, 172.
Quetelet, M., on rate of respiration at different ages, 355 ; on influence of seasons on mortality, 518 ; on length and weight of new-born infants, 962–965.
Quickening, act of, 895.
Quincke, on digestion, 170; on pulmonary circulation, 338 ; on animal heat, 503 *note*.
Quinine, action of, on heart, 275 *note*.
Quinoidin, animal, 81.

RABUTEAU, on gastric juice, 146 ; on uræmia, 463 *note*.
Rabbits, time required to asphyxiate, 388.
Races, visual peculiarities of, 759 ; origination of new, 992, 993.
—— of mankind, 997 ; Alforous, 1010 ; American, 1007 ; Arian or Indo-European, 998 ; Berber, 1001 ; Bushman, 1006 ; Caucasian, 998 ; Celtic, 999 ; Esquimaux, 1007 ; Hindostanic, 1003 ; Hottentot, 1006 ; Kaffre, 1005 ; Mongolian, 1003 ; Malayo-Polynesian, 1009 ; Mincopie, 1010 *note;* Negro, 1003; Oceanic, 1007; Pelagian-Negro, 1009 ; Seriform, 1002; Syro-Arabian, 1000 ; weight of brain in various, 664 *note*.
Raciborski, M., on periodical discharge of ova, 878, 879.
Radcliffe, Dr. C. B., on the electrical phenomena presented by nerve and muscle, 564 *note;* on muscular irritability, 808 ; on muscular contraction, 792.
Radziejewsky, on tyrosin, 75 ; on formation of fat, 413.
Rahlmann, on perception of colour by retina, 755 *note*.
Rainey, Mr. G., on structure of lungs, 344 *note*.
Rami communicantes, 296.
Range of vision, extent of, 759.
Ranke, Prof. Von, on work done by muscle, 824 ; on muscular force of heart, 285, 337 ; on muscular tissue of the heart, 274 ; on distribution of blood, 337 ; on elimination of carbonic acid in the fasting state, 378, 406 ; on proportion of constituents of body to each other, 402 ; his experiments on nutrition, 408; on amount of heat produced in the body, 513; on excretion of urea, 471 ; uric acid, 475 ; on excretion of salts, 483; on reaction of nerve tissue, 530, 549, 556 ; on chemical changes in muscle during contraction, 793 ; on relative conductivity of dead and living muscle for electricity, 797 ; on absorptive power of dead and living muscle for oxygen, 811; on water of nerve, 550 *note* ; on electrical condition of nerve, 563.
Ransom, Dr., on rotation of yolk, 780 ; on fertilization, 885 *note*, 886.
Ransome, on mechanism of respiration, 353 ; on expired air, 383.
Ranvier, on connective tissues, 39, 42 ; on relation of cartilage to polarised light, 45 *note;* on bone, 49, 52 ; on lymph corpuscles, 201 ; on capillaries of muscle, 328 ; on villi, 181 ; on structures derived from epiblast, 915 ; on differences between white and red muscles, 801 ; on effects of division of nerves on flow of lymph, 333 ; on structure of nerve fibres, 523, 524, 526 ; on nerve regeneration, 529 *note ;* nodes of, 523 ; on ciliated epithelium, 782; on muscle, 784 *note*, 798, 801.
Ranvier and Cornil, on structure of capillaries 327 *note*.
Rapidity of movement of blood, 323 ; transmission of impulses through motor nerves, 552; through sensory, 777, 778 ; of muscular movements, 820, 825.
Rarefied air, respiration of, 376.
Rate of movement of blood, 323.
Rathke, Dr., on development, 945, 909 *note;* on development of venous system, 928.
Rattle-snake, poison of, secretion after death, 1029 *note*.
Rattray, on vital capacity, 367.
Ratzel, on striated muscle, 784 *note*.

Rauber, on Pacinian bodies, 700.
Ravitsch, on influence of nerves on stomach, 155.
Rawitz, Dr., on components of fæces, 172 *note*.
Rayer, M., on albuminous urine, 462 *note*.
Reciprocation of sonorous vibrations, 836; by membrana tympani, 769.
Recklinghausen, v., on lymphatic system, 192, 194 *note;* on lymphatic glands, 195.
Recording stethometer, Sanderson's, 353.
Recurrent sensibility of spinal nerve roots, 541.
Red corpuscles, 225 (see *Blood*).
—— marrow, 218.
—— nucleus, 631.
Redfern, Dr., on atrophy of cartilage, 425.
Redtenbacher, on contractile power of muscle, 823.
Reeds, vibrating, laws of, 833.
Rees, Dr. G. O., on red corpuscles of blood, 228 *note;* on uræmia, 463 *note;* on composition of milk, 976.
Reflex actions, general nature of, 602; laws of, 603, 605; circumstances augmenting activity of, 610; of spinal cord, 602-607 (see *Excito-motor actions*); of sensory ganglia, 603, 635 (see *Sensori-motor actions*); course of, 604; co-ordinating centre for, 611; classifications of, 604, 605; greater in young animals, 605; influence of drugs on, 605; inhibition of, 606; effect of habit on, 615.
——— activity of respiratory centre, 358.
——— time, 606.
Refraction, laws of, 718.
Regimen, effects of, on blood, 258 (see *Diet, Food*).
Regnault and Reiset, MM., on absorption of oxygen, 374; on absorption and exhalation of nitrogen, 381.
Regulating centre for respiration, 356.
Reich, on perimetry, 724 *note*.
Reichert, on biliary ducts, 437; on structure of ear, 764 *note;* on ovum, 940; on the development of the guinea-pig, 910 *note;* on decidua reflexa, 888; on placenta, 891.
Reid, Dr. John, on sense of hunger, 110; on nerves of deglutition, 120; on movements of stomach, 123; on restoration of digestion after section of vagi, 155; on re-excitement of heart's action by relief of distension, 281; on function of vagus in respiration, 360; on laryngeal nerves, 361; on results of section of vagi 365; on asphyxia, 391; his case of hypertrophy of a limb, 423 *note;* on atrophy, 426, 857; on structure of medulla oblongata, 574; on spinal cord, 573 *note;* on functions of glosso-pharyngeal, 546, 590; on the effects of exercise on the nutrition of muscle, 792; on structure and connections of placenta, 891; on Eustachian valve, 930.
Reil, on nerves of internal senses, 680; Island of, 658; effects of stimulating, 672.
Reinhard, on cutaneous respiration, 377.
Reiset, M., on respiration, 381.
Reissner, membrane of, 765.
Relations, near, tendency of their marriage to produce imperfect progeny, 904.
Relief of surfaces, visual appreciation of, 740–743; conversion of, 747.
Remak, Dr., on spleen, 207; on cardio-motor ganglia, 285 *note*, 286; on restorative currents of electricity, 825; on sympathetic nerve, 846 *note;* on the development of the vertebrata, 910 *note;* fibres of, 526; on epiblast, 915.
Renal artery, 434.
——— circulation, 338.
——— compared with portal circulation, 459, 460.
——— vein, blood of, 264.
Renaut, on Brünner's glands, 168.
Rennet ferment, 971; varieties of, 973.
Renz and Wolff, on appreciation of intensity of sound, 777.
Renzi, on effects of lesion of corpora quadrigemina, 627; on cerebellum, 651 *note;* on thalami optici, 629.
Reparation of injuries, 426; completeness of, in lower animals, 427; limitations of, in higher, 426; most energetic and complete in earliest periods of life, 427; by adhesion, 427; by suppurative granulation, 428; influence of nervous system on, 850, 855.
Report of Committee of Medico-Chirurgical Society on hypodermic injection, 191.
Reproduction of protoplasm, 33; of limbs in fœtus, 427; of lower jaw, 427; of epithelium, 427; instinct of, 872.
Reserve sacs of teeth, 57.
Residual air, 366.
Resistance, sense of, 617, 702.
Resonance of sounds, 766.
Respiration, general nature of the function, 341; sources of demand for, 341–343; apparatus of, 344 (see *Lungs*); mechanism of acts of, 349; muscles of, 352; regulating centre, 356; of hydrogen, 379; of nitrogen, 379; of oxygen, 385.
Movements of, 350; rate and extent of, 379; force exerted in, 355; maintenance of, by nervous system, centre for, 610; muscles engaged in, 352; excitor nerves of, 352, 359–362, 547, 593; motor nerves of, 352; effects of section of vagi on, 360; modifications of, 363; effects of compression and rarefaction of air on, 375; influence of, on heart, 281.
Effects of, on air, 365; amount of air consumed, 368; changes in its proportions of oxygen and carbonic acid, 369; quantity of carbonic acid imparted to, 369–375; changes in proportion of nitrogen, 381; watery vapour imparted to, 382; absorption from, 384.
Effects of, on blood, 258–262; on blood-pressure, 322.
Consequences of suspension of, 387.
Effects of deficiency of, shown in predisposition to disease, 394; excess of mortality

attributable to, 395; apparatus of Pettenkofer for experiments on, 395.
Respiratory muscles, 352.
Respiratory murmur, 354.
Restiform bodies, 582, 575, 612.
Restorative currents, 825.
Rete mucosum, 37.
Retia mirabilia of lymphatics, 193.
Retina, structure of, 728–730; most sensitive point of, 732; least sensitive point of, 731, 755; persistence of impressions on, 748, irradiation of impressions on, 752, 755; spectra produced by pressure on, 757; circulation in, rendered visible, 758; circulation in, during sleep, 682; sensibility of, for stimuli, 734; zones in, for colours, 751; complementary colours from fatigue of, 751; functions of, 753.
Retzius, Dr., on fat in urine after parturition, 897 *note;* on ethnology in connection with the form of the skull, 997 *note;* on variations in position of cerebellum, 652 *note;* on structure of nerve fibres, 523.
Reverdin, on treatment of ulcers, 427.
Reverie, 686.
Reversion, 903.
Reynosa, on diabetes, 454.
Rhizopods, endowments of, 3.
Rhodopsin, 730.
Rhythmical movements of heart, 279 (see *Heart*); of vessels, 311; of diaphragm, 350; of cells, 780.
Ribot, M., on the measure of sensations, 778 *note.*
Ribs, development of, 946.
Richardson, Dr. B. W., on muscular irritability, 805 *note;* on elimination of ammonia, 383; on cold as a cause of sleep, 682.
——— Dr. J. G., on red corpuscles of blood, 226 *note.*
——— Sir J., on endurance of cold, 506 *note.*
Richet, on gastric juice, 146; secretion of urine in regard to blood pressure, 465 *note.*
Rickards, on temperature in relation to food, 502.
Ridard, M., on influence of emotions on nutrition, 862, 864.
Riegel, Dr., on rhythmical movements of vessels, 307; on respiratory movements, 350, 353; on heat dyspnœa, 507.
Riesel, on excretion of salts, 482 *note.*
Riess, on organisms in blood, 269 *note.*
Right-handedness, theories to account for, 817.
Rigor mortis, 793, 810; effects of previous exhaustion on, 810.
Rindfleisch, on lungs, 345; on cerebrum, 759 *note;* on development of blood corpuscles, 924.
Ringer, Sydney, on animal heat, 500, 502.
Risler, M., on the absorption of humours, 7.
Ritchie, Dr., on evolution of ova, 876 *note,* 879.
Ritter, on action of blood-corpuscles in respiration, 380; on alteration of secretion from changes in blood, 380; on number of corpuscles in lymph, 202; on pigments of blood and urine, 442 *note;* on jaundice, 445; on urine, 481; his law of muscular contractions, 551, 561; tetanus of, 626; on structure of retina, 729; on liver ferment, 451; on olfactory nerve, 717.
Ritthauser, on cholesterin, 88; on nutrition, 406 *note.*
Roberts, Dr. W., on influence of various reagents on blood-corpuscles, 227; on specific gravity of urine, 467; on acidity of urine, 484; on digestion of milk, 971, 973 *note.*
Roberts, Mr., his apparatus for reading cards in rapid motion, 749 *note.*
Robertson, Dr. Argyll, on Calabar bean, 727 *note.*
Robertson, Mr., on menstruation, 877 *note.*
Robin, M., on myeloplaxes, 50, 419; on lymphatics and capillaries of the brain, 188, 665 *note;* on helicine arteries, 340 *note;* on urine, 469; on neuroglia, 568; on irritability of muscle, 808 *note;* on male ovules, 871; on decidua, 897; formation of cartilage in embryo, 946.
Robinson, Mr., on strength of bone, 50; on absorption, 205; on albuminous urine, 462 *note.*
Rods and cones, functions of, 753.
Roger, M., on temperature of infants, 499, 505.
Rogow, M., on action of Calabar bean, 727 *note.*
Röhrig, on perspiration, 492 *note;* on cutaneous respiration, 377; on animal heat, 508; effect of blood supply upon secretion of bile, 443; on effect of bile acids on heart, 287; on effect of section of splanchnics and spinal cord upon bile flow, 446.
Rokitansky, Prof., on cerebrum, 661.
Rolando, M., on cerebellum, 646 *note;* substantia gelatinosa of, 565, 567; grey tubercle of, 577; fissure of, 558.
Rolleston and Greenwell, on British barrows, 982 *note,* 987 *note.*
Rollett, on blood, 228; on blood-crystals, 239.
Romberg, Dr., on nerves of taste, 590 *note.*
Rommeläre on uræmia, 463.
Romiti, on ovaries, 874 *note.*
Ronchi, on cutaneous respiration, 377.
Rood, Dr. O. N., on rapidity of perception, 752.
Rosapelli, blood pressure in vena portæ, 435.
Roscoe, Dr., on composition of the air of London, 393.
Rosellini, on antiquity of man, 981 *note.*
Rosenbach, on automatism of respiration, 357.
Rosenkranz, on re-absorption of bile, 446 *note.*
Rosenmüller, organ of, 942.
Rosenstein, on heart's impulse, 280; on uræmia, 463 *note,* 480 *note.*
Rosenthal, on cardiac ganglia, 287; on influence of vagi on lungs, 348, 360; on cause of apnœa, 358; on effects of hydrogen sulphide on heart, 298 *note;* on inhibitory influence of superior laryngeal nerves on

respiratory acts, 364; on medulla oblongata, 574 *note*; on retention of irritability by muscle after death, 808 *note;* on absolute muscle force, 822; on animal heat, 508 *note;* on number of fibres in nerves, 589; on reflex action, 606 *note*.
Rossbach, on action of poisons on heart, 299 *note;* on rhythmical movements, 781 *note*.
Rostan, M., on starvation, 113.
Rotifera, asplanchnic character of males of, 9 *note*.
Rouget, M., on zo-amylin, 449, 450; on helicine arteries, 340 *note;* on ganglia on phrenics, 363; on corpuscula tactûs, 699 *note;* on muscle, 785 *note*.
Roussin, on hippuric acid, 477.
Roux, on chorda tympani, 634.
Röver, on vaso-motor centre, 308 *note*.
Rüdinger, M., on structure of ear, 763, 764 *note*.
Ruge, on gases of large intestine, 175; on the urine of infants, 467.
Rugenberg, M., on influence of vagus on lungs, 348.
Ruhle, on vomiting, 125.
Rümmell, on excretion of urea, 470 *note*.
Running, 815.
Rutherford, Prof., on biliary secretion, 166, 446; on actions of heart, 282 *note;* on influence of vagus on the heart, 290, 291, 294, 295 *note;* on vaso-motor centre, 309; on electrotonus, 560; schema of circulation, 275 *note;* on cardiograph, 282 *note*.

SABADILLIN, action of, on heart, 298 *note*.
Sabatier, on action of intercostals, 352; on respiratory murmur, 354; on relative capacity of cardiac ventricles, 274.
Saccharine constituents of food, 93; digestion of, 161.
Saccharomyces cerevisiæ, 65, 66.
Sacculi of ear, 763.
Sachs, M., on cells of villi, 182; on structure of nerves, 524 *note;* on muscle, 784 *note*, 788.
Sadler, Mr., on pressure of blood in veins, 335; on proportion of sexes, 961.
Saint Louis bridge, respiratory experiments during building of, 375.
Saliva, composition of (*Appendix*); influence of nervous system on, 429, 611, 848; quantity of, secreted daily, 135, 403; influence of kind of food upon quantity of, 136; ferment in, 69.
Salivary glands, 132, 429.
Salkowsky, on phenol, 90; on hypoxanthin, 78; on glycogeny, 450; on source of urea, 479 *note;* on sweat centre, 611.
Salomon, on hypoxanthin, 78; on glycogeny, 449, 450, 455; on salts of urine, 483.
Salter, Dr. Hyde, on cause of respiratory murmur, 354; on mode of termination of muscular fibre, 783 *note*.
Salts, sodium chloride, advantage of, in food, 91; neutral, influence of, on change of colour of blood, 241; in retarding coagulation of blood, 251.
—— of blood, normal proportion of, 255; variations of, in disease, 269.
—— of urine, 481; of saliva (*Appendix*).
Salzer, on number of fibres in optic nerve, 733.
Samkowry, on action of heat on muscle, 802.
Samuel, on trophic nerves, 854.
Samuelson, on spontaneous generation, 865 *note*.
Sanders, Dr., on structure of spleen, 207.
——— Ezn, on innervation of intestine, 128; on posterior roots of spinal nerves, 598 *note*.
——— on effects of respiring dry air, 393.
Sanderson, Burdon, Prof., on phenomena of circulation, 224, 326; his cardiograph, 282, 512; on Traube's curves, 323; on means of exhibiting capillary circulation, 326 *note;* on extent of respiratory movements, 353; on action of vagi on respiration, 360; on asphyxia, 389; on cutaneous respiration, 512; on electrical excitation of cerebrum, 672; on spontaneous generation, 865 *note;* on coagulation of blood, 244 *note;* on organisms in blood, 269; on putrefactive processes, 428; on temperature in disease, 505; on corpora striata, 631.
Sanguification, process of, 192; of absorbent system, 196; of ductless glands, 218.
Sanguinarin, action of, on heart, 298 *note*.
Sanskritic languages, 999, 1003.
Sanson, on glycogeny, 448.
Sappey, M., on accessory venæ portarum, 444.
Sarcode, 32.
Sarcolactic acid, 86, 789.
Sarcolemma, 784.
Sarcous elements, 785.
Sarkin, 78, 469; in nerve, 530.
Sarkosin, 77, 477.
Sarokow, on nutrition, 412.
Satiety, sense of, 101.
Saunders, Mr. E., on dentition, 1020.
Saunderson, Prof., case of, 706.
Savart, M., on production of musical tones, 760, 836.
Saviotti, on pigment cells, 39; on rhythmical movements of vessels, 307.
Savory, Mr. W. S., on effects of non-azotized diet, 93; on advantage of plexiform arrangement of nerves, 542 *note;* on development of muscular fibre, 790, 791; on effects of poisoning the fœtus on mother, 893 *note;* on influence of non-nitrogenous diet on muscular contraction, 825.
Sawicki, on acids of urine, 482.
Scanzoni, on uterine contractions, 895 *note;* on development, 910 *note*.
Scapula, development of, 947.
Scarpe's tumour, 773.
Schäfer, on bone, 48, 49; on development of red corpuscles, 252; on muscle, 785 *note*, 786 on termination of nerves, 526 *note*.
Schafhäutl, on appreciation of sound, 779.

Schapringer, on tensor tympani, 769 *note.*
Scharling, Prof., on excretion of carbonic acid from lungs, 369, 371, 373; from skin, 377; on amount of carbon excreted by skin, 551; on urine, 469.
Scheffer, on effects of deprivation of water, 112.
Scheiner's experiment, 726, 749.
Scheinesson, on animal heat, 516.
Schelske, M., on action of heat on heart, 288 *note;* on rapidity of transmission of impulses through motor nerves, 553; on perception of colour by retina, 855 *note.*
Schenk, on respiration, 383; on nutrition, 406 *note;* on liver, 438 *note;* on spectrum of Pettenköfer's bile test, 442; on development of pancreas, 933 *note.*
Scheremetjewsky, on oxidation in blood, 343, 380; on diabetes, 455.
Scherer, on composition of gelatin, 71; on inosit, 85; on xanthin in urine, 478 *note.*
Schieferdecker, on nerve lesions, 855 *note.*
Schiff, Prof., on trypsin, 70; on ablation of spleen, 220; on movements of stomach, 123; on nerve centres governing movements of stomach, 123; on effects of section of vagus nerve on vomiting, 123; on innervation of intestine, 127; on saliva, 137, 138; on "charging" of pancreas, 148; on digestive action of pancreatic juice, 162; on digestive action of bile, 162; on innervation of heart, 276, 290 *note,* 295, 296, 297; influence of heat on heart, 290; on respiratory nerve-centres, 358; on respiratory nerves, 593 *note;* on arrest of respiration, 361; on dilatator fibres, 310; on section of vagus, 365; on structure of liver, 438 *note;* on re-absorption of bile, 446; on glycogeny, 451, 454; on liver ferment, 451; on albuminuria, 462 *note;* on influence of medulla on kidneys, 467; on liver, 452; on influence of the nervous system on development of heat, 503, 516 *note;* on regeneration of nerve, 529; on spinal cord, 598 *note;* on sympathetic, 850, 856; on the intestinal fluid, 170; on effects of ligature of coronary arteries on heart, 275; on rhythmical contraction of veins, 335; on effect of blood supply upon secretion of bile, 443; on chemistry of nerves, 529; on effects of various stimuli on motor nerves, 549, 550; on course of sensory fibres in spinal cord, 602; on æsthesodic substance, 600; on kinesodic substance, 598; on lesion of thalami optici, 630; on corpora striata, 630; on crura cerebri, 631; on cerebellum, 646 *note,* 648; on nerves of taste, 708 *note;* on muscular contraction, 801; on rhythmical movements, 805 *note;* on the sympathetic, 852; on analgesia, 608; on cerebrum, 666 *note,* 673 *note.*
Schiffer, on heat developed during muscular contraction, 793 *note.*
Schizomycetes, 66.
Schleich, on excitability of nerve, 549; on effect of temperature on elimination, 476.
Schlemmer, on Brunner's glands, 168.
Schlesinger, on uterine contractions, 895 *note.*
Schmidt, A., on fibrin, 244; on quantity of gastric juice, 146; on coagulation of blood, 244, 246; on salts of blood, 255; on elimination of carbonic acid, 380; on cellulose 447.
Schmidt, Dr. H. D., on development of blood-corpuscles, 252; on liver, 439 *note.*
Schmidt-Mulheim, on absorption, 184.
Schmidt, Oscar, on Tellina, 980, *note.*
Schmiedeberg, on hippuric acid, 79; on action of poisons on heart, 293 *note,* 298 *note;* on innervation of heart, 296; on origin of urea, 479, 483.
Schmulewitsch, M., on relation between muscle force and temperature, 795 *note,* 802 *note,* 822.
Schneider, Dr., his case of electric disturbance, 522; on striated muscle, 784 *note.*
Schneiderian membrane, 715; nervous supply of, 587.
Schnurman, on mean excursion of eye, 725.
Schöbl, on corpuscula tactûs, 699 *note.*
Schöpffer, on glycogeny, 450.
Schottin, on solids of sweat, 490 *note.*
Schreger, on cutaneous absorption, 191.
Schreiber, influence of nervous system on temperature, 504 *note.*
Schremetjewsky, on calorific value of sugar, 380.
Schröder, on source of urea, 479 *note.*
Schrodt, on asparaginic acid, 176; on source of urea, 479 *note.*
Schroeder van der Kolk, Prof., on coagulation of blood after destruction of central nervous system, 249.
Schroff, C. V., influence of nervous system on temperature, 504 *note.*
Schtschepotjew, action of quinine upon the heart, 275 *note.*
Schuh, on deglutition, 119.
Schukowsky, on milk, 974.
Schultz, Alex., on development of urinary organs, 934 *note.*
Schultze, Prof. M., on cells of villi, 183; on the retina, 753; on structure of nerve fibrils, 524, 528; on neuroglia, 568, 730; on the olfactory nerves, 716; on visual purple, 730 *note;* on the structure of the cochlea, 763; on muscular tissue, 784 *note;* test for albumin, 60; on spontaneous ventilation, 392.
——— R. B., on superfœtation, 902 *note.*
Schulz, Cecil, on glycogeny, 454; on action of oxygen on fats, 413; on trophic nerves, 858 *note.*
Schulze, Dr. F. E., on structure of lungs, 344; on elimination of carbonic acid, 373.
Schultzen, on excretion of urea, 474, 479 *note.*
Schunck, on colouring matter of urine, 478.
Schüster, on animal heat, 502, 508 *note.*
Schützenberger, on nutrition, 402.
Schwalbe, on unstriated muscular tissue, 782 *note;* on striated muscular tissue, 784 *note;*

on origin of nerves from cells, 847; on substantia gelatinosa, 567 *note;* on structure of medulla, 523 *note;* on taste buds, 711; on vision, 719 *note;* on milk, 972 *note.*
Schwann, on development of muscle, 791; on nodus cursorius, 631 *note;* on structure of nerves, 524; sheath of, 523, 524; white substance of, 524.
Schwartz, on milk, 972.
Schwarz, on apnœa, 358.
Schweigger-Seidel, on lymphatics, 185 *note;* on nerves of pericardium, 276; on ganglia of heart, 286 *note;* on muscle of heart, 274, 783 *note;* on structure of spleen, 207; on spermatozoa, 870 *note,* 871.
Scott, on phonautograph, 770 *note.*
Scoutetten, on the electricity of the blood, 521.
Scurvy, causes of, 99, 100 *note;* at Millbank, 114.
Sczelkow, on gases of blood, 262; on muscle, 787 *note,* 824.
Season, influence of, on pulse, 302.
Secondarily-automatic actions, 119–636.
Secretion, its relation to excretion, 428; vicarious relation between that of skin and kidneys, 494; influence of nervous system on, 846, 863; continuance of, after death, 1029 *note;* metastasis of, 432; (see *Bile, Gastric Juice, Milk, Pancreatic Fluid, Saliva, Urine,* &c.)
Sedgewick, A., on development of urinary organs, 934 *note,* 935.
Sée, M., on fibrin, 224.
Seebeck, on appreciation of minute differences in pitch of sounds, 777.
——— and Wartmann, on Daltonism, 754 *note.*
Seed, condition of, in dormant state, 2 *note.*
Seegen, on elimination of nitrogen, 381; on nutrition, 402 *note,* 406 *note,* 407; on glycogeny, 449.
Segmental nerves, 595.
Segmentation of ovum, 911, 913; of germinal vesicle, 884; cavity, 913.
Sehpurpur, 730.
Self-control (see *Volition*).
Semicircular canals, functions of, 773; effects of section of, 628.
Seminal fluid, characters of, 868; centre for emission of, 609.
Semitic race, 1000.
Semper, on development of urinary organs, 934 *note.*
Senac, on relative size of cardiac ventricles, 273; on heart's impulse, 279.
Senator, on glycogeny, 456 *note;* on regulating mechanism, 508; on effects of starvation on heat, 510; on amount of heat produced by body, 513, 514; on urinary pigment, 478.
Seng, Von, 458 *note.*
Sensations, general, 618, 624, 650, 694, 695, 697; special, 614, 620, 695, 704; localization of, 675; influence of light on, 696 *note;* rapidity of, 778; measurement of, 778; dependence of, on capillary circulation, 695; various kinds of, 696; guiding, 637; their seat in sensory ganglia, 434, 543, 613, 614, 635, 696; discrimination of, 543; radiation of, 543.
Sensibility, muscular, 703; tactile, relative, of different parts of skin, 700, 701 (see *Touch*).
Sensori-motor actions, 582; their correspondence with the instinctive of lower animals, 538; their independence of the cerebrum, 538, 635, 677, 680; their establishment by habit, 636; force, its dependence on heat, 10.
Sensorium, its special seat in the sensory ganglia, 625, 680; condition of, during dreaming, 682.
Sensory ganglia, general structure and relations of, 536, 617; their nerves, 572, 618, 697; their relative predominance in lower animals, 615, 618, 625; functions of, 625, 633; the probable seat of sensation for external impressions, 634, 644, 680 (see *Sensation*); also for cerebral changes, 580, 636–638; reflex functions of, 603, 635 (see *Sensori-motor Actions*); their participation in voluntary actions, 638, 641; relation to cerebro-spinal system, 540; their relative weight, 664.
——— nerves, laws of transmission through, 527, 543; nerves of special sense, 545, 599 (see *Afferent Nerve Fibres,* 582, 618).
——— tract of spinal cord, 597, 599.
Septal discs, 785.
Seriform race, 1002.
Serin, 244.
Sernoff, on structure of ovaries, 874 *note;* on development of urinary organ, 934 *note.*
Serous membranes, 196.
Serre, Dr., on phosphènes, 757.
Serres, M., on comparative anatomy of cerebellum, 645 *note;* on its pathology, 654; on functions of corpora quadrigemina, 618 *note.*
Sertoli, on gases of blood, 260; on corpuscula tactùs, 699 *note;* on taste organ, 711 *note.*
Serum, 242; proportion of, to crassamentum, 249.
——— albumin, composition of, 59.
——— casein, 63.
Setschenow, on colour of blood, 224; on inhibition of heart's action, 290 *note;* on blood in asphyxia, 390 *note;* on inhibition of reflex action, 606.
Setter and pointer, inter-breeding of, 903.
Seventh pair of nerves, deep origin of, 580.
Severé, Dr., on influence of gastric juice on alcoholic fermentation, 154.
Sexes, proportional number of, 961; differences in general development of, 962; in viability, 963; in composition of blood, 256; in pulse, 301; in respiration, 370; in physical character, 965; causes of difference of, 961.

Sexual organs, homologies of, 941–943.
——— sensation, probable seat of, 651, 656, 859; instinct of frog, 603 *note*.
Sharpey, Prof., on structure of bone, 48, 49; on spectrum analysis of blood, 239; on action of poison of manganja on heart, 297; on structure of muscular fibre, 785 *note*.
Sheep, new breeds of, 993 *note*.
Shephard, on hippuric acid, 79.
Sheppard and Meissner, on hippuric acid, 477.
Shettle, Dr., on electricity of the blood, 521.
Shock, cause of, 295; effect of, on heart, 295.
Shoulder girdle, development of, 947.
Sibson, Dr., on actions of heart, 277 *note*, 283; on sounds of heart, 287; on mechanism of respiration, 350 *note*.
Sieveking, Dr., on channels of sensation, 704 *note*.
Siewert, on nutrition, 406 *note*.
Sighing, act of, 363.
Sight, relation of, to corpora quadrigemina, 627.
Sikorski, on lymphatics of lungs, 347.
Silbermann, on calorific equivalents of carbon and hydrogen, 513.
Silkworm plague, cause of, 67.
Silvester, Dr. H. R., his mode of artificial respiration for the asphyxiated, 390.
Simon, Dr., on analysis of urine, 468 *note*; on specific gravity of urine, 467, 468; on variations in milk, 974; on milk of different animals, 976; on nature of meconium, 445.
——— Mr., coagulation of blood in the vessels, 247; on thymus gland, 214; on renal venous blood. 264.
Simpson, Dr., on pathology of cerebellum, 654 *note*.
——— Prof., on regeneration of limbs, 427; on hermaphrodism, 944 *note*.
Sinéty, De, on early appearance of milk, 968 *note*.
Single vision, conditions of, 739.
Sinitzin, on lesion of the fifth nerve, 857 *note*.
Sinkalin, 81.
Sinus rhomboidalis, 573, 954; terminalis, 921; venosus, 928.
Sion, Dr., his case of fat in the blood, 268.
Sitz, on temperature of infants, 500.
Six-fingered families, 993.
Sixth pair of nerves, 588; deep origin of, 580.
Size, visual appreciation of, 744.
Skatol, 90.
Skeleton, percentage weight of, 402; development of, 994; in different races, 987.
Skey, Mr., on training, 105; on muscular fibre, 784.
Skin, weight of, 402; structure of, 489; colour of, its variation in man, 984; absorption by, 188; respiration by, 376, 489, 495; transpiration from, 489, 494; nerves of, 698.
Skull, development of, 948; forms of, in different races, 987; prognathous, 987; pyramidal, 988; oval, 989; influence of habit on, 990; elliptical, 989; dolichocephalous, 987; brachycephalous, 987.
Sleep, definition of, 681; theory of cause of, 681, 684; circulation in the brain during, 681; dreaming during, 682; periodicity of, 683; how it differs from coma, 682; predisposing influences to, 684; means of inducing, 684; access of, 685; intermediate states between sleeping and waking, 685; influence of expectation and habit in inducing, 686, 687, 689; influence of impressions on the mind of the sleeper, 686; amount of, required by man, 688; cases of absence and deficiency of, 689; undue protraction of, 690.
Sloan, Dr., his case of abstinence, 116.
Smee, Mr. A. H., on gases of blood, 261; on artificial production of fibrin, 261.
Smell, sense of, 714; centre for, 675; nerves of, 714; their distribution, 715–717; conditions of, 716; uses of, 717; improvement of, 717; modification of, by habit, 717; duration of impressions on, 718; its participation in taste, 707, 713; exaltation of, in somnambulism, 693; development of, 960.
Smith, Dr. Andrew, on Bushmen, 1006.
——— Dr. Angus, on the air of Manchester, 393.
——— Dr. Edward, on disintegration of muscle, 93; on relation of carbonic acid exposed to muscular effort, 13; on healthy dietary, 102, 103; on circumstances affecting the rapidity of the pulse, 301, 302; on quantity of air respired per diem, 367; on amount of carbonic acid eliminated per diem, 369; on circumstances affecting the quantity of carbonic acid eliminated, 371, 824; on elimination of carbonic acid by lungs and skin, 377; on vapour exhaled by lungs, 382; on effects of season on flow of urine, 470; on quantity of urea, 470 *note*; on influence of tea and coffee on urine, 487; on quantity of urine, 465; on daily variations in quantity of urine, 470.
——— Dr. F. G., on temperature of stomach during digestion, 154.
——— Dr. Southwood, on cutaneous absorption, 189; on cutaneous transpiration, 493.
——— Mr. R. A., on pulmonary exhalation, 383.
——— Mr. Richard, on metallic tractors, 863 *note*.
——— Noble, and Klein, on structure of nerve fibres, 523 *note*.
Snake, temperature of, during incubation, 12 *note*; secretion of poison by, after death, 1029 *note*.
Sneezing, act of, 364, 830; centre for, 611; reflex, 622, 717.
Snellen, on influence of protection after section of the fifth, 585; on effects of section of the sympathetic upon reparative processes, 850, 857.

Snoring, nature of, 364.
Snow, on respiration of impure air, 393.
Sobbing, act of, 363.
Soborow, on excretion of calcium salts, 482 *note.*
Socoloff, on suppression of cutaneous respiration, 495, 512; on quantity of sulphur in taurin, 440.
Sodium chloride, uses of, 91.
Sodium taurocholate, 443.
Sodium glycocholate, 443.
Solar plexus of sympathetic, 846.
Solger, on heat evolved during contraction of muscle, 793 *note.*
Solidity, perception of, 742.
Solly, Mr. S., on optic chiasma, 622 *note.*
Soltmann, on cerebrum, 673.
Soluble ferments, 67.
Solyet, M., on dilator nerves, 310.
——— and Lafforet, on gases of blood, 259.
Somatic death, 1030.
Somatopleure, formation of, 916, 945.
Sommer, M., on cause of sleep, 681.
Somnambulism, 535, 681; relations of, to sleep and reverie, 692; suspension of volitional control in, 693; mesmeric, 693; phenomena of, 694.
Sorby, Mr., on spectrum analysis of the blood, 240.
Sounds, appreciation of, 760, 766; timbre of vowel sounds, 761; various modes of producing, 766; accompanying muscular contraction, 794, 826; of heart, 283; propagation of, 759; means of determining direction of, 776; distance of, 776; pitch of, 774; nature of musical, 760, 833; appreciation of, 769; sense of, 779; colours, 761.
Southey, Dr. Reg., on vessels of kidneys, 459 *note.*
Soxlet, on casein, 971 *note.*
Space, sense of, 702.
Spallanzani, on respiration in hydrogen, 378; on fertilizing power of spermatozoa, 872 *note.*
Spartein, action of, on heart, 298 *note.*
Species, origin of, 979–981.
Specific identity or diversity of human races, question of, 983.
Speck, on fat in blood, 268; on respiration, 372.
Spectrum analysis of the blood, 239; colours of, 753; of bile, 442; of sun, 749.
Speech, 839; participation of central organs in, 678; centre for, 611; rapidity of, 826; articulate, a distinguishing feature of man, 31; impediment in, 839; treatment of impediment in, 844.
Spencer, Earl, his cases of protracted gestation, 898, 900.
——— Herbert, 8 *note;* on the evolution of light, 519; on relation of development to reproduction, 874; on heredity, 904 *note.*
Sperm cell, influence of, 866.
Spermatoblasts, 871.
Spermatozoa, nature and evolution of, 866, 870, 871, ; importance of, in fecundation, 870, 871, 880, 885, 886; presence in urine, 469.
Spheno-palatine ganglion, 587, 849.
Spherical aberration, 719.
Sphincters, action of, 131, 616.
Sphygmographic tracing of the cardiac movements, 282; of arterial pulse, 313.
Sphygmographs, construction of, 313.
Spiegelberg, on uræmia, 463; on reflex action of uterus, 895 *note.*
Spigelius, on action of intercostals, 352.
Spinal-accessory nerve, deep origin of, 578; distribution and functions of, 592, 832; number of fibres in, 593.
Spinal cord, structure of, 566; external conformation of, 565; vesicular substance of, 566; fibrous strands of, 569; connection of, with nerve-roots, 569; lymphatics of, 569; course of fibres in, 570; grey substance of, 600, 609; weight of, 664; sympathetic columns of, 565; substantia gelatinosa, 565, fig., 567; filum terminale, structure of, 565 *note;* fissures of, 565; columns, 566, 568, 571, 575, 596; of Goll, 566, 571; of Burdach, 566, 571, 597; substantia spongiosa, 567; cells of Gerlach, 567; of Deiters, 567; commissures of, 567; central canal of, 568; dorsal nuclei of Stilling, 568; centres of Krause, 568 *note;* pathological evidence of, structure of 571; course of fibres in, 569–573; cephalic fibres of, 572; evidence from comparative anatomy, 572; fasciculus of Rolando, 575; relations of, to medulla, 576.
Functions of, 596; as a conductor of sensory impressions and of motor impulses, 596; as an independent centre, 602; its proper reflex actions, 541, 602, 607; co-ordinating centre for, 611; their relation to the organic functions, 612; their protective character, 612; their subservience to locomotion, 614; its influence on muscular tension, 616; development of, 953; relation to cerebro-spinal system, 540; functions of posterior columns, 597; antero-lateral columns, 598; vaso-motor fibres of, 598; substance of kinesodic, 598 *note;* effects of partial section of, 597–600, 609; decussation of fibres of, 599; centres in, 609; trophic fibres of, 847, 855; rami communicantes, 847.
Spinal nerves, 584; double function of their roots, 541, 546; their connection with the spinal cord, 584; relations of, with sympathetic, 540; recurrent sensibility of, 541.
Spiro, on sarcolactic acid, 85.
Splanchnic nerves, 294, 308, 848, 951, 1128.
Splanchnopleure, formation of, 916, 945.
Spleen, structure of, 207; lymphatics of, 210; nerves of, 210; chemical composition of, 210; development of, 211; functions of, 218; blood of, 219, 246, 264.
Splenic artery, 434; blood, 209, 219, 246, 263; uric acid in, 476.

Spring, on sensation, 704.
Squarey, Dr., on effects of coffee, 109.
Ssubotin, M., on alcohol, 107.
Stackmann, on quantity of bile, 166.
Städeler, on leucin, 75; on colouring matter of bile, 442 *note;* on excretion of urea, 480; on carbonaceous acids of urinary extractives, 478.
Stallions, weight of cerebellum in, 653.
Stammering, nature of, 839; treatment of, 844.
Stannius, his experiment on heart, 286.
Stapedius, functions of, 770.
Starch, a constituent of food. 83; its transformation by saliva, 137; by pancreatic fluid, 161; by intestinal fluid, 170; importance of, in protecting other tissues from the action of oxygen, 410; production of fat from, 414.
Stark, Dr., on chemical composition of bone, 49.
Starvation, effects of, 109; death by, 111; Chossat's experiments on, 111, 510, 511; acute, 111; slow, 114; treatment of, 511.
States of consciousness, 680.
Stature, influence of pulse on, 301.
Steapsin, 70, 461, 162.
Stefan, on ratio of liver weight to body weight, 433.
Stein, on erectile tissue, 340.
Steinberg, on quantity of blood, 223.
Steiner, on absorption of fat, 186; on effects of section of vagus, 365.
Steinhauser, on intestinal digestion, 171.
Steinheil, on perceptibility of different degrees of illumination, 759.
Steinmann, on velocity of blood current in arteries, 325; on venous circulation, 334.
Stercobilin, 477.
Stercorin, 90, 173.
Stereomonoscope, 741 *note.*
Stereoscope, 741; composite portraits, 743.
Sternum, development of, 947.
Stethometer, Sanderson's recording, 353.
Stewart, P., on animal heat, 500.
Stukitz, on date of appearance of catamenia, 877.
Stezinsky, on vaso-motor centre, 308 *note.*
St. George, Lavalette, on spermatozoa, 867 *note*, 870, 871, *note.*
St. Kilda, mortality at, 425.
St. Louis bridge, respiratory experiments during building of, 375.
St. Martin, case of, 145, 147, 148, 151.
St. Martin, Alexis, digestion in, 150.
Stich, on nerves implicated in sense of taste, 708, 712 *note.*
Stieda, M., on structure of spleen, 207; on corpuscula tactûs, 699 *note.*
Stilling, on erectile tissue, 340; on structure of spinal cord, 568 *note*, 570 *note;* nuclei of, 645; on optic tract, 720; on origin of third nerve, 581.
Stimuli, action of various, on nervous system, 548.
Stirling, on tetanus, 801.
Stoff, on spleen, 207.
Stokes, Prof. G., on cruorin, 235; on evolution of light, 519; on muscular contraction, 801; on spectrum analysis of the blood, 244.
Stomach, movements of, 121; action of, in vomiting, 124; influence of vagus on, 121, 154; influence of sympathetic upon, 155; lymphatics of, 145; secreting follicles of, 142–145; nerves of, 145; villous-like processes of, 142; secretion of gastric juice by, 144–147; digestion in, 145–158; temperature of, during digestion, 154.
Stomata of serous membranes, 197.
Strabismus, pathology of, 820.
Strasbürger, on cell growth, 34; on development of ova, 911.
Strassburgh, on hæmoglobin, 237.
Stratum zonale, 575.
Strauch, on respiration, 383.
Strauss, nervous mechanism of secretion of sweat, 491 *note.*
Strecker, on biliary acids, 441.
Strength, feats of, 821.
Stricker, Prof., on temperature of blood in heart, 224; on organisms in blood, 269 *note;* on vaso-motor centre, 308; on accelerator nerves, 296; on capillary circulation, 326; on contractility of capillaries, 328; in brain, 665 *note;* on milk, 972.
Strings, vibrating laws of, 766, 832.
Stroboscope, the, 835, 837.
Stroganow, on gases of blood, 259; on respiration in a confined space, 386.
Stroma of blood corpuscles, 234.
Stromuhr, Ludwig's, 324.
Strontium salts in bone, 415.
Strümpele, his case of anæsthesia, 684.
Strychnia, action of, on heart, 298 *note.*
Stuart, Prof. A., on ciliary movement, 782 *note.*
Sublingual gland, 138; secretion of, 135.
Sublobular veins, 435.
Submaxillary gland, 138; secretion of, 135; action of nervous supply, 138, 858; ganglion of sympathetic, 588, 849.
Suboccipital nerve, 584.
Subotin, on source of urea, 479 *note;* on formation of fat, 413, 414.
Succinic acid, 87; in urine, 469.
Succus entericus, 168; its use in digestion, 169.
Sucking, act of, 609; centre for, 611.
Sudoriparous glandulæ, number of, 489, 494; secretion, 489; characters of, 490; index of refraction for, 490; reaction of, 490; cause of, 490; loss by, 490; a true secretion, 490; nervous mechanism of, 491, 850; centre for, 491–493, 609, 611; influence of drugs upon, 491; causes modifying secretion of, 493, 495; influence of heat upon, 507; influence of nervous system on, 859; composition of, in health, 490; in disease, 491; quantity of, 492; vicarious with urinary, 494; consequences

of suppression of, 495; frigorifying effect of, 493; sensible, 490; insensible, 490.
Sugar, a constituent of the body, 84; formation of, in liver, 448, 450; passage of, into urine, after lesions of nervous system, 452; production of fat from, 414.
—— cane, 84.
—— grape, 84.
—— milk, 85.
—— muscle, 85.
Sulphates, alkaline, in urine, 468, 481.
Sulphocyanide of potassium in the saliva, 134.
Sulphuretted hydrogen gas, action of, on heart, 298 *note*; elimination of, by lungs, 384.
Sulphurous acid gas, effects of breathing, 359.
Superfecundation, 901.
Superfœtation, 901.
Superior laryngeal nerve, influence of, on respiration, 361.
Supernumerary parts, regeneration of, 427.
Supplemental air, 366.
Supra-renal bodies, structure of, 212; development of, 213, 938; function of, 218; effects of ablation of, 212; effects of disease of, 213.
Surface presented by lungs for aeration of blood, 369.
Sutschinsky, on action of Calabar bean on heart, 298 *note*.
Swallowing, act of, 118.
Sweat (see *Sudoriparous secretion*).
Sweat glands, 545; centre, 491, 493, 609, 611.
Swammerdam, on blood, 225.
Sylvius, fissure of, 658, 663.
Symonds, Dr., on death, 1022 *note*.
Symmetrical diseases, 280; movements, 817.
Sympathetic System (see *Nervous System*); ganglia of, 846; functions of, 540. 548; structure of rami communicantes, 598, 846, 847; myenteric ganglia of, 126; relation to cerebro-spinal system, 540.
Sympathetic columns of spinal cord, 565, fig.
Synaptase, 68.
Syncope, 116; death by, 1030.
Syntonin, 62; composition of, 59.
Syro-Arabian race, 998, 1000.
Szabadföldy, on fungiform papillæ, 709.
Szabó, on gastric juice, 146.

TACTILE corpuscles, 699; sensory nerves of, 698.
Tait, Lawson, on structure of umbilical cord, 927.
Tamamseheff, on structure of nerve-fibre, 523.
Tamulian language, 1002.
Tanghinia venenifera, action of poison of, on heart, 297.
Tanner, Dr. on a case of superfœtation, 902 *note*.
Tannic acid, action of solutions of, on blood corpuscles, 227.
Tappeiner, on reabsorption of bile, 446 *note*.
Tarchanoff, on influence of vagus on spleen, 211; on splenic blood, 219; on migration of white corpuscles, 333; on excretion of pigments of bile and blood, 442 *note*; on vagus, 295 *note*.
Tardieu and Roussin, on gastric juice, 146.
Taste buds, 710.
Taste, centres for, 675; nerves of, 590, 624, 708; sense of, 707; special conditions of, 711; seat of, 712; papillæ of, 710; varying acuteness of, 712; rapidity of, 713; participation of smell in, 707, 713; objects and uses of, 713; improvement of, by habit, 714; cases of loss of, 713 *note*; intensity of, 712; an instinct, 713.
Taurin, 81, 440, 449, 461; in urine, 469; quantity of sulphur in, 448.
Taurocholic acid, 82, 413, 441, 444, 445.
Taurylic acid in urine, 468, 478.
Taylor, Dr. A., on protracted gestation, 900 *note*; on age of fœtus, 1014 *note*; on eidoptometry, 733 *note*.
Tea, 109; influence of, on urine, 486.
Teale, Dr. J., his case of increased temperature in disease, 504, 505 *note*.
Teeth, structure of, 53; development of, 55, 1016; development of permanent, 1020.
Tegmentum, 631, 662.
Teichmann, on the lymphatics of the stomach, 145; on the lymphatic system, 194; on lymphatic glands, 193; on Peyerian glands, 199; on hæmin crystals, 237; on lymphatics of liver, 438; of muscle, 787 *note*.
Temperature, normal, of man, 498, 499; of infants, 499, 518; of aged persons, 500, 518; centre for, 676; special fibres for, 705; diurnal variation of, 500; effects of exercise on, 500, 798; artificial respiration on, 501; ingestion of food on, 502, 514; external heat and cold on, 502, 508, 509; disease upon, 504; moisture in air on, 507; on elimination of carbonic acid gas by lungs, 370; rise of, after death, 505; extremes of, endured by man, 498, 499, 506; sense of, 693, 702, 704, 779; of the blood in different parts of the body, 224; seasonal changes of, 503; influence of nervous system upon, 503, 507, 850; relation of, to pulse rate, 505; effect of inanition on, 510; influence of drugs upon, 516.
Tendon, structure of, 40, 41.
Tenner, on reflex action, 605.
Tension of aqueous vapour in air, 382; in expired air, 382; of oxygen in air, 381; in blood, 381; of carbonic acid in air, 381; in blood, 381.
Tension of muscles, influence of spinal cord on, 616.
Tensor tympani, functions of, 770.
Tergast, on nerves of muscle, 787.
Tesselated cells, 36.
Tessier, M., his cases of protracted gestation, 900.
Testes, structure of, 867; development of, 938; effects of stimulating, 618; nerves of, 868; lymphatics of, 868; development of

epididymis, 938 ; of gubernaculum, 938 ; of vasa deferentia, 937, 938 ; of vesiculæ seminales, 938 ; descent of, 938 ; ferment in, 69.
Tests for albuminous compounds, 60.
Tetano-motor, Heidenhain's, 549, 801.
Tetanus, 550, 793, 801 ; effect of, upon elimination of urea, 474.
Thackrah, Mr., on coagulation of blood in the vessels, 248.
Thalami optici, 618 ; their relation to the visual sense, 629 ; their functions, 629.
Thanhoffer, on nerves of villi, 179 ; on absorption of fats, 179.
Thaumatrope, 748.
Theatres, composition of air in, 393.
Theile, Prof., on hypospadias, 943 *note*.
Thein, action of, on heart, 298 *note ;* effect of, on urine, 486.
Thin, Dr., on globular richness of blood, 225 ; on corpuscula tactûs, 699 *note*.
Third pair of nerves, 581, 588, 722.
Thirst, immediate source of sense of, 111 ; death by, 112.
Thiry, M., on intestinal juice, 169 ; on blood crystals, 235 ; on innervation of heart, 293 ; on vaso-motor centre, 308 ; on Traube's curves, 310 ; on dyspnœa, 359 ; on respiration, 383, 387.
Thomas, on migration of white corpuscles, 332.
Thompson, Dr., on diagnosis of myopia and presbyopia, 727.
Thomsen, on temperature of Icelanders, 499.
Thomson, Prof. A., on micropyle, 886 ; on development of embryo, 910, 912 *note*, 942 ; on origin of mesoblast, 914 *note ;* on blastoderm, 917 *note*.
——— Dr. Murray, on cutaneous absorption, 190.
Thoracic duct, change of corpuscles in, 252.
Thornley, on influence of climate upon temperature, 499 *note*.
Thudichum, Dr. J. L. W., on lutein, 74 ; on Liebig's extract of meat, 95 ; on blood crystals, 239 ; on colouring matter of bile, 442 *note ;* on urine, 466 *note*, 468 *note ;* on hippuric acid, 476 ; on urinary pigments, 478 *note ;* on chemistry of nerves, 529.
Thurnam, on weight of brain, 664 *note*.
Thurston, on systole of heart, 288 *note*.
Thury, M. Marc, on the cause of difference of sex, 961.
Thymus gland, structure and development of, 213–216 ; function of, 218.
Thyroid gland, chemical constituents of, 216 ; structure of, 216 ; development of, 217 ; function of, 218, 829 *note*.
Tibbitts, on uræmia, 463 *note*.
Tickling, sense of, 704.
Tidal air, 366.
Tiedemann and Gmelin, MM., on gastric juice, 146 ; on absorption from alimentary canal, 184 ; on glands of Bartholin, 880 *note*.
Tieffenbach, on diabetes, 454.
Tiegel, on ferment in blood, 255 ; on glycogeny, 449.
Tigger, on action of heat on heart, 288 *note*.
Timbre, cause of, 761, 842.
Tissue-albumin, 204.
Tobacco, influence of, on body, 108, 487.
Todaro, on structure of nerve fibres, 526 *note*.
Tod, Mr., on duration of irritability of heart, 276.
Todd and Bowman, on structure of mucous membrane of stomach, 145 ; on structure of liver, 434 ; on peculiar excitability of frog, 603 *note ;* on muscular tension, 626 ; on corpora striata and thalami optici, 619 ; on functions of mesocephalon, 633 ; on papillæ of tongue, 708, 709 ; on olfactory nerve, 715 ; on nerves of taste, 590.
Toldt, on adipose tissue, 47 ; on Brünner's glands, 168 ; on erectile tissue, 340 ; on kidney, 457 ; on neuroglia, 568.
Tolmatscheff, on chemical composition of milk, 972.
Tomes, Mr., on removal of bone by absorption, 419.
Tommasi, Prof., on influence of altitude on pulse, 302.
Tomsa, on lymph, 205 ; on lymphatics of spleen, 210 ; on tactile corpuscles, 699 *note*.
Tone of muscle, 616.
Tones, causes of, 760.
Tongue, papillæ of, 709–714 ; sensory nerves of, 590, 708 ; motor nerves of, 594 ; sensibility of, 701 (see *Taste*).
Tooth germs, 56.
Török, Von, on structure of nerve fibre, 523.
Touch, ganglia of, 675 ; nerves of, 598, 698 ; sense of, 698 ; papillæ of, 698 ; centre for, 675 ; varying acuteness of, 700 ; theory of sense of, 701 ; duration of impression of, 705 ; improvement of, by practice and attention, 706 ; combination of, with visual sense, 706, 738 ; influence of spinal cord on sense of, 608 ; of drugs on, 702 ; discrimination of colours by, 707.
Towne, Mr., on the stereoscope, 623 *note*, 743 *note ;* on partial amaurosis of the retina, 623, 739.
Towns, composition of air in, 393.
Townsend, Col., case of, 1024.
Toynbee, Mr., on structure of kidney, 456 *note ;* on membrana tympani and its muscles, 769, 771.
Trabeculæ, directing, of bone, 52.
Trachea, pressure of air in, 838.
Traill, Dr., on fat in the blood, 268.
Trainers, diet of, 104 *note*.
Transparent colourless corpuscles of blood, 234.
Trapezium in medulla, 573 *note*.
Traube, M., on action of carbonic oxide on heart, 298 *note ;* his curves of arterial pressure, 310, 323 ; on effects of section of vagus, 365 ; on uræmia, 463 *note ;* on respiration of poisonous gases, 385.
Tricuspid valve, imperfect closure of, 280.

Trifanowski, on amount of sulphur in taurin, 440.
Trigeminus, 580 (see *Fifth Pair*).
Triolein, 88.
Tripalmitin, 88.
Tristearin, 88.
Troitzky, on velocity of motor impulses, 552.
Trommer, on milk, 974 *note*.
Trophic nerves, 847, 854.
Trotter Coutts, on orifices of heart, 281 *note*.
Trousseau, M., on suspended lactation, 970 *note*.
Truchot, on elimination of ammonia, 383.
Truhart, on action of poisons on heart, 293 *note*.
Trümpy, on reaction of sweat, 490 *note*.
Trütschel, on nerves of stomach of frog, 145.
Trypsin, 69, 161.
Trypsinogen, 70.
Tschaussow, on movements of pigment cells, 39.
Tscherinoff, M., on glycogeny, 449, 455.
Tscheschichin, M., on temperature of the body, 502, 503 *note*, 504.
Tschirjew, on inhibitory centres, 303 *note*.
Tuber annulare, effects of section of, 632; effects of electric current on, 632.
Tubercula quadrigemina, 617, 626.
Tuberculum cinereum, 575.
——— cuneatum, 575.
Tunica vaginalis, structure of, 196.
Türck, Dr., on pathological changes in spinal cord, 571.
Turkish race, 998.
Turley, Mr., his case of excessive sexual desire, 655 *note*.
Turner, Prof., on bronchial system of vessels, 347; on arrangement of convolutions of brain, 658 *note;* on placenta, 887, 890 *note*.
Tympanic apparatus, structure and uses of, 771 (see *Hearing, Organ of*).
Tympanograph, 772 *note*.
Tyndall, Prof., on germs in air, 428; on sound, 760, 770 *note;* on odorous substance, 715 *note*.
Typical vertebra of Owen, 947.
Tyrosin, 75, 163, 412, 461, 469.
Tyson, on glycogeny, 456 *note;* on kidney, 461.

ULOTRICHI, 986.
Umbilical cord, structure of, 926; vessels, 926; vesicle, 921.
Unorganized ferments, 68.
Unzer, Prof., on reflex action, 606.
Upas antiar poison, action of, on heart, 297.
Urbantschitsch, on "deaf-spots," 775.
Urachus, 925.
Uræmia, pathology of, 462.
Urari, poison, influence of, on secretion of saliva, 141; on urine, 466; action of, on heart, 297, 298 *note;* action of, on animal heat, 507, 516; effect of, on motor nerves, 803.
Urea, 80, 461, 469; influence of season upon quantity excreted, 470; proportion eliminated to body weight, 470 *note;* influence of sex upon quantity excreted, 471; influence of exertion upon, 472; effect of tetanus upon, 474; effect of leucin and tyrosin upon excretion of, 474; influence of frequency of micturition upon, 474; in muscle, 789; in sweat, 490; of muscular exertion on, 824; in disease, 475; mode of origin of, 478; effects of acids and alkalies upon, 479; place of origin of, 463, 464, 478, 479, 481; its ordinary proportion in urine, 468; circumstances affecting quality of, 375, 418, 463, 478; its presence in blood, 470, 479; in expired air, 383; consequences of its non-elimination, 463.
Ureter, development of, 936.
Uric acid, 80; its ordinary proportion in urine, 468, 475; variations in its amount, 470; circumstances modifying quantity of, 475; sediments produced by, 476; its occurrence in various diseases, 476; sources and mode of origin of, 478.
Urinary organs, development of, 934–938; bladder, development of, 938.
Urination, act of, 131, 465, 474, 488.
Urine, 463–488; index of refraction for, 464; morphological elements of, 464; influence of blood pressure on secretion of, 465, 466; influence of nerve supply on, 466; in morbid conditions, 466; fermentation of, 467; ferments in, 469, 488; variations of, amongst European nations, 468 *note;* pigment in, 468; extractives of, 469, 478; luminosity of, 520; abnormal constituents of, 469, hippuric acid in, 476; odour of, 478; secretion of, 456, 463, 465; excrementitious character of, 463, 486; physical properties of, 464; quantity of, 465; circumstances affecting quantity, 465; specific gravity of, 464, 467; composition of, 405, 468; colouring matter of, 477, 478; gases contained in, 483; differences of, with age, 465, 467; influence of diet on, 464, 485, 486; influence of diuretic medicines on, 466, 471, 487; organic components of, 468 (see *Urea, Uric Acid*, &c.); acidity of, 464, 469; alkalinity of, 464, 476, 485; inorganic components of, 468, 476, 481; sugar in, 452, 464, 468; lactic acid in, 469; vicarious secretion of, 431; albumin in, 461, 462.
Uriniferous tubules, 457; functions of various parts of, 461.
Urobilin, 442 *note*, 478.
Urochrom, 478 *note*.
Uro-genital sinus, 937, 941.
Uromelanin, 478 *note*.
Uropittin, 478 *note*.
Urrhodin, 76.
Uschakoff, on perimetry, 724 *note*.
Uspensky, on reflex action, 605.
Ustimowitsch, on renal circulation, 465 *note*, 466.
Uterine glandulæ, 887.

Uterus, inherent motility of, 894, 895 *note;* increase of, during pregnancy, 893; innervation of, 894; action of, in parturition, 896; temperature of, in parturition, 509 *note;* subsequent degeneration of, 420, 897; embryonic development of, 940; rudimentary, of male, 940; changes in, during gestation, 887, 893; structure of mucous membrane, 887 *note.*
——— bicornis, 941.
Utriculus, 763.

VAGINA, development of, 940.
Vagus nerve (see *Pneumogastric Nerve*).
Valentin, Prof., on pulmonary exhalation of aqueous vapour, 382; on amount of fæces, 406; on refraction of blood, 224; on influence of external cold on temperature, 503 *note;* on movements of stomach, 123; on pancreatic juice, 161; his estimate of amount of blood, 222 *note;* on amount of blood discharged from heart, 299; on rate of blood's movement in capillaries, 329; on erectile tissue, 340; on excitability of mucous surface of trachea and bronchi, 355, 362; on quantity of air respired, 367; on cutaneous respiration, 495; on glosso-pharyngeal, 590; on hypoglossal, 594; on cephalic nerves generally, 595; on olfactory nerves, 620, 718; on behaviour of spinal cord in regard to electric currents, 596; on sense of touch, 701, 704; on sense of taste, 712; index of refraction for bile, 443; for sweat, 490; for milk, 970; on optic nerve, 621.
Valerianic acid, 89.
Valsalva, experiment of, 281.
Valve of Vieussens, 581.
Valves of heart, 273; action of, 279, 280.
Van Beneden, on ova previous to fertilization, 885 *note.*
Van Helmont, on action of intercostals, 353.
Vance, on encephalic circulation, 339.
Vanlair, on pigments of bile and urine, 477; on spinal cord, 601.
Vanner, his estimation of the quantity of blood, 222.
Vanzetti, on trophic nerves, 817.
Vao poison, action of, on heart, 297.
Vapour, aqueous, absorption of, 190.
Variation, tendency to, 983, 992.
Varieties of Man, their essential conformity in structure, 981; in physiological characters, 990, 992; in psychical endowments, 990; in languages, 996 (see *Races*).
Varnishing, 493, 512.
Vas aberrans, structure of, 868.
Vas deferens, 869, 937, 939, 941.
Vascular area, 918, 920; glands, 206; system, development of, 920.
Vasey, on locomotion, 815.
Vaso-constrictor fibres, 588, 852.
Vaso-dilatator fibres, 588.
Vaso-inhibitory fibres, 294.
Vaso-motor centre, 309, 578, 610, 611, 651, 676.
Vaso-motor nerves, 305, 308, 592, 595, 598, 623, 807, 847, 848, 951.
Veddahs, 1003 *note.*
Vegetable cell, 34; globulin, 63; myosin, 63; vitellin, 64.
Vegetables, fresh, an essential article of diet, 99.
Vegetarianism, 97.
Veins, structure of, 333; movement of blood in, 333; causes of motion of blood in, 335; congestion in, 336; development of first set, 921; of second set, 928.
Vena portæ, 435.
Venous blood, differential characters of, 261–264; causes of variation of colour in, 261; influence of, on intestines, 129; on respiration, 385; murmur, 337; pulse, 281.
Ventilation, 392.
Ventricle of heart, effect of pregnancy on left, 273; systole of, 278; blood pressure in, 321.
Veratria, section of, on heart, 298 *note.*
Verloren, M., on derivation of force from farinaceous compounds, 418, 825.
Verson, on structure of villi, 181; on structure of thyroid body, 216.
Vertebra, typical, 947; cranial, 949; development of, 946.
Vertebral column of man, comparison of, with that of apes, 26; first indications of, 944.
Vesalius, on action of intercostals, 352; on optic chiasma, 623 *note;* 885 *note.*
Vesico-spinal centre, 609.
Vesicula prostatica, its real import, 940, 942.
Vesiculæ seminales, function of, 869; development of, 938.
Vesling, on intercostals, 352.
Vessels, blood, development of, 920.
Vestibule of ear, 763.
Vestigial fold of Marshall, 929.
Viability, early, of fœtus, 899, 962; relative, of two sexes, 963, 1024.
Vibrations in instruments, 833.
Vibriones, action of, in fermentation, 66.
Vicarious secretion, 431.
Vierordt, on food, 101; on quantity of blood, 222; on globular richness of blood, 225; on amount of blood expelled by ventricles, 299; his hæmatochometer, 324; on rate of circulation in arteries, 324; in capillaries, 329; on respiratory movements, 329, 350; on amount of tidal air, 367; on percentage of carbonic acid in expired air, 369; on circumstances affecting this, 370; on pulmonary exhalation, 382; on work performed by body, 417; on spectrum notation, 240, 442 *note;* on tactile sensibility, 702; on rapidity of accommodation, 724; on regeneration of nerves, 529.
Vignal and Rutherford, on drugs influencing flow of bile, 447.
Villermé, M., on influence of season on mortality of children, 518.

Villi, intestinal, structure of, 178; rudimentary of stomach, 142; of placenta, 890.
Vintschgau, on sense of taste, 712, 713.
Virchow, Prof., R., on development of connective tissue, 42; on blood crystals, 239; on connective tissues, 328; on origin of pus cells, 331; on giant cells, 419; on fatty degeneration of uterus after parturition, hæmatoidin crystals, 441; on the relation between the colouring matter of blood and bile, 442 *note;* on corpora amylacea, 451; on neuroglia, 568, 730; on cerebrum, 664; on muscle, 807.
Visceral system of nerves, 845.
Vision, ganglia of, 720; centre for, 675; nerves of, 717, 720; sense of, 737; optical conditions of, 719; defects in, 717, 721; accommodation of, for varying distances of objects, 722; conditions of distinct, 725; Scheiner's experiment, 726; influence of drugs on accommodation, 727; astigmatism, 727; hypermetropia, 726; myopia, 727; ametropia, 726; purple, 730; acuteness of, for lines, 734; for points, 734; for light, 734; effect of attention on, 734; sense of direction, 738; nervous apparatus of, 728–733; limits of, 733; use of, in combination with touch, 737; erect, cause of, 738; single, conditions of, 739; appreciation of solid forms by, 740; of distances, 743; of size, 744; conversions of relief, 744, 747; persistence of impressions, 748; complementary colours, 749; coloured shadows, 752; acuteness of perception for colours, 751, 752; rapidity of perception, 778; want of power to distinguish colours, 752, 753; irradiation of impressions, 752; vanishing of images, 756; perception of laterally situated objects by, 755; recurrent vision, 752; extent of field of, 724; emmetropic, 724; acuteness of 733; sense of direction, 838; perspective, 744; visual angle, 744; imperfect perceptivity of optic disk, 755; visualisation, 758; subjective phenomena of, 757; electrical current induced by light, 756; phosphènes, 757; representation of vessels of retina itself, 757; improvement of, by attention, 758; importance of, in guiding movement, 817; appreciation of varying amounts of illumination by, 754; of objects at great distances, 757.
Visualisation, 758.
Visual purple, 730; bleaching of, 730; action of reagents on, 730, 731; influence of light on, 731.
Vital activity, distinctive characters of, 2.
—— capacity, 366; effects of height and weight on, 366.
—— economy, balance of, 402–419; with ordinary diet, 404; in inanition, 406; with pure meat diet, 409; with meat and fat, 410; with sugar and meat, 410; differences between carnivora and herbivora, in respect to, 410; changes undergone by fat in maintaining, 413; changes undergone by sugar and starch in maintaining, 414; application of inorganic constituents of the food to maintenance of, 415; work done in and by the body, 416; substitution of new tissue for old in, 421; necessity of due supply of nervous power for maintenance of, 421.
Vitalist theory of fermentation, 65.
Vitellin, animal, 64; vegetable, 64.
Vitelline duct, 916, 921; vessels, 921; membrane, 910, 940.
Vitellus, 910; its segmentation, 911.
Vivenot, on effects of compressed air on heart, 375.
Vocal apparatus, movements of, 638.
Vocal chords, 826, 828; vocal ligaments, 832 (see *Larynx, Glottis, Chordæ Vocales, Articulate Sounds*).
Vogel, on the urine in disease, 475.
Vogt, his cases of paralysis of fifth pair, 590.
Voice, ordinary mode of production, 835, 838; nerves of, 593, 642; influence of optic thalami on, 629; regulation of, by the hearing, 778; structure of larynx, 827 (see *Larynx*); modifications of, 835; falsetto, 836; pressure of air in trachea during production of, 838; limits of, 838; in deaf persons, 839.
Voit, Prof., on movement of air, 392; on amount of nitrogen in fæces, 406; on action of bile on fats, 162; on quantity of bile, 167; on rectal absorption, 188; on quantity of biliary acids, 174; on respiratory movements, 353; on elimination of carbonic acid, 372; on elimination of nitrogen, 381; on nutrition, 402; on uræmia, 463 *note;* on origin of urea, 471, 472, 481; on influence of coffee on urine, 487 *note;* on effects of removal of cerebrum, 626; on hippuric acid, 477; on luxus consumption, 479 *note.*
Volition, fixation of attention by, in states of dreaming and somnambulism, 692; of spinal cord, 607.
Volitional actions, their source in the cerebrum, 538, 539.
Volkmann, Prof., on cardiac poisons, 298 *note;* on amount of blood discharged from heart, 299; on the influence of stature on the pulse, 301; on dilatation of arteries with pulse-wave, 311; his hæmodromometer, 323; on rate of movement of blood in arteries, 324; on rate of blood's movement in capillaries, 329; on contractility of lungs, 347; on intercostal muscles, 353; on discrimination of sensory impressions, 543; on spinal cord, 573; on improvability of sense of touch, 706; on phenomena of exhaustion in muscle, 793 *note;* on perceptibility of different degrees of illumination, 756, 759; elasticity of muscle, 779, 795 *note.*
Voluntary movements, their dependence on guiding sensations, 557, 640; performed

by instrumentality of sensori-motor apparatus, 640; not in themselves distinguishable from involuntary movements, 643; but result from an impulse originating in cerebrum, 539.
Vomiting, act of, 121; centre for, 611.
Vrolik, Prof., on the quadrumana, 22; on varieties in form of pelvis, 991.
Vowel sounds, 761, 831; discrimination of, 839; artificial production of, 761, 841.
Vulpian, M., on action of curare on heart, 298 *note;* on vaso-motor nerves, 308, 310, 852 *note;* on contractility of capillaries, 328; on helicine arteries, 340; on rhythmical contraction of veins, 335; on nerve regeneration, 528, 543 *note;* on chorda tympani, 586; on glosso-pharyngeal nerve, 590; on hypoglossal nerve, 594, 595; on presence of taurocholic acid in adrenals, 444; on allantois, 925; on spinal accessory, 593; on nervous mechanism of secretion of urine, 466; of sweat, 491, 859; on cerebellum, 647 *note;* on trophic fibres, 854, 856, 858.

WADE, Sir C., his case of trance, 1032 *note.*
Wagener, on muscle, 784 *note.*
Wagner, on fatty degeneration, 201; on number of blood corpuscles, 233; on accelerator nerves, 296; on rhythmical contraction of veins, 335; on resections, 427; on the cerebellum, 646 *note;* on tactile papillæ, 647, 649, 699; on spermatozoa, 871 *note;* on cerebrum, 661; on taste, 709; on nervous supply of iris, 735 *note.*
Waldeyer, Dr., on teeth, 57; on lesion of semicircular canals, 628 *note;* on cochlea, 764 *note;* granular layer of, 765; on ovaries, 874, 939, 940 *note;* on vision, 719 *note;* on structure of tendon, 41.
Walker, Mr. A., on intermarriage, 902 *note;* on rigor mortis, 810.
Walkhoff, on causes of closure of ductus arteriosus, 931 *note.*
Walking, work done in, 418; movements executed in, 646, 813.
Wallace, Mr. Alf. Russell, on the fauna of the Malay Archippelago, 1008 *note.*
Waller, Dr. Aug., on migration of white corpuscles, 266, 331; on effects of section of nerves on their structure, 847; on regeneration of nerve structure, 529, 615 *note;* on influence of sympathetic on walls of arteries, 307, 516; on effects of division of the sympathetic, 850; on ending of gustatory nerves, 710 *note;* on decussation of the optic nerves, 739 *note;* on emigration of white corpuscles, 331.
Walter, on influence of acids upon excretion of urine, 483.
Walther, Dr., on death by cold, 506, 509.
Walton, on deglutition, 119.
Ward, Mr. N. B., on post-mortem movements in cholera patients, 809.
Wardrop, Mr., on influence of passion on mammary secretion, 861 *note.*
Warnecke, on urea, 471 *note;* in disease, 475.
Wartmann and Seebeck, on Daltonism, 754 *note.*
Wasmann, on pepsin, 147.
Water, proportion of, in different fluids and solids, 90; the natural drink of man, 105; effects of drinking large quantities of, 106; effects of impurity of, 106; effects of deprivation of, 112: normal proportion of, in blood, 254; alterations in, 268; exhalation of, through lungs, 382; quantity of, required daily, 402; proportion of, eliminated by different channels, 410, 111; gases in, 343; transudation of, by kidney, 465.
Waters, Dr., on the structure of the lungs, 345; a cause of respiratory murmur, 354.
Watney, on lymphatics of stomach, 145; on villi, 179, 182; on the thymus, 214, 215.
Watson, Dr., on absorption of vapour, 190.
Watson, Prof., on homologies of sexual organs, 941, 942, 943.
Waxy degeneration, 73.
Weber, Profrs., on quantity of blood, 223; on arrest of heart's action by stimulating the vagi, 290; on rate of pulse wave, 316; on diameter of capillaries, 327; on erectile tissue, 340; on structure of liver, 437; on perceptivity of nerves for heat, 550; on size of pulmonary air-cells, 346; on tactile papillæ, 700; on tactile sensibility, 701; on appreciation of weight, 703; on appreciation of temperature, 704; on sensibility of tongue, 701, 709; on special conductors for temperature, 705; on perception of sounds, 766, 777; on elasticity of muscle, 795; on centre of gravity of the body, 813; on mechanical power of muscle, 821; on sounds of vibrating reeds, 833; on vesicula prostatica, 941 *note,* 943; on varieties of form of pelvis, 991; on measurement of sensation, 778.
Wedl, on lymphatics of spleen, 210; lymphatics of liver capsule, 439 *note.*
Wegscheider, on fæces of infants, 173.
Weigelin, M., on excretion of urea after exertion, 474.
Weight, appreciation of, 703, 779; lifting of, 821.
Weikart, on urea, 470.
Weil, on action of digitalis in increasing reflex excitability, 605.
Weiske, on salts of bones, 50, 415; on formation of fat, 414; on source of urea, 479 *note.*
Weiss, on glycogen in muscle, 85; in embryo, 456; in liver, 450, 455; on relative capacity of ventricles of heart, 274; on quantity of lymph, 200; on the rate of its movements, 206.
Weissmann, on hippuric acid, 476.
Welcker, on size of red corpuscles, 226; on extent of respiratory surface, 369.

Wells, Dr. J. Soelberg, on the eye, 724 *note*,
——— Dr., on colour of blood, 261.
Wendt, on lymphatics of liver, 439
Wernicke, on effects of heat on heart, 288 *note*.
Wertheim, on structure of nerve, 526 *note*.
West, Van, on rapidity of motor impulses, 553.
Weston, Mr., experiments made on, during exercise, 474, 481, 482.
Westphalen, on quantity of bile, 166.
Weyland, on action of various poisons on heart, 298 *note;* on muscular contraction, 802.
Weyl, on vitellin, 64.
Weyrich, on temperature of expired air, 369; on insensible perspiration, 376, 492; on tension of watery vapour in expired air, 382.
Whales, provision for storage of oxygen in, 387.
Wharton s jelly, structure of, 927.
Wheatstone, Prof., on binocular vision, 740–743; on falsetto voice, 836.
Whewell, Prof. W., on astigmatism, 727.
White, Mr., his case of reproduction of supernumerary thumb, 427 *note*.
White corpuscles, 231 (see *Blood, Colourless Corpuscles*).
White substance of Schwann, 524, 525.
Whitehead, Mr., on menstrual fluid, 878.
Wiederhold, on composition of expired air, 383.
Wiegandt, on cells of villi, 182.
Wieland, on hermaphrodism, 942 *note*.
Will, the, relation of, to cerebro-spinal system, 540.
Willan, on abstinence, 116.
Willemin, on cutaneous absorption, 190.
Williams, Dr. C. J. B., on destruction of blood corpuscles, 267; on force required to propel the blood, 271; on sounds of heart, 283; on venous circulation, 336; his experiments on the tonicity of blood-vessels, 336; on contractility of bronchial tubes, 347, 348; on animal heat, 501; on death from necræmia, 1031 *note;* on proximate causes of death, 1032 *note*.
———— on structure of uterine mucous membrane, 887 *note*.
Willis, Dr., on functions of cranial nerves, 544, 594.
——— Mr., his artificial glottis, 834; on vowel sounds, 842.
Wilson, Mr. E., on sudoriparous glands, 489, 490.
Winiwarter, on cochlea, 764 *note*.
Winking, 612.
Winkler, on cardiac muscle, 784 *note*.
Winogradoff, on diabetes, 454.
Winslow, on relative capacity of ventricles of heart, 273; on action of intercostals, 352.
Winternitz, on temperature of viscera, 438.
Wintrich, on influence of vagus on lungs, 348; on heart sounds, 284.
Wintringham, on resistance of aorta to pressure, 333.
Wislicenus and Fick, MM., on excretion of nitrogen of the urine, 472.
Wistinghausen, on influence of bile in promoting absorption, 186.
Wittich, Von, on ferments, 69; on bile, 166, 441, 443, 451; on kidney, 461; on glycogeny, 449; on vaso-motor nerves, 852 *note;* on hearing, 778, note.
Wohler, on excretion of soluble salts, 486.
Woinlow, on perception of colour by retina, 755 *note*.
Wolff, on osseous tissue, 47; on development of vessels, 920 *note*.
Wolffian bodies, 935, 945; duct, 456, 935–937; blastema, 935.
Wollaston, Dr., on the sound accompanying muscular contraction, 794; on appreciation of sounds, 760.
Wood, on action of veratria on heart, 298 *note*.
——— Sam., on hermaphrodism, 943.
Woodfield, on nervous mechanism of secretion of sweat, 471.
Woodward, Dr., on blood corpuscles, 229 *note*.
Woorara poison (see *Curare, Urari*).
Work done in and by the body, 417.
Worm-Müller, on effects of injection of blood, 223; on blood pressure, 321.
Wrisberg, on quantity of blood, 222; on descent of testes, 938.
Wunderli, on sensation of heat, 705.
Wunderlich, on evolution of heat, 501, 506; on post-mortem rise of temperature, 506; on local variations of temperature in disease, 516; on normal temperature, 498, 499.
Wundt, on action of oxygen on heart, 287; on influence of curare on heart, 296; on elasticity of arteries, 305 *note;* on influence of respiration on blood pressure, 322; on Traube's curves, 323; on action of intercostal muscles, 352; on electrical phenomena in nerves, 549, 554 *note;* on elasticity of muscle, 795; destination of glycogen, 456.
Wyman, Jeffries, on force of ciliary movement, 781 *note*.
Wyss, O., on biliary ducts, 437 *note;* on Fechner's formula, 778–780.
Wywodzoff, M., on lymphatics of lungs, 193, 347.

XANTHIN, 78, 461, 468, 469, 478 *note;* in nerve, 530.

YAWNING, act of, 363.
Yeast, action of, in fermentation, 66.
Yellow fever, elevation of temperature after death from, 506; immunity of negroes from, 994 *note;* movements after death from, 809.
——— spot of retina, 731, 755.

Yolk of egg, of fowl, structure of, 866, 909; of fish, rotation of, 780; white, 910; yellow, 910.
Young, Dr., on fundamental colours, 749; on vision, 752.
Youth, characteristics of, 1017, 1022.

ZALESKY, M., on origin of urinary constituents, 479 *note*.
Zahn, on milk, 972.
Zanarelli, on fat in the blood, 268.
Zawarykin, on blood crystals, 239.
Zawerthal, on structure of nerves, 525 *note*.
Zenker, on the relation between the colouring matter of blood and bile, 442 *note*.
Zimmerman, on effects of loss of blood, 258.
Zoamylin, 449.
Zöllner, M., example of optical illusion, 748.
Zona glomerulosa, 212; fasciculata, 212; reticularis, 212; pellucida, 876, 940.
Zooid, 227.
Zuckerkandl, on the Eustachian tube, 771 *note*.
Zuntz, on influence of respiration on blood pressure, 322; on animal heat, 508 *note*; on oxygen in fœtal blood, 931.
Zymogen, 70.
Zymotic poisons from deficiency of respiration, 394.

THE END.

SELECTION

FROM

J. & A. CHURCHILL'S GENERAL CATALOGUE

COMPRISING

ALL RECENT WORKS PUBLISHED BY THEM

ON THE

ART AND SCIENCE OF MEDICINE

N.B.—As far as possible, this List is arranged in the order in which medical study is usually pursued.

A SELECTION

FROM

J. & A. CHURCHILL'S GENERAL CATALOGUE,

COMPRISING

ALL RECENT WORKS PUBLISHED BY THEM ON THE ART AND SCIENCE OF MEDICINE.

N.B.—*J. & A. Churchill's Descriptive List of Works on Chemistry, Materia Medica, Pharmacy, Botany, Photography, Zoology, the Microscope, and other Branches of Science, can be had on application.*

Practical Anatomy:
A Manual of Dissections. By CHRISTOPHER HEATH, Surgeon to University College Hospital. Fifth Edition. Crown 8vo, with 24 Coloured Plates and 269 Engravings, 15s.

Wilson's Anatomist's Vade-Mecum. Tenth Edition. By GEORGE BUCHANAN, Professor of Clinical Surgery in the University of Glasgow; and HENRY E. CLARK, M.R.C.S., Lecturer on Anatomy at the Glasgow Royal Infirmary School of Medicine. Crown 8vo, with 450 Engravings (including 26 Coloured Plates), 18s.

Braune's Atlas of Topographical Anatomy, after Plane Sections of Frozen Bodies. Translated by EDWARD BELLAMY, Surgeon to, and Lecturer on Anatomy, &c., at, Charing Cross Hospital. Large Imp. 8vo, with 34 Photolithographic Plates and 46 Woodcuts, 40s.

An Atlas of Human Anatomy.
By RICKMAN J. GODLEE, M.S., F.R.C.S., Assistant Surgeon and Senior Demonstrator of Anatomy, University College Hospital. With 48 Imp. 4to Plates (112 figures), and a volume of Explanatory Text, 8vo, £4 14s. 6d.

Surgical Anatomy:
A Series of Dissections, illustrating the Principal Regions of the Human Body. By JOSEPH MACLISE. Second Edition. 52 folio Plates and Text. Cloth, £3 12s.

Medical Anatomy.
By FRANCIS SIBSON, M.D., F.R.C.P., F.R.S. Imp. folio, with 21 Coloured Plates, cloth, 42s., half-morocco, 50s.

Anatomy of the Joints of Man.
By HENRY MORRIS, Surgeon to, and Lecturer on Anatomy and Practical Surgery at, the Middlesex Hospital. 8vo, with 44 Lithographic Plates (several being coloured) and 13 Wood Engravings, 16s.

Manual of the Dissection of the Human Body. By LUTHER HOLDEN, Consulting Surgeon to St. Bartholomew's and the Foundling Hospitals, and JOHN LANGTON, F.R.C.S., Assistant Surgeon and Lecturer on Anatomy at St. Bartholomew's Hospital. Fourth Edition. 8vo, with 170 Engravings, 16s.

By the same Author.

Human Osteology:
Sixth Edition, edited by the Author, with the assistance of JAMES SHUTER, F.R.C.S., M.A., M.B., Assistant Surgeon to the Royal Free Hospital. 8vo, with 61 Lithographic Plates and 89 Engravings. 16s.

Also.

Landmarks, Medical and Surgical. Third Edition. 8vo, 3s. 6d.

The Student's Guide to Surgical Anatomy: An Introduction to Operative Surgery. By EDWARD BELLAMY, F.R.C.S. and Member of the Board of Examiners. Fcap. 8vo, with 76 Engravings, 7s.

The Student's Guide to Human Osteology. By WILLIAM WARWICK WAGSTAFFE, Assistant Surgeon to St. Thomas's Hospital. Fcap. 8vo, with 23 Plates and 66 Engravings, 10s. 6d.

The Anatomical Remembrancer; or, Complete Pocket Anatomist. Eighth Edition. 32mo, 3s. 6d.

Diagrams of the Nerves of the Human Body, exhibiting their Origin, Divisions, and Connections, with their Distribution to the Various Regions of the Cutaneous Surface, and to all the Muscles. By WILLIAM H. FLOWER, F.R.C.S., F.R.S., Hunterian Professor of Comparative Anatomy to the Royal College of Surgeons. Third Edition, with 6 Plates. Royal 4to, 12s.

Atlas of Pathological Anatomy. By Dr. LANCEREAUX. Translated by W. S. GREENFIELD, M.D., Professor of Pathology in the University of Edinburgh. Imp. 8vo, with 70 Coloured Plates, £5 5s.

A Manual of Pathological Anatomy. By C. HANDFIELD JONES, M.B., F.R.S.; and EDWARD H. SIEVEKING, M.D., F.R.C.P. Edited (with considerable enlargement) by J. F. PAYNE, M.D., F.R.C.P., Lecturer on General Pathology at St. Thomas's Hospital. Second Edition. Crown 8vo, with 195 Engravings, 16s.

Lectures on Pathological Anatomy. By SAMUEL WILKS, M.D., F.R.S., Physician to Guy's Hospital; and WALTER MOXON, M.D., Physician to Guy's Hospital. Second Edition. 8vo, with Plates, 18s.

Post-Mortem Examinations: A Description and Explanation of the Method of performing them, with especial reference to Medico-Legal Practice. By Prof. VIRCHOW. Translated by Dr. T. P. SMITH. Second Edition. Fcap. 8vo, with 4 Plates, 3s. 6d.

Principles of Human Physiology. By W. B. CARPENTER, C.B., M.D., F.R.S. Ninth Edition. By HENRY POWER, M.B., F.R.C.S. 8vo, with 3 Steel Plates and 377 Wood Engravings, 31s. 6d.

A Treatise on Human Physiology. By JOHN C. DALTON, M.D., Professor in the College of Physicians and Surgeons, New York. Sixth Edition. Royal 8vo, with 316 Engravings, 20s.

Text-Book of Physiology. By J. FULTON, M.D., Professor of Physiology, &c., in Trinity Medical College, Toronto. Second Edition. 8vo, with 152 Engravings, 15s.

Practical Histology. By WILLIAM RUTHERFORD, M.D., F.R.S. Third Edition. Crown 8vo, with Engravings. (*Preparing.*)

Sanderson's Handbook for the Physiological Laboratory. By E. KLEIN, M.D., F.R.S.; J. BURDON-SANDERSON, M.D., F.R.S.; MICHAEL FOSTER, M.D., F.R.S.; and T. LAUDER BRUNTON, M.D., F.R.S. 8vo, with 123 Plates, 24s.

Histology and Histo-Chemistry of Man. By HEINRICH FREY, Professor of Medicine in Zurich. Translated by ARTHUR E. J. BARKER, Assistant-Surgeon to University College Hospital. 8vo, with 608 Engravings, 21s.

The Marriage of Near Kin, Considered with respect to the Laws of Nations, Results of Experience, and the Teachings of Biology. By ALFRED H. HUTH. 8vo, 14s.

Medical Jurisprudence: Its Principles and Practice. By ALFRED S. TAYLOR, M.D., F.R.C.P., F.R.S. Second Edition. 2 vols. 8vo, with 189 Engravings, £1 11s. 6d.

By the same Author.

A Manual of Medical Jurisprudence. Tenth Edition. Crown 8vo, with 55 Engravings, 14s.

Also.

Poisons, In Relation to Medical Jurisprudence and Medicine. Third Edition. Crown 8vo, with 104 Engravings, 16s.

Lectures on Medical Jurisprudence. By FRANCIS OGSTON, M.D., Professor in the University of Aberdeen. Edited by FRANCIS OGSTON, JUN., M.D. 8vo, with 12 Copper Plates, 18s.

A Handy-Book of Forensic Medicine and Toxicology. By W. BATHURST WOODMAN, M.D., F.R.C.P., and C. MEYMOTT TIDY, M.D., F.C.S. 8vo, with 8 Lithographic Plates and 116 Engravings, 31s. 6d.

Microscopical Examination of Drinking Water. By JOHN D. MACDONALD, M.D., F.R.S., Assistant Professor in the Army Medical School. 8vo, with 24 Plates, 7s. 6d.

Sanitary Examinations Of Water, Air, and Food. A Vade-Mecum for the Medical Officer of Health. By CORNELIUS B. FOX, M.D., F.R.C.P. Crown 8vo, with 94 Engravings, 12s. 6d.

Sanitary Assurance: A Lecture at the London Institution. By Prof. F. DE CHAUMONT, F.R.S. With Short Addresses by J. E. ERICHSEN, F.R.S., Sir J. FAYRER, K.C.S.I., and R. BRUDENELL CARTER, F.R.C.S., &c. Royal 8vo, 1s.

A Manual of Practical Hygiene. By E. A. PARKES, M.D., F.R.S. Fifth Edition. By F. DE CHAUMONT, M.D., F.R.S., Professor of Military Hygiene in the Army Medical School. 8vo, with 9 Plates and 112 Engravings, 18s.

Dangers to Health: A Pictorial Guide to Domestic Sanitary Defects. By T. PRIDGIN TEALE, M.A., Surgeon to the Leeds General Infirmary. Third Edition. 8vo, with 70 Lithograph Plates (mostly coloured). 10s.

A Handbook of Hygiene and Sanitary Science. By GEO. WILSON, M.A., M.D., Medical Officer of Health for Mid-Warwickshire. Fourth Edition. Post 8vo, with Engravings, 10s. 6d.

Also.

Healthy Life and Healthy Dwellings: A Guide to Personal and Domestic Hygiene. Fcap, 8vo, 5s.

Contributions to Military and State Medicine. By JOHN MARTIN, L.R.C.S.E., Surgeon Army Medical Department. 8vo, 10s. 6d.

Pay Hospitals and Paying Wards throughout the World. By HENRY C. BURDETT, late Secretary to the Seamen's Hospital Society. 8vo, 7s.

By the same Author.

Cottage Hospitals — General, Fever, and Convalescent: Their Progress, Management, and Work. Second Edition, with many Plans and Illustrations. Crown 8vo, 14s.

Dress: Its Sanitary Aspect. A Paper read before the Brighton Social Union, Jan. 30, 1880. By BERNARD ROTH, F.R.C.S. 8vo, with 8 Plates, 2s.

Manual of Anthropometry: A Guide to the Measurement of the Human Body, containing an Anthropometrical Chart and Register, a Systematic Table of Measurements, &c. By CHARLES ROBERTS, F.R.C.S. 8vo, with numerous Illustrations and Tables, 6s. 6d.

Madness: In its Medical, Legal, and Social Aspects. Lectures by EDGAR SHEPPARD, M.D., M.R.C.P., Professor of Psychological Medicine in King's College. 8vo, 6s. 6d.

Idiocy and Imbecility. By WILLIAM W. IRELAND, M.D., Medical Superintendent of the Scottish National Institution for the Education of Imbecile Children at Larbert, Stirlingshire. 8vo, with Engravings, 14s.

A Manual of Psychological Medicine: With an Appendix of Cases. By JOHN C. BUCKNILL, M.D., F.R.S., and D. HACK TUKE, M.D., F.R.C.P. Fourth Edition. 8vo, with 12 Plates (30 Figures) and Engravings, 25s.

The Student's Guide to the Practice of Midwifery. By D. LLOYD ROBERTS, M.D., F.R.C.P., Physician to St. Mary's Hospital, Manchester. Second Edition. Fcap. 8vo, with 111 Engravings, 7s.

Handbook of Midwifery for Midwives: from the Official Handbook for Prussian Midwives. By J. E. BURTON, L.R.C.P. Lond., Senior Assistant Medical Officer, Ladies' Charity, &c., Liverpool. With Engravings. Fcap. 8vo, 6s.

Lectures on Obstetric Operations: Including the Treatment of Hæmorrhage, and forming a Guide to the Management of Difficult Labour. By ROBERT BARNES, M.D., F.R.C.P., Obstetric Physician to St. George's Hospital. Third Edition. 8vo, with 124 Engravings, 18s.

By the same Author.

A Clinical History of Medical and Surgical Diseases of Women. Second Edition. 8vo, with 181 Engravings, 28s.

West on the Diseases of Women. Fourth Edition, revised and in part re-written by the Author, with numerous Additions by J. MATTHEWS DUNCAN, M.D., Obstetric Physician to St. Bartholomew's Hospital. 8vo, 16s.

Observations on the Cæsarean Section, Craniotomy, and on other Obstetric Operations, with Cases. By THOMAS RADFORD, M.D., late Honorary Consulting Physician; St. Mary's Hospital, Manchester. Second Edition, with Plates. 8vo, 10s.

Clinical Lectures on Diseases of Women: Delivered in St. Bartholomew's Hospital, by J. MATTHEWS DUNCAN, M.D., F.R.S.E. 8vo, 8s.

By the same Author.

Papers on the Female Perineum, &c. 8vo, 6s.

The Principles and Practice of Gynæcology. By THOMAS ADDIS EMMET, M.D., Surgeon to the Woman's Hospital, New York. Second Edition. Royal 8vo, with 133 Engravings, 24s.

The Student's Guide to the Diseases of Women. By ALFRED L. GALABIN, M.D., F.R.C.P., Assistant Obstetric Physician to Guy's Hospital. Second Edition. Fcap. 8vo, with 70 Engravings, 7s. 6d.

Notes on the Diseases of Women. Specially designed for Students preparing for Examination. By J. J. REYNOLDS, M.R.C.S. Fcap. 8vo, 2s. 6d.

By the same Author.

Notes on Midwifery: Specially designed to assist the Student in preparing for Examination. Fcap. 8vo, 4s.

Practical Gynæcology: A Handbook of the Diseases of Women. By HEYWOOD SMITH, M.D. Oxon., Physician to the Hospital for Women and to the British Lying-in Hospital. Second Edition. Crown 8vo, with Engravings. (*In the Press.*)

By the same Author.

Dysmenorrhea, its Pathology and Treatment. Crown 8vo, with Engravings, 4s. 6d.

Obstetric Aphorisms: For the Use of Students commencing Midwifery Practice. By JOSEPH G. SWAYNE, M.D. Seventh Edition. Fcap. 8vo, with Engravings, 3s. 6d.

Obstetric Medicine and Surgery: Their Principles and Practice. By F. H. RAMSBOTHAM, M.D., F.R.C.P. Fifth Edition. 8vo, with 120 Plates, 22s.

A Complete Handbook of Obstetric Surgery. Giving Short Rules of Practice in every Emergency. By CHARLES CLAY, late Senior Surgeon to St. Mary's Hospital, Manchester. Third Edition. Fcap. 8vo, with 91 Engravings, 6s. 6d.

Schroeder's Manual of Midwifery, including the Pathology of Pregnancy and the Puerperal State. Translated by CHARLES H. CARTER, B.A., M.D. 8vo, with Engravings, 12s. 6d.

Influence of Posture on Women in Gynecic and Obstetric Practice. By J. H. AVELING, M.D., Physician to the Chelsea Hospital for Women. 8vo, 6s.

A Handbook of Uterine Therapeutics, and of Diseases of Women. By E. J. TILT, M.D., M.R.C.P. Fourth Edition. Post 8vo, 10s.

By the same Author.

The Change of Life In Health and Disease: a Practical Treatise on the Nervous and other Affections incidental to Women at the Decline of Life. Third Edition. 8vo, 10s. 6d.

Ovarian and Uterine Tumours: Their Diagnosis and Surgical Treatment. By T. SPENCER WELLS, F.R.C.S., Consulting Surgeon to the Samaritan Hospital. 8vo, with Engravings. (*Nearly ready.*)

Rupture of the Female Perineum: Its Treatment, immediate and remote. By GEORGE G. BANTOCK, M.D., Surgeon to the Samaritan Hospital. 8vo, with 2 Plates, 3s. 6d.

Chronic Disease of the Heart: Its Bearings upon Pregnancy, Parturition, and Childbed. By ANGUS MACDONALD, M.D., F.R.S.E., Physician to the Edinburgh Royal Infirmary. 8vo, with Engravings, 8s. 6d.

The Female Pelvic Organs, Their Surgery, Surgical Pathology, and Surgical Anatomy, in a Series of Coloured Plates taken from Nature: with Commentaries, Notes, and Cases. By HENRY SAVAGE, Consulting Officer of the Samaritan Free Hospital. Fifth Edition. 4to. (*Nearly ready.*)

Lectures on Diseases of the Nervous System, especially in Women. By S. WEIR MITCHELL, M.D., Physician to the Philadelphia Infirmary for Diseases of the Nervous System. With 5 Plates. Post 8vo, 8s.

A Treatise on the Diseases of Children. For Practitioners and Students. By WILLIAM H. DAY, M.D., Physician to the Samaritan Hospital for Women and Children. Crown 8vo, 12s. 6d.

The Wasting Diseases of Children. By EUSTACE SMITH, M.D., Physician to the King of the Belgians, Physician to the East London Hospital for Children. Third Edition. Post 8vo, 8s. 6d.

By the same Author.

Clinical Studies of Disease in Children. Second Edition. Post 8vo. (*In the Press.*)

Infant Feeding and its Influence on Life; or, the Causes and Prevention of Infant Mortality. By C. H. F. ROUTH, M.D., Senior Physician to the Samaritan Hospital. Third Edition. Fcap. 8vo, 7s. 6d.

A Practical Manual of the Diseases of Children. With a Formulary. By EDWARD ELLIS, M.D. Fourth Edition. Crown 8vo, 10s.

By the same Author.

A Manual of what every Mother should know. Fcap. 8vo, 1s. 6d.

Lectures on Nursing. By W. R. SMITH, M.B., Physician to the Cheltenham Dispensary. Third Edition. Post 8vo, with Engravings. (*In the Press.*)

A Manual for Hospital Nurses and others engaged in Attending on the Sick. By EDWARD J. DOMVILLE, Surgeon to the Exeter Lying-in Charity. Fourth Edition. Crown 8vo, 2s. 6d.

The Nurse's Companion: A Manual of General and Monthly Nursing. By CHARLES J. CULLINGWORTH, Surgeon to St. Mary's Hospital, Manchester. Second Edition. Fcap. 8vo. (*In the Press.*)

Handbook for Nurses for the Sick. By ZEPHERINA P. VEITCH. Second Edition. Crown 8vo, 3s. 6d.

Notes on Fever Nursing. By J. W. ALLAN, M.B., Superintendent and Physician, City of Glasgow Fever Hospital. Crown 8vo, with Engravings, 2s. 6d.

Medicinal Plants: Being descriptions, with original figures, of the Principal Plants employed in Medicine, and an account of their Properties and Uses. By Professor BENTLEY and Dr. H. TRIMEN. In 4 volumes, large 8vo, with 306 Coloured Plates, bound in Half Morocco, Gilt Edges. £11 11s.

Royle's Manual of Materia Medica and Therapeutics. Sixth Edition, by JOHN HARLEY, M.D., Physician to St. Thomas's Hospital. Crown 8vo, with 139 Engravings, 15s.

A Manual of Practical Therapeutics. By E. J. WARING, C.B., M.D., F.R.C.P. Lond. Third Edition. Fcap. 8vo, 12s. 6d.

The Student's Guide to Materia Medica. By JOHN C. THOROWGOOD, M.D., F.R.C.P. Fcap. 8vo, 6s. 6d.

Materia Medica and Therapeutics. By CHARLES D. F. PHILLIPS, M.D., late Lecturer on Materia Medica and Therapeutics to Westminster Hospital.

Vol. 1—Vegetable Kingdom. 8vo, 15s.
Vol. 2—Inorganic Substances. 8vo, 21s.

Bazaar Medicines of India, And Common Medical Plants: With Full Index of Diseases, indicating their Treatment by these and other Agents procurable throughout India, &c. By E. J. WARING, C.B., M.D., F.R.C.P. Third Edition. Fcap. 8vo, 5s.

Indian Notes. The Voyage out; Travelling in India; Upper India; Stations; The Hills; Mineral Waters; Herbs and Simples. By F. R. HOGG, M.D., Surgeon-Major. Crown 8vo, 5s.

The National Dispensatory: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States and Great Britain and Germany, with numerous references to the French Codex. By ALFRED STILLÉ, M.D., LL.D., and JOHN M. MAISCH, Ph.D. Second Edition. 8vo, with 239 Engravings, 34s.

Binz's Elements of Therapeutics: A Clinical Guide to the Action of Drugs. Translated by E. I. SPARKS, M.B., F.R.C.P. Crown 8vo, 8s. 6d.

A Companion to the British Pharmacopœia. By PETER SQUIRE, F.L.S., assisted by his sons, P. W. and A. H. SQUIRE. Thirteenth Edition. 8vo. (*In the Press.*)

By the same Author.

The Pharmacopœias of the London Hospitals, arranged in Groups for Easy Reference and Comparison. Fourth Edition. 18mo, 6s.

A New System of Medicine; Entitled Recognisant Medicine, or the State of the Sick. By B. BOSE, M.D., Indian Medical Service. 8vo, 10s. 6d.

By the same Author.

Principles of Rational Therapeutics. Commenced as an Inquiry into the Relative Value of Quinine and Arsenic in Ague. Crown 8vo, 4s. 6d.

Diseases of Tropical Climates, And their Treatment: with Hints for the Preservation of Health in the Tropics. By JAMES A. HORTON, M.D., Surgeon-Major. Second Edition. Post 8vo, 12s. 6d.

Tropical Dysentery and Chronic Diarrhœa—Liver Abscess — Malarial Cachexia—Insolation—with other forms of Tropical Diseases, &c. By Sir JOSEPH FAYRER, K.C.S.I., M.D., 8vo., 15s.

By the same Author.

Clinical and Pathological Observations in India. 8vo, with Engravings, 20s.

Endemic Diseases of Tropical Climates, with their Treatment. By JOHN SULLIVAN, M.D. Post 8vo, 6s.

Family Medicine for India: By WILLIAM J. MOORE, M.D., Honorary Surgeon to the Viceroy of India. Published under the Authority of the Government of India. Third Edition. Post 8vo, with 66 Engravings, 12s.

By the same Author.

Health Resorts for Tropical Invalids, in India, at Home, and Abroad. Post 8vo, 5s.

The Elements of Indian Hygiene. Intended to guide the Public in acquiring some knowledge in the all-important subject of the Preservation of Health and Prevention of Sickness. By JOHN C. LUCAS, F.R.C.S., H.M.'s Indian Medical Service. Crown 8vo, with Map of India, &c., 5s.

The Student's Guide to the Practice of Medicine. By MATTHEW CHARTERIS, M.D., Professor of Materia Medica in the University of Glasgow. Third Edition. Fcap. 8vo, with Engravings on Copper and Wood, 7s.

Hooper's Physicians' Vade-Mecum. A Manual of the Principles and Practice of Physic. Tenth Edition. By W. A. GUY, F.R.C.P., F.R.S., and J. HARLEY, M.D., F.R.C.P. With 118 Engravings. Fcap. 8vo, 12s. 6d.

Clinical Studies: Illustrated by Cases observed in Hospital and Private Practice. By Sir J. ROSE CORMACK, M.D., F.R.S.E., Physician to the Hertford British Hospital of Paris. Two vols. Post 8vo, 20s.

Clinical Medicine: Lectures and Essays. By BALTHAZAR FOSTER, M.D., F.R.C.P. Lond., Professor of Medicine in Queen's College, Birmingham. 8vo, 10s. 6d.

Clinical Lectures and Cases, with Commentaries. By HENRY THOMPSON, M.D., F.R.C.P., Consulting Physician to Middlesex Hospital. With Temperature Charts. 8vo, 7s. 6d.

Clinical Medicine: A Systematic Treatise on the Diagnosis and Treatment of Disease. By AUSTIN FLINT, M.D., Professor of Medicine in the Bellevue Hospital Medical College. 8vo, 20s.

By the same Author.

Phthisis: In a series of Clinical Studies. 8vo, 16s.

Transfusion of Human Blood: With Table of 50 cases. By Dr. ROUSSEL, of Geneva. With a Preface by Sir JAMES PAGET, Bart. Crown 8vo, 2s. 6d.

The Spectroscope in Medicine. By CHARLES A. MACMUNN, B.A., M.D. 8vo, with 3 Chromo-lithographic Plates of Physiological and Pathological Spectra, and 13 Engravings, 9s.

The Microscope in Medicine. By LIONEL S. BEALE, M.B., F.R.S., Physician to King's College Hospital. Fourth Edition. 8vo, with 86 Plates, 21s.

Also.

On Slight Ailments: Their Nature and Treatment. 8vo, 5s.

A Manual of Medical Diagnosis. By A. W. BARCLAY, M.D., F.R.C.P., Physician to St. George's Hospital. Third Edition. Fcap. 8vo, 10s. 6d.

The Student's Guide to Medical Diagnosis. By SAMUEL FENWICK, M.D., F.R.C.P., Physician to the London Hospital. Fifth Edition. Fcap. 8vo, with 111 Engravings, 7s.

By the same Author.

The Student's Outlines of Medical Treatment. Second Edition. Fcap. 8vo, 7s.

Also.

On Chronic Atrophy of the Stomach, and on the Nervous Affections of the Digestive Organs. 8vo, 8s.

The Student's Guide to Medical Case-Taking. By FRANCIS WARNER, M.D., Assistant Physician to the London Hospital. Fcap. 8vo, 5s.

Notes on Asthma: Its Forms and Treatment. By JOHN C. THOROWGOOD, M.D., Physician to the Hospital for Diseases of the Chest, Victoria Park. Third Edition. Crown 8vo, 4s. 6d.

Observations on the Result of Treatment of nearly One Hundred Cases of Asthma. By T. L. PRIDHAM, M.R.C.S. Third Edition. 8vo, 2s. 6d.

Diseases of the Chest: Contributions to their Clinical History, Pathology, and Treatment. By A. T. HOUGHTON WATERS, M.D., Physician to the Liverpool Royal Infirmary. Second Edition. 8vo, with Plates, 15s.

Winter Cough: (Catarrh, Bronchitis, Emphysema, Asthma). By HORACE DOBELL, M.D., Consulting Physician ot the Royal Hospital for Diseases of the Chest. Third Edition. 8vo, with Coloured Plates, 10s. 6d.

By the same Author.

Loss of Weight, Blood-Spitting, and Lung Disease. Second Edition, to which is added Part VI., "On the Functions and Diseases of the Liver." 8vo, with Chromo-lithograph, 10s. 6d.

Also.

The Mont Dore Cure, and the Proper Way to Use it. 8vo, 7s. 6d.

Relapse of Typhoid Fever, especially with reference to the Temperature. By J. PEARSON IRVINE, M.D., F.R.C.P., late Assistant Physician to Charing Cross Hospital. 8vo, with Engravings, 6s.

Croonian Lectures on Some Points in the Pathology and Treatment of Typhoid Fever. By WILLIAM CAYLEY, M.D., F.R.C.P., Physician to the Middlesex and the London Fever Hospitals. Crown 8vo, 4s. 6d.

Diseases of the Heart and Aorta: Clinical Lectures. By GEORGE W. BALFOUR, M.D., F.R.C.P., and F.R.S. Edin., Senior Physician to, and Lecturer on Clinical Medicine in, the Royal Infirmary, Edinburgh. Second Edition. 8vo, with Chromo-Lithograph and Wood Engravings, 12s. 6d.

On Diseases of the Heart. By THOS. B. PEACOCK, M.D., F.R.C.P. (1) Malformations. 8vo, 10s. (2) Causes and Effects of Valvular Disease. 8vo, 5s. (3) Prognosis in Valvular Disease. 8vo, 3s. 6d.

Manual of the Physical Diagnosis of Diseases of the Heart, including the use of the Sphygmograph and Cardiograph. By ARTHUR E. SANSOM, M.D., F.R.C.P., Assistant-Physician to the London Hospital. Third Edition. Fcap. 8vo, with 48 Engravings, 7s. 6d.

By the same Author.

The Antiseptic System in Medicine and Surgery: A Treatise on Carbolic Acid and its Compounds, etc. With 9 Plates (42 Figures), 8vo, 10s. 6d.

Medical Ophthalmoscopy: A Manual and Atlas. By WILLIAM R. GOWERS, M.D., F.R.C.P., Assistant Professor of Clinical Medicine in University College, and Senior Assistant-Physician to the Hospital. Second Edition, with Coloured Autotype and Lithographic Plates and Woodcuts. 8vo., 18s.

By the same Author.

Epilepsy, and other Chronic Convulsive Diseases: Their Causes, Symptoms, and Treatment. 8vo, 10s. 6d.

Also.

Pseudo-Hypertrophic Muscular Paralysis: A Clinical Lecture. 8vo, with Engravings and Plate, 3s. 6d.

Also.

The Diagnosis of Diseases of the Spinal Cord. Second Edition. 8vo, with Coloured Plate and Engravings, 4s. 6d.

The Sympathetic System of Nerves: Their Physiology and Pathology. By Professor EULENBURG and Dr. P. GUTTMANN. Translated by A. NAPIER, M.D., F.F.P.S. 8vo, 5s. 6d.

Studies on Functional Nervous Disorders. By C. HANDFIELD JONES, M.B., F.R.S., Physician to St. Mary's Hospital. Second Edition. 8vo, 18s.

Diseases of the Stomach: The Varieties of Dyspepsia, their Diagnosis and Treatment. By S. O. HABERSHON, M.D., F.R.C.P., late Senior Physician to Guy's Hospital. Third Edition. Crown 8vo, 5s.

By the same Author.

Pathology of the Pneumogastric Nerve, being the Lumleian Lectures for 1876. Post 8vo, 3s. 6d.

Also.

Diseases of the Abdomen, Comprising those of the Stomach and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. Third Edition. 8vo, with 5 Plates, 21s.

Gout, Rheumatism, And the Allied Affections; with a Chapter on Longevity and the Causes Antagonistic to it. By PETER HOOD, M.D. Second Edition. Crown 8vo, 10s. 6d.

Notes on Rheumatism. By JULIUS POLLOCK, M.D., F.R.C.P., Senior Physician to the Charing Cross Hospital. Second Edition. Fcap. 8vo, with Engravings, 3s. 6d.

A Treatise on the Diseases of the Nervous System. By JAMES ROSS, M.D., Assistant-Physician to the Manchester Royal Infirmary. Two vols., 8vo, with Lithographs, Photographs, and 280 Wood Engravings. 42s.

Lectures on Diseases of the Nervous System. By SAMUEL WILKS, M.D., F.R.S., Physician to, and Lecturer on Medicine at, Guy's Hospital. Second Edition. 8vo. (*In the Press.*)

Nervous Diseases: Their Description and Treatment. A Manual for Students and Practitioners of Medicine. By ALLEN MCLANE HAMILTON, M.D., Physician at the Epileptic and Paralytic Hospital, Blackwell's Island, New York. Second Edition. Royal 8vo, with 72 Illustrations. 16s.

Headaches: Their Nature, Causes, and Treatment. By WILLIAM H. DAY, M.D., Physician to the Samaritan Hospital for Women and Children. Third Edition. Crown 8vo, with Engravings, 6s. 6d.

Fits: Diagnosis and Immediate Treatment of Cases of Insensibility and Convulsions. By JOHN H. WATERS, M.D., K.C., St.G.C., Surgeon to the C Division of Metropolitan Police. Crown 8vo, bound in leather, 4s.

On Megrim, Sick Headache and some Allied Disorders: a Contribution to the Pathology of Nerve Storms. By E. LIVEING, M.D., F.R.C.P. 8vo, 15s.

Nutrition in Health and Disease: A Contribution to Hygiene and to Clinical Medicine. By HENRY BENNET, M.D. Third (Library) Edition. 8vo, 7s. Cheap Edition. Fcap. 8vo, 2s. 6d.

Food and Dietetics, Physiologically and Therapeutically Considered. By F. W. PAVY, M.D., F.R.S., Physician to Guy's Hospital. Second Edition. 8vo, 15s.

By the same Author.

Croonian Lectures on Certain Points connected with Diabetes. 8vo, 4s. 6d.

Imperfect Digestion: Its Causes and Treatment. By A. LEARED, M.D., Sixth Edition. Fcap. 8vo, 4s. 6d.

Indigestion: What it is; what it leads to; and a New Method of Treating it. By JOHN B. GILL, M.D., formerly Surgeon to the Dover Hospital, &c. Second Edition. Fcap. 8vo, 4s. 6d.

The Climate of the Undercliff, Isle of Wight, as deduced from forty years' consecutive Meteorological Observations. By J. L. WHITEHEAD, M.D. Royal 8vo, 5s.

The Riviera: Sketches of the Health-Resorts of the North Mediterranean Coast of France and Italy, from Hyères to Spezia; with Chapters on the General Meteorology of the District, its Medical Aspect and Value, &c. By EDWARD I. SPARKS, M.B., F.R.C.P. Crown 8vo, 8s. 6d.

Winter and Spring On the Shores of the Mediterranean, By HENRY BENNET, M.D. Fifth Edition. Post 8vo, with numerous Plates, Maps, and Engravings, 12s. 6d.

By the same Author.

Treatment of Pulmonary Consumption by Hygiene, Climate, and Medicine. Third Edition. 8vo, 7s. 6d.

The Ocean as a Health-Resort: A Practical Handbook of the Sea, for the use of Tourists and Health-Seekers. By WILLIAM S. WILSON, L.R.C.P., Second Edition, with Chart of Ocean Routes, &c. Crown 8vo, 7s. 6d.

Davos Platz, and the Effects of High Altitude on Phthisis. By ALFRED WISE, M.D. Fcap. 8vo, 2s. 6d.

Principal Health-Resorts Of Europe and Africa, and their Use in the Treatment of Chronic Diseases. By THOMAS MORE MADDEN, M.D., M.R.I.A. 8vo, 10s.

Handbook of Medical and Surgical Electricity. By HERBERT TIBBITS, M.D., F.R.C.P.E., Senior Physician to the West London Hospital for Paralysis and Epilepsy. Second Edition. 8vo, with 95 Engravings, 9s.

By the same Author.

A Map of Ziemssen's Motor Points of the Human Body: A Guide to Localised Electrisation. Mounted on Rollers, 35 × 21. With 20 Illustrations, 5s.

Lectures on the Clinical Uses of Electricity. By J. RUSSELL REYNOLDS, M.D., F.R.S., Physician to University College Hospital. Second Edition. Post 8vo, 3s. 6d.

A System of Practical Surgery. By Sir WILLIAM FERGUSSON, Bart., F.R.S. Fifth Edition. 8vo, with 463 Engravings, 21s.

Surgical Emergencies: Together with the Emergencies Attendant on Parturition and the Treatment of Poisoning. By PAUL SWAIN, F.R.C.S., Surgeon to the Royal Albert Hospital, Devonport. Third Edition. Crown 8vo, with 117 Engravings, 5s.

A Course of Operative Surgery. By CHRISTOPHER HEATH, Surgeon to University College Hospital. With 20 Plates drawn from Nature by M. LÉVEILLÉ, and coloured by hand under his direction. Large 8vo, 40s.

By the same Author.

The Student's Guide to Surgical Diagnosis. Fcap. 8vo, 6s. 6d.

Also.

Manual of Minor Surgery and Bandaging. For the use of House Surgeons, Dressers, and Junior Practitioners. Sixth Edition. Fcap. 8vo, with 115 Engravings, 5s. 6d.

Also.

Injuries and Diseases of the Jaws. Second Edition. 8vo, with 164 Engravings, 12s.

Outlines of Surgery and Surgical Pathology. By F. LE GROS CLARK, F.R.S., assisted by W. W. WAGSTAFFE, F.R.C.S. Second Edition. 8vo, 10s. 6d.

The Practice of Surgery:
A Manual. By THOMAS BRYANT, Surgeon to Guy's Hospital. Third Edition. Two vols. Crown 8vo, with 672 Engravings (many being coloured), 28s.

The Surgeon's Vade-Mecum:
A Manual of Modern Surgery. By ROBERT DRUITT, F.R.C.S. Eleventh Edition. Fcap. 8vo, with 369 Engravings, 14s.

Illustrations of Clinical Surgery.
By JONATHAN HUTCHINSON, Senior Surgeon to the London Hospital. In occasional fasciculi. I. to XIV., 6s. 6d. each. Fasciculi I. to X. bound, with Appendix and Index, £3 10s.

The Principles and Practice of Surgery. By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Third Edition. 8vo, with 490 Engravings, 28s.

Surgical Enquiries:
Including the Hastings Essay on Shock, the Treatment of Inflammations, and numerous Clinical Lectures. By FURNEAUX JORDAN, F.R.C.S., Professor of Surgery, Queen's College, Birmingham. Second Edition, with numerous Plates. Royal 8vo, 12s. 6d.

Treatment of Wounds:
Clinical Lectures. By SAMPSON GAMGEE, F.R.S.E., Surgeon to the Queen's Hospital, Birmingham. Crown 8vo, with Engravings, 5s.

By the same Author.

Fractures of the Limbs,
And their Treatment. 8vo, with Plates, 10s. 6d.

On Dislocations and Fractures.
By JOSEPH MACLISE, F.R.C.S. Uniform with "Surgical Anatomy." 36 folio Plates and Text. Cloth, £2 10s.

Lectures on Diseases of Bones and Joints. By CHARLES MACNAMARA, F.R.C.S., Surgeon to, and Lecturer on Surgery at, Westminster Hospital Crown 8vo, with Engravings, 10s. 6d.

Clubfoot:
Its Causes, Pathology, and Treatment. By WM. ADAMS, F.R.C.S., Surgeon to the Great Northern Hospital. Second Edition. 8vo, with 106 Engravings and 6 Lithographic Plates, 15s.

By the same Author.

On Contraction of the Fingers,
and its Treatment by Subcutaneous Operation; and on Obliteration of Depressed Cicatrices, by the same Method. 8vo, with 30 Engravings, 4s. 6d.

Also.

Lateral and other Forms of Curvature of the Spine: Their Pathology and Treatment. Second Edition. 8vo, with 5 Lithograph Plates and 72 Wood Engravings, 10s. 6d.

Osteotomy:
With an Enquiry into the Etiology and Pathology of Knock-knee, Bow-leg, and other Osseous Deformities of the Lower Limbs. By WILLIAM MACEWEN, M.D., Surgeon and Lecturer on Clinical Surgery to the Glasgow Royal Infirmary. 8vo, with 51 Engravings, 7s. 6d.

Lectures on Orthopædic Surgery. By BERNARD E. BRODHURST, F.R.C.S., Surgeon to the Royal Orthopædic Hospital. Second Edition. 8vo, with Engravings, 12s. 6d.

By the same Author.

On Anchylosis, and the Treatment for the Removal of Deformity and the Restoration of Mobility in Various Joints. Fourth Edition. 8vo, with Engravings, 5s.

Orthopædic Surgery,
And Diseases of the Joints. By L. A. SAYRE, M.D., Professor of Orthopædic Surgery in Bellevue Hospital Medical College. 8vo, with 274 Engravings, 20s.

Orthopraxy:
The Mechanical Treatment of Deformities, Debilities, and Deficiencies of the Human Frame. By H. HEATHER BIGG, Assoc. Inst. C.E. Third Edition. 8vo, with 319 Engravings, 15s.

The Orthopragms of the Spine:
An Essay on the Curative Mechanisms applicable to Spinal Curvature, etc. By ROBERT HEATHER BIGG, Assoc. Inst. C.E. 8vo, with Engravings, 5s.

A Manual of the Principles and Practice of Ophthalmic Medicine and Surgery. By T. WHARTON JONES, F.R.C.S., F.R.S. Third Edition. Fcap. 8vo, with 9 Coloured Plates and 173 Engravings, 12s. 6d.

On Diseases and Injuries of the Eye: A Course of Systematic and Clinical Lectures to Students and Medical Practitioners. By J. R. WOLFE, M.D., F.R.C.S.E., Senior Surgeon to the Glasgow Ophthalmic Institution; Lecturer on Ophthalmic Medicine and Surgery in Anderson's College. With 10 Coloured Plates and 157 Wood Engravings. 8vo, £1 1s.

Hints on Ophthalmic Out-Patient Practice. By CHARLES HIGGENS, Ophthalmic Assistant-Surgeon to, and Lecturer on Ophthalmology at, Guy's Hospital. Second Edition. Fcap. 8vo, 3s.

Liebreich's Atlas of Ophthalmoscopy: Composed of 12 Chromolithographic Plates (containing 59 Figures). The Text translated by H. ROSBOROUGH SWANZY, M.B. Second Edition. 4to, 30s.

The Student's Guide to Diseases of the Eye. By EDWARD NETTLESHIP, F.R.C.S., Ophthalmic Surgeon to St. Thomas's Hospital. Second Edition. Fcap. 8vo, with Engravings, (*In the Press.*)

A Manual of Diseases of the Eye. By C. MACNAMARA, F.R.C.S., Surgeon to Westminster Hospital. Third Edition. Fcap. 8vo, with Coloured Plates and Engravings, 12s. 6d.

Glaucoma:
Its Causes, Symptoms, Pathology, and Treatment. By PRIESTLEY SMITH, M.R.C.S., Ophthalmic Surgeon to the Queen's Hospital, Birmingham. 8vo, with Lithographic Plates, 10s. 6d.

A Manual of Ophthalmoscopy for the use of Students. By DR. DAGUENET. Translated by C. S. JEAFFRESON, Surgeon to the Newcastle-on-Tyne Eye Infirmary. With Engravings. Fcap. 8vo, 5s.

Essays in Ophthalmology.
By GEORGE E. WALKER, F.R.C.S., Surgeon to St. Paul's Eye and Ear Hospital, &c., Liverpool. Post 8vo, 6s.

Hare-Lip and Cleft Palate.
By FRANCIS MASON, F.R.C.S., Surgeon to, and Lecturer on Practical Surgery at, St. Thomas's Hospital. 8vo, with 66 Engravings, 6s.

By the same Author.

The Surgery of the Face.
8vo, with 100 Engravings, 7s. 6d.

A Practical Treatise on Aural Surgery. By H. MACNAUGHTON JONES, M.D., Professor of the Queen's University in Ireland, Surgeon to the Cork Ophthalmic and Aural Hospital. Second Edition. Crown 8vo, with 63 Engravings, 8s. 6d.

By the same Author.

Atlas of Diseases of the Membrana Tympani. In Coloured Plates, containing 62 Figures, with Text. Crown 4to, 21s.

Diseases and Injuries of the Ear. By WILLIAM B. DALBY, F.R.C.S., Aural Surgeon to, and Lecturer on Surgery at, St. George's Hospital. Second Edition. Fcap. 8vo, with Engravings, 6s. 6d.

Lectures on Syphilis of the Larynx (Lesions of the Secondary and Intermediate Stages). By W. MACNEILL WHISTLER, M.D., Physician to the Hospital for Diseases of the Throat and Chest. Post 8vo, 4s.

Diseases of the Throat and Nose. A Manual. By MORELL MACKENZIE, M.D. Lond., Senior Physician to the Hospital for Diseases of the Throat and Chest. Vol. I. Diseases of the Pharynx, Larynx, and Trachea. Post 8vo, with 112 Engravings, 12s. 6d.

By the same Author.

Diphtheria:
Its Nature and Treatment, Varieties, and Local Expressions. 8vo, 5s.

Throat Diseases,
And the Use of the Laryngoscope: A Handbook for Practitioners and Senior Students. By W. DOUGLAS HEMMING, F.R.C.S.E. With Engravings. Fcap. 8vo, 2s. 6d.

The Ear:
Its Anatomy, Physiology, and Diseases. By CHARLES H. BURNETT, A.M., M.D., Aural Surgeon to the Presbyterian Hospital, Philadelphia. 8vo, with 87 Engravings, 18s.

A Treatise on Vocal Physiology and Hygiene, with especial reference to the Cultivation and Preservation of the Voice. By GORDON HOLMES, L.R.C.P. Edin., Physician to the Municipal Throat and Ear Infirmary. Second Edition. With Engravings. Crown 8vo, 6s. 6d.

By the same Author.

A Guide to the Use of the Laryngoscope in General Practice. Crown 8vo, with 15 Engravings, 2s. 6d.

Ear and Throat Diseases.
Essays by LLEWELLYN THOMAS, M.D., Surgeon to the Central London Throat and Ear Hospital. Post 8vo, 2s. 6d.

Sore Throat:
Its Nature, Varieties, and Treatment. By PROSSER JAMES, M.D., Physician to the Hospital for Diseases of the Throat. Fourth Edition. Post 8vo, with Coloured Plates and Engravings, 6s. 6d.

A System of Dental Surgery.
By JOHN TOMES, F.R.S., and CHARLES S. TOMES, M.A., F.R.S. Second Edition. Fcap. 8vo, with 268 Engravings, 14s.

Dental Anatomy, Human and Comparative: a Manual. By CHARLES S. TOMES, M.A., F.R.S. Second Edition. Crown 8vo, with 191 Engravings, 12s. 6d.

A Practical Treatise on Operative Dentistry. By JONATHAN TAFT, D.D.S., Professor in the Ohio College of Dental Surgery. Third Edition. With 134 Engravings. 8vo, 18s.

The Student's Guide to Dental Anatomy and Surgery. By HENRY SEWILL, M.R.C.S., L.D.S. Fcap. 8vo, with 77 Engravings, 5s. 6d.

Dental Materia Medica and Therapeutics. By JAMES STOCKEN, L.D.S. Third Edition. (*In the Press.*)

A Manual of Dental Mechanics. By OAKLEY COLES, L.D.S.R.C.S., Second Edition. Crown 8vo, with 140 Engravings, 7s. 6d.

By the same Author.

Deformities of the Mouth. Third Edition, 8vo, with 83 Wood Engravings and 96 Drawings on Stone, 12s.6d.

Mechanical Dentistry in Gold and Vulcanite. By F. H. BALKWILL, L.D.S.R.C.S. 8vo, with 2 Lithographic Plates and 57 Engravings, 10s.

Lectures on Dermatology: Delivered at the Royal College of Surgeons, by Sir ERASMUS WILSON, F.R.S. 1870, 6s.; 1871–73, 10s. 6d.; 1874–75, 10s. 6d.; 1876–78, 10s. 6d.

Eczema: By MCCALL ANDERSON, M.D., Professor of Clinical Medicine in the University of Glasgow. Third Edition. 8vo, with Engravings, 7s. 6d.

Eczema and its Management: A practical Treatise based on the Study of 2,500 Cases of the Disease. By L. DUNCAN BULKLEY, M.D., Physician for Skin and Venereal Diseases at the New York Hospital. 8vo, 12s. 6d.

Psoriasis, or Lepra. By GEORGE GASKOIN, M.R.C.S., Surgeon to the British Hospital for Diseases of the Skin. 8vo, 5s.

On Certain Rare Diseases of the Skin: being Vol. I of "Lectures on Clinical Surgery." By JONATHAN HUTCHINSON, Senior Surgeon to the London Hospital, and to the Hospital for Diseases of the Skin. 8vo, 10s. 6d.

Leprosy in British Guiana: An Account of West Indian Leprosy. By JOHN D. HILLIS, F.R.C.S., M.R.I.A., Medical Superintendent of the Leper Asylum, British Guiana. Imp. 8vo, with 22 Lithographic Coloured Plates and Wood Engravings. £1 11s. 6d.

Photographic Illustrations of Skin Diseases. Sixty Cases from Life. By GEORGE H. FOX, M.D. 4to, £5 5s.

Cancer Life: Its Causes, Progress, and Treatment. A General and Historical Treatise. By R. MITCHELL, M.R.C.S. 8vo, 7s. 6d.

Cancer of the Breast: By THOMAS W. NUNN, F.R.C.S., Consulting Surgeon to the Middlesex Hospital. 4to, with 21 Coloured Plates, £2 2s.

Atlas of Skin Diseases: By TILBURY FOX, M.D., F.R.C.P. With 72 Coloured Plates. Royal 4to, half morocco, £6 6s.

Certain Forms of Cancer, With a New and Successful Mode of treating it. By A. MARSDEN, Senior Surgeon to the Cancer Hospital. Second Edition. 8vo, with Coloured Plates, 8s. 6d.

On Cancer: Its Allies, and other Tumours, with special reference to their Medical and Surgical Treatment. By F. ALBERT PURCELL, M.D., Surgeon to the Cancer Hospital, Brompton. 8vo, with 21 Engravings, 10s. 6d.

Diseases of the Urinary Organs: Clinical Lectures. By Sir HENRY THOMPSON, F.R.C.S., Emeritus Professor of Clinical Surgery in University College. Fifth Edition. 8vo, with 2 Plates and 71 Engravings, 10s. 6d.

By the same Author.

Diseases of the Prostate: Their Pathology and Treatment. Fourth Edition. 8vo, with numerous Plates, 10s.

Also.

Practical Lithotomy and Lithotrity; or, an Inquiry into the best Modes of Removing Stone from the Bladder. Third Edition. 8vo, with 87 Engravings, 10s.

Also.

The Preventive Treatment of Calculous Disease, and the Use of Solvent Remedies. Second Edition. Fcap. 8vo, 2s. 6d.

Diseases of the Testis, Spermatic Cord, and Scrotum. By THOMAS B. CURLING, F.R.S., Consulting Surgeon to the London Hospital. Fourth Edition. 8vo, with Engravings, 16s.

Fistula, Hæmorrhoids, Painful Ulcer, Stricture, Prolapsus, and other Diseases of the Rectum: Their Diagnosis and Treatment. By WILLIAM ALLINGHAM, Surgeon to St. Mark's Hospital for Fistula. Fourth Edition. 8vo, with Engravings, 10s. 6d.

Hydrocele: Its several Varieties and their Treatment. By SAMUEL OSBORN, late Surgical Registrar to St. Thomas's Hospital. Fcap. 8vo, with Engravings, 3s.

By the same Author.

Diseases of the Testis. Fcap. 8vo, with Engravings. 3s. 6d.

Parasites: A Treatise on the Entozoa of Man and Animals, including some Account of the Ectozoa. By T. SPENCER COBBOLD, M.D., F.R.S. 8vo, with 85 Engravings, 15s.

The Surgery of the Rectum.
By HENRY SMITH, Professor of Surgery in King's College, Surgeon to the Hospital. Fourth Edition. Fcap. 8vo, 5s.

Cancer of the Rectum:
Its Pathology, Diagnosis, and Treatment. By W. HARRISON CRIPPS, F.R.C.S., Surgeon to the Great Northern Hospital, &c. Crown 8vo, with Lithographic Plates, 6s.

Lectures on the Surgical Disorders of the Urinary Organs. By REGINALD HARRISON, F.R.C.S., Surgeon to the Liverpool Royal Infirmary. Second Edition, with 48 Engravings. 8vo, 12s. 6d.

By the same Author.

The Prevention of Stricture and of Prostatic Obstruction. 8vo, with Engravings, 2s. 6d.

Lithotomy and Extraction of Stone. By W. POULETT HARRIS, M.D., Surgeon-Major H.M. Bengal Medical Service. 8vo, with Engravings, 10s. 6d.

Diseases of the Bladder,
Prostate Gland, and Urethra, with a practical view of Urinary Diseases, Deposits, and Calculi. By F. J. GANT, Senior Surgeon to the Royal Free Hospital. Fourth Edition. Crown 8vo, 10s. 6d.

Renal and Urinary Diseases:
Clinical Reports. By WILLIAM CARTER, M.B., Physician to the Liverpool Southern Hospital. Crown 8vo, 7s. 6d.

Pathology of the Urine,
Including a Complete Guide to its Analysis. By J. L. W. THUDICHUM, M.D., F.R.C.P. Second Edition, rewritten and enlarged. 8vo, with Engravings, 15s.

Genito-Urinary Organs, including Syphilis: a Practical Treatise on their Surgical Diseases, designed as a Manual for Students and Practitioners. By W. H. VAN BUREN, M.D., and E. L. KEYES, M.D. Royal 8vo, with 140 Engravings, 21s.

Lectures on Syphilis.
By HENRY LEE, Consulting Surgeon to St. George's Hospital. 8vo, 10s.

Harveian Lectures on Syphilis.
By JAMES R. LANE, F.R.C.S., Surgeon to St. Mary's Hospital. Second Edition. Fcap. 8vo, 3s. 6d.

Photographic Illustrations of Cutaneous Syphilis. Seventy Cases from Life. By GEORGE H. FOX, M.D. 4to, £5 5s.

Urinary and Reproductive Organs: their Functional Diseases. By D. CAMPBELL BLACK, M.D. Second Edition. 8vo, 10s.

A Treatise on Syphilis.
By WALTER J. COULSON, Surgeon to the Lock Hospital and to St. Peter's Hospital for Stone. 8vo, 10s.

By the same Author.

Stone in the Bladder:
Its Prevention, early Symptoms, and Treatment by Lithotrity. 8vo, 6s.

Also.

Coulson on Diseases of the Bladder and Prostate Gland. Sixth Edition. 8vo, 16s.

The Reproductive Organs
In Childhood, Youth, Adult Age, and Advanced Life, considered in their Physiological, Social, and Moral Relations. By WILLIAM ACTON, M.R.C.S. Sixth Edition. 8vo, 12s.

Student's Primer on the Urine.
By J. TRAVIS WHITTAKER, M.D., Clinical Demonstrator at the Royal Infirmary, Glasgow. With 16 Plates etched on Copper. Post 8vo, 4s. 6d.

A Manual of the Laws affecting Medical Men. By ROBERT G. GLENN, LL.B., Barrister-at-Law. 8vo, 14s.

The Medical Adviser in Life Assurance. By EDWARD H. SIEVEKING, M.D., F.R.C.P., Physician to St. Mary's and Lock Hospitals, &c. Crown 8vo, 6s.

A Dictionary of Medical Science:
Containing a concise Explanation of the various Subjects and Terms of Medicine, &c.; Notices of Climate and Mineral Waters; Formulæ for Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonyms. By ROBLEY DUNGLISON, M.D., LL.D. New Edition. Royal 8vo, 28s.

A Medical Vocabulary:
Being an Explanation of all Terms and Phrases used in the various Departments of Medical Science and Practice, giving their Derivation, Meaning, Application, and Pronunciation. By ROBERT G. MAYNE, M.D., LL.D. Fifth Edition. Fcap. 8vo, 10s. 6d.

Abridged Medical Account Books. The "Expedite" Method. By JAMES MACNAB, L.R.C.S.E. *Index Ledger.* Royal 4to. For four years, 21s. *Visiting List.* Cloth, 2s. 6d.; Leather, 3s. 6d.

Medical Education
And Practice in all parts of the World. By HERBERT JUNIUS HARDWICKE, M.D., M.R.C.P. 8vo, 10s.
